Another seedling of Mr. Thomson's, the Golden Lady Downe's, is a very excellent Grape. It is just a white counterpart of the Lady Downe's, whose high merits as a late-keeping Grape are well known. This White variety is a very welcome addition. Mr. Thomson states that it will keep fully longer than the Black variety.—ARCHAMBAUD.

ORCHARD-HOUSE RAILWAY.

I HOPE I may be allowed to make a few remarks upon an article which appeared in your Journal of September 3rd, signed "ARCHAMBAUD," the subject being the orchard houses at Sawbridgeworth. At the latter part of the article your correspondent is kind enough to consider an invention of mine, now at Messrs. Rivers's nurseries, worthy of his notice—namely, "the orchard-house railway." I should not think it necessary to do more than thank him for his courtesy in doing so, were it not for some inaccuracy of statement, arising, no doubt, from his having taken only a superficial view of the question. I hope your correspondent will pardon me for endeavouring to correct this. He says at the close of his remarks, "Granted that it is beneficial to the trees to have the fresh air, they can easily be carried out if necessary, and that at one-twentieth part of the expense." Now, I hope he does not think me so absurd as to deem it necessary to incur this expense merely for one removal of the trees into the open air to ripen their fruit in the summer, which his comparison of figures implies; the fact being that it is used constantly through the whole year, and especially for Apricots, also for Peaches, Nectarines, Plums, and Pears, and brings them to such perfection in respect to the flavour of the fruit, largeness of the leaves, and general appearance of the trees, as I have never seen in any orchard house.

Now, as the outcry has constantly been want of flavour in too large a proportion of the crop, this is at least worth a consideration—a pause, before condemnation is carelessly administered. There is no doubt that flavour diminishes as you recede from the ventilators (I think your correspondent admits this in his article); nor will top ventilation remedy this. But even taking the position "ARCHAMBAUD" assumes, that the railway is only required for one removal, and that the expense in consequence is twenty times as much, the summing-up of his statistics in the next sentence rather contradicts it—"It just resolves itself into this, whether a tree is to cost 5s. a-year or 50s., as by this plan." But this is only ten times as much. If he were to halve it again he would be beside the mark. I hope he will forgive me for saying that firing off these random figures like grape shot is calculated to do mischief by misleading; but I quite acquit him of any such intention, and will at once give him credit only for wishing to be understood to say in round numbers that the expense is great.

I am perfectly aware that the first cost is considerable, but he is wrong in stating that it is a yearly expense, exactly the reverse being the case, for after the railway is once made it is guaranteed to last as long as the house, and the yearly saving of labour is very great. Take the case mentioned of removing the trees annually by hand. My gardener engages to say that in the same number of minutes which it would occupy two men to remove the trees by hand from a large house, and plunge them in the garden (where, be it observed, they must continue, whether the weather be good or bad), one man could move the trees in and out of the house fifty times in the course of the year, and this without disturbing the roots in the pans from first to last. These pans all turn upon their axes to expose any side of the tree to the sun, or for pruning also, without disturbing the roots.

It takes a man a considerable time to water all these trees; whereas the time required to give them the benefit (as much or as little as you pleased), of any showers that occurred through the year, to say nothing of the dews in summer nights, would be five minutes; and a strong boy, the lowest help in the garden, could do it without the possibility of making a mistake, unless it were in running the wheels over his toes, and even that little error he would not commit twice. Now, whether natural showers or artificial watering be best for the trees I leave your readers to decide.

The truck at Sawbridgeworth is not placed quite to advantage, being raised on a mound, and consequently exposed too much to the wind. But do not let it be supposed that this was Mr. Rivers's wish. Nothing could exceed the kindness

both of himself and son in trying to find some suitable place in which to fix it; but the ground is so very undulating, and, as may be supposed, in a well-arranged garden like Sawbridgeworth, every available place so preoccupied, that we had great difficulty in arranging it. Now, the man has no small mind who cheerfully admits within his own penetralia an invention which professes, *in limine*, to found its prospect of success upon a flaw (if it may be fairly called so), or rather want, in the great work which he has devoted a long and useful life in bringing to perfection. I appreciate it proportionably, for there is no money question between us. He has tried it this year with "fine old Apricot trees." He tells me the crop was most abundant and of delicious flavour, and that everybody liked it, but sighed over the first cost, which is, after all the fuss made, not nearly what "ARCHAMBAUD" would make out, and nothing to the money John Bull loves to fritter away in cheap failures.

One Apricot tree which had an extraordinarily fine crop of fruit on it, Mr. Rivers had occasion to remove from the pan, and he informed me that the roots had "eaten up the soil," and filled the pan with delicate fibrils. This is exactly what I expected, and consider so desirable—namely, the avoidance of long rosy roots striking deeply into the soil, but at the same time a gentle assistance given in the most natural way from good sweet earth below, unmanured, which of course is renewed every year. This, with the open air in favourable weather, and a rich top-dressing as recommended by Mr. Rivers, gives such flavour to the fruit as cannot be surpassed.

Mr. Rivers has been kind enough to allow me to append a full description of the invention at the end of his new "catalogue," and also new edition of "The Orchard House." I hope "ARCHAMBAUD" will pay me the compliment to read it—aye, and criticise it too, for the invention must be able to hold its own against that, as well as a very large amount of prejudice; but being based upon principles theoretically and practically sound, it must come sooner or later as an assistant to the orchard house in every gentleman's garden, where the gentleman himself understands anything about it, and where certainty of crop combined with fruit of the highest quality, colour, and size, is a desideratum.—J. F., *Southacre Rectory, Brandon.*

DUC DE MALAKOFF STRAWBERRY.

MR. DOUGLAS is convinced that he has the true Duc de Malakoff Strawberry, in which case I cannot have it true. The description given by Mr. Douglas answers better to the foliage here than Mr. Radclyffe's. I received my runners four years since, indirectly from an eminent fruit grower in this county (Lancashire), and I had no doubt as to their being true to name, as plants of the kind were largely grown, and are so up to this day, for market. In general, market gardeners do not like to grow fruit that is soft when ripe, and which, therefore, soon spoils. I believe they are quite alive to their interests in these little matters. However, I do not wish to affirm that the true variety is claimed in this locality, and it is not for the name that I desire to recommend it so strongly, for a name is only a secondary consideration, when you have a good and useful fruit, one that can be depended upon as a general cropper under pot culture, or in the open gardens. I may state that the variety in question is cultivated extensively in this locality, and I feel persuaded it will be grown universally when it becomes better known. I have seen since I wrote the letter which appeared on August 6th, a Duc de Malakoff that answers more to Prince of Wales, which was sent out with several other varieties from one of the leading nurseries in England. The gardener has received plants from me to replace his so-called Duc de Malakoff, which he had been cultivating with much care to bring it to perfection, knowing that it was one of the leading Strawberries grown in this neighbourhood. As for seeing any barren plants, that is out of the question, provided good runners are planted, but it is well to be always careful to select runners from fruiting plants, which will amply pay for care and attention. I generally plant out good runners by the middle of August, and am sure of a crop in the following season in proportion to the foliage. In the second season there has been something like a quart on a plant, and I have seen the variety equally prolific in other gardens.—W. Brooks, *Sandfield Park, Liverpool.*

LILIUM TIGRINUM SPLENDENS.—In your report of what was said at the Royal Horticultural Society's meeting of September

1st on the *Lilium tigrinum splendens*, there is a slight error. Mr. Eyles sent me a single flower from M. Van Houtte's; it was Mr. Allen, of Shepton Mallet, a great Lily cultivator, who informed me that he had bloomed *L. tigrinum splendens*, and considered it a splendid variety. This description was confirmed by Mr. Waterer, who had seen it at M. Van Houtte's. —GEORGE F. WILSON.

THE WHORTLEBERRY TOMATO.

Among the horticultural novelties that have been introduced to this country from the United States is one which is called "The Whortleberry Tomato." We are not aware that it has yet found a place in our seedsmen's catalogues; and lest in the rage for novelties, which is now too much the fashion, it should by any chance be pressed on the notice of our countrymen, we feel it our duty to raise a note of warning of the danger consequent on such an event. This Whortleberry Tomato is neither more nor less than the common Nightshade (*Solanum nigrum*), a weed common in waste or cultivated ground, the berries of which have the reputation of being very deleterious, and have in some instances proved fatal to those who have eaten them. It is true that Dunal, of Montpellier, administered the berries without any serious results, and that in the Isle of Ascension they are used in plum puddings; but when cases are known in which they have caused the death of children who have eaten them, the public cannot be too much on their guard respecting them. All constitutions are not alike, and what would kill one man has sometimes no effect on another.—H.

RULES OF THE AMERICAN POMOLOGICAL SOCIETY.

1. No new seedling fruit shall be entitled to the recommendation of this Society until its qualities shall be ascertained by at least five years' experience in more than one locality, and which is not at least equal to any similar variety of the first rank already known; or which, if only of second-rate flavour, is superior in vigour, hardiness, productiveness, or other important quality or characteristics.

2. No new fruit shall be considered as named until it has been accurately described by some person or committee known to be conversant with existing varieties, and such description shall have been published in at least one horticultural or agricultural journal, or some pomological work of acknowledged standard character.

3. The originator, or he who first makes known a new variety, shall be entitled to name it; and such name, if suitable, shall be adopted by the writer describing the fruit for the first time. But if the name proposed is inappropriate, or does not come within the rules of nomenclature, the describer shall be at liberty to give a name.

When two persons have named or described a fruit, the name and description first published, if according to the rules, shall have the priority.

4. In giving names to new varieties, all harsh, vulgar, or inelegant names, such as "Sheep's-nose" and "Hog-pen," should be avoided; and no name should consist of more than two words, excepting only when the originator's name is added. Characteristic names, or those in some way descriptive of the qualities, origin, or habit of fruit or tree, shall be preferred. They may either be of intrinsic properties, as Golden Sweeting, Downer's Late; or of local origin, as Newtown Pippin, Hudson's Gage; or of the season of ripening, as Early Scarlet, Frost Gage; or of the form and colour, as Golden Drop, Blue Pearmain; or which commemorate a particular place or person, as Tippecanoe, La Grange, Baldwin; or any other titles which may be significantly applied.

5. The descriptions of new varieties of fruits shall embrace the following particulars:—

1st, An account of their origin.

2nd, The fruit, its size, form, and exterior colour, texture, and colour of the flesh, flavour, and time of ripening; with the addition, on stone fruits, of the size of the stone, adherence or non-adherence of the flesh, form of the suture, and the hollow at the stem; and in kernel fruits, of the size of the core and seeds, the length, position, and insertion of the stalk, and form of the eye.

3rd, The tree, its marked characters of growth, young and bearing wood, foliage, and blossoms. In Peaches, the form of

leaf, glands, and size of blossoms; in Strawberries, the character of the blossoms, whether staminate or pistillate; in Grapes, the form of bunch or berry.—P. BARRY, *Chairman*.

ROYAL HORTICULTURAL SOCIETY.

SEPTEMBER 15TH.

FRUIT COMMITTEE.—G. F. Wilson, Esq., F.R.S., in the chair. There was a good display of fruit at this meeting, and especially of Peaches, though these were not on the whole of such large size as we have seen them in other years.

Prizes were offered for the best and second best dishes of Peaches from an open wall, and these were well contested by several competitors. Mr. Earley, gardener to F. Pryor, Esq., Digsall, was first with very good examples of Late Admirable; and Mr. Whiting, of the Deepdene, Dorking, was second with Walburtan Admirable, also good. Late Admirable likewise came from Mr. Bailey, of Shardloes; Barrington, from Mr. Earley, and Mr. Richbell, gardener to L. Heathcote, Esq., Tadworth Court, Epsom, who also sent small fruit of Bellegarde. Mr. Dixon, Holland Park, Kensington, had Yellow Admirable, splendid in colour, but of poor flavour; and Mr. Marcham, gardener to E. Oates, Esq., Hanwell, Chancellor, of medium size and well coloured. Mr. McIndoe, gardener to the Archbishop of York, sent excellent examples of Late Admirable, but they arrived too late for competition.

For the best dish of Nectarines no first prize was awarded, the only exhibitor, Mr. Cox, of Redleaf, taking a second prize for small but very good fruit of Violette d'Italie.

For Apricots, both from walls and orchard houses, prizes were offered, but the date of the meeting was too late for this fruit in such an early season as the present.

For orchard-house Peaches, Mr. Tillery, gardener to the Duke of Portland, was first with very fine examples of Walburtan Admirable; and the second prize went to Mr. Martyn, gardener to S. P. Kennard, Esq., Harrow Weald, for Late Admirable, very fine as regards size and colour, but the flavour tainted by the cotton wadding used in packing. For orchard-house Nectarines, no first prize was awarded, but a second was given to Mr. Tillery, for Rivers's Victoria.

The best three dishes of Plums came from Mr. Cox, of Redleaf, and consisted of Ickworth Imperatrice, Coe's Golden Drop, remarkably fine, and St. Martin's Quetsche. Mr. Whiting was second with Diamond, Coe's Golden Drop, rather small but very good, and Reine Claude de Bavay, which though scarcely ripe enough, was richly flavoured.

Of Figs only two dishes were exhibited, and both were very good. Brown Turkey, or Lee's Perpetual, from Mr. Earley, was awarded the first prize, being rather better ripened than the same kind from Mr. Bailey, who was second.

Among miscellaneous subjects, fine, well-ripened Black Hamburgh and Foster's White Seedling Grapes, grown in ground vineries, were exhibited by C. T. Wells, Esq., of Southend, and received a special certificate. A similar award was made to Mr. Chaff, gardener to A. Smea, Esq., Wallington, near Carshalton, for an exceedingly fine collection of Apples, which, in the rich well-watered soil of that place, had attained a very large size. Putt's Seedling, Blenheim Pippin, Lord Derby, Lord Suffield, and Cellini were especially fine. From Mr. Rivers, of Sawbridgeworth, and Mr. F. Dancer, of Little Sutton, Chiswick, came very fine examples of Belle de Septembre Plum, a first-rate variety for culinary purposes, and the latter also exhibited two other varieties, which were to be subjected to further examination. Transparent Gage, from an orchard house, shrivelled, but of very fine flavour, came from G. F. Wilson, Esq. Mr. Warner, of the Abbey Nurseries, Leicester, sent Warner's Seedling Apple, a large yellowish green sort, but it was not considered to possess sufficient merit to deserve a certificate. From Mr. Richbell came a green-fleshed Melon, but it was unripe; and from Mr. Rust, Bridge Castle, Tunbridge Wells, a seedling Peach, called "The Thompson." It was raised by Miss Thompson, The Rectory, Frant, was highly coloured and of good flavour, and was stated to be very hardy. Very good examples of Beurre Hardy Pear, and of excellent flavour, were shown by Mr. Whiting, likewise Ingram's Golden Russet Pear. Mr. Turner, of Slough, sent fine samples of Paterson's Victoria and Regent Potatoes, which it was requested should be sent again, when they could be cooked; and Messrs. Stuart & Mein, Kelso, a Kidney Bean with large deep violet purple pods, which is said to be very ornamental and profitable, besides being useful. Its colour when cooked is said to be brown. J. R. Reeves, Esq., Woodhayes, Wimbledon, exhibited two gigantic Potatoes (*Lycopersicon bovista*?), grown in the kitchen garden there, and measuring at least 8 or 10 inches in diameter.

FLORAL COMMITTEE.—On this occasion there was a varied and interesting lot of plants staged, though not so numerous as at the past two or three meetings. From Mr. J. Wood, Hockliffe, Danstale, came a variegated form of *Solanum dalecarlica*, or the Bittersweet, the leaves broadly edged with pale yellow, as in the case of *Ageratum mexicanum variegatum*; it was awarded a second-class certificate. From Mr. W. Bull came an interesting collection of plants, including *Alternanthera amabilis*, which appeared to be a larger and more robust form of *A. spatulata*, and the Committee desired to see it again; *Skimmia oblata* in berry, which is quite hardy and makes a

good decorative shrub; a large specimen of *Monstera deliciosa* in flower; *Annyllis Josephina lateritia*, with a large truss of pale reddish flowers, &c. A special certificate was awarded to the group. From Mr. William Holah, The Gardens, Rufford Abbey, Ollerton, came a plant of a yellow bedding Pansy, which he has used this season with great effect, but which did not appear to differ from the Cliveden Yellow bedding kind.

A very interesting group of plants was also furnished by Messrs. Veitch & Sons, including *Ficus dealbata*, which bears an excellent character, but the specimen shown was considered too small to justify the Committee in giving it an award; *Maranta Wallii* with bright pale green leaves, having patches of dark shading; *M. Wagneri*, in the way of fasciated, but not so good or so bright-looking as *M. roseopicta* and others; *M. Baranquiana*, considered to be no improvement on the old vittata; *Guzmania tricolor*, an old plant, in flower, but well grown; *Chirita sinensis foliis variegatis*, the foliage slightly pale-veined, but the veining said to be often more apparent on the leaves; *Sinningia purpurea major*, a cool stone plant, with ornamental foliage, having a greenish bronze colour on the upper side of the leaves, and red on the under side, scarcely striking in character as shown; *Alsophila Van Geertii*, a distinct and handsome Fern, but some doubt being expressed as to its being an *Alsophila*, it was requested to be sent again; *Caladium Anguste Riviere*, a distinct and beautiful kind, the bright green leaves stained and blotched with carmine, very handsome and effective, and deservedly awarded a first-class certificate; *Caladium Lucy*, the leaves stained red; *Yucca albo-spica*, the long lance-shaped and somewhat drooping leaves having white filaments on either side, also awarded a first-class certificate; *Allamanda nobilis* in bloom; some specimens of *Odontoglossum grande*; the beautiful *Cattleya Dominiana alba*; a small plant of the handsome *Hippocrastum pardinum*, with two fine flowers; the curious *Masdevallia Veitchiana*, &c. A special certificate was awarded to the group.

Mr. William Paul, Waltham Cross, sent *Aucuba salicifolia*, a slender-leaved form of the *A. longifolia* type, the character not sufficiently developed. Mr. Paul also contributed a charming collection of cut Roses, among which the light flowers predominated, and a large group of cut flowers of bedding Pelargoniums. To each group a special certificate was awarded. From Mr. Aslett, gardener to C. Butler, Esq., of Hatfield, came a good-sized and well-grown plant of *Impatiens Jerdonei*, a plant seldom seen now-a-days, though well worthy of cultivation. From Mr. Green, gardener to W. Wilson Saunders, Esq., came *Odontoglossum Alexandre*, var. *Bowmani*, with six handsome fully expanded flowers, and examples of *Vallota purpurea major* and *V. eximia*, the flowers of the last-named being of a fine round shape, and the truss much larger, and quite distinct from the foregoing.

An interesting lot of plants was furnished by Messrs. Carter & Co., of Holborn, consisting of two triangular-shaped baskets, the one filled with *Echeveria metallica*, having a carpet of *Sedum glaucum*; the other filled with *Echeveria sanguinea*, carpeted with *Antennaria tomentosa*. There were also two circular baskets, one filled with the dwarf double golden French Marigold, edged with *Alternanthera spathulata*; the other with *Amaranthus tricolor Gordonii*, var. *pumila*, a compact-growing kind, with bright reddish foliage, broadly edged with claret, in the way of *A. elegantissimus*; also capital and well-grown specimens of the two new Ivy-leaved Pelargoniums, *L. Elegante* and *Duke of Edinburgh*. A special certificate was awarded to the group.

From Mr. John Coomber, gardener to Col. Wilkinson, Highgate, came plants of Variegated Zonal Pelargonium, Mrs. Wilkinson, a bright-looking variety with a regular edging of creamy white, and regular narrow zone of deep pink; it promises to make an effective bedder.

A collection of *Odontoglossum grande* was also furnished from the gardens of the Society.

Dallias and *Verbenas* were plentiful, the former bearing traces of being out of condition. A first-class certificate was awarded to Mr. George Rawlings, Romford, for King of Primroses, a very pleasing flower of a soft primrose hue, of good substance, full high centre, and outline. Second-class certificates were awarded to Mr. C. Turner for Queen of Beauty, blush tipped with magenta, a very pleasing and taking flower, but wanting outline and depth; and to Louisa Burgess, a Fancy flower of a salmon buff ground, striped and flaked with crimson, good petals and outline, but somewhat flat. Mr. Turner also had twelve fine and finished blooms of Unique, which received a first-class certificate at the last meeting of the Committee; Firefly, bright orange scarlet, a hue of colour much wanted, but the flowers coarse and thin; Lady Dunmore, a Fancy, orange ground tipped white, and slightly flaked with crimson; Eclipse, shaded puce, good form and substance; Countess (Fellowes), pale ground, heavily tipped with magenta; Formosa (Fellowes), peach blush, a pleasing flower of passing outline; Magdala (Fellowes), yellow ground, shaded on the edge with rosy fawn, and flaked with crimson; and six blooms of Polly Perkins, a Fancy flower, awarded a second-class certificate at the last meeting of the Committee. Mr. Rawlings also had Monarch, one bloom a rich dark shaded but undersized flower; the others tipped red and white on the dark ground; Goldfinch, pale yellow, tipped with lake; two fine blooms of Indian Chief, awarded a first-class certificate at the last meeting of the Committee; and some blooms of a crimson bedding kind of a dullish hue, of good shape, but small in

size. Mr. G. Wheeler, Warminster, had Lord Heytesbury, salmon brick red; and Mr. Keynes, Salisbury, had One in the Ring, pale ground, edged with rosy purple, very promising; one of the blooms was of fine shape and substance; Annie Neville, cream white; Lady Alderson, a Fancy, bright crimson scarlet, tipped with white; and Miss Margaret Dombain, yellow ground, tipped with pale rose.

First-class certificates were awarded to Mr. C. J. Perry, Castle Bromwich, for the following *Verbenas*:—Perfection, silken pale pink, the pip large and of very fine shape; Model, salmon pink, with large deep rose centre, fine shape, and large size; and Wonder, pale pink with rosy purple eye, fine shape and good truss. The same award was made to Mr. Eckford, of Coleshill, for Anna Keynes, a very fine and distinct variety, of a dark crimson purple hue, very fine pip and truss; and a second-class certificate was given for Lotty Eckford, brilliant plum colour, with small lemon eye, very novel and bright. Several other seedlings were shown but not in good condition, the cold weather having evidently affected them injuriously.

GENERAL MEETING.—J. Russell Reeves, Esq., F.R.S., in the chair. The business was chiefly confined to the election of three new Fellows, and the announcement of the Committee awards. The next meeting will be held October 6th, when prizes for edible Fungi will be competed for.

THE ORANGEFIELD TOMATO AND ITS CULTIVATION.

AFTER one season's experience with this Tomato, I am of opinion that it is an introduction of real worth. Its chief qualities consist in its being early and dwarf, very prolific, and that it bears forcing well. With regard to the quality and size of its fruit it is, perhaps, not preferable to older varieties, the best of which is yet the old Common Red; but for pot cultivation it is far superior to any variety I am acquainted with. One plant well grown in an 8-inch pot will bring to perfection two dozen fair-sized fruit, and it does not grow more than 18 inches high. Pot plants have an excellent and very ornamental effect in forcing houses, or arranged along each side of the pathway among fruit trees in orchard houses.

Though the Orangefield Tomato is so dwarf, and its fruit produced almost at one time, it retains the property which the older varieties possess of ripening the fruit by degrees, thereby affording daily gatherings. Amateurs and others who have a limited wall space will find this Tomato especially valuable, for it produces and ripens its fruit well when planted out in a sunny border, each plant about the same distance apart as one would plant Brussels Sprouts. They must be trained to a stout stake on account of the heavy fruit, but the stake need not be more than 2 feet out of the ground; and if well planted in a deep, rich, and rather heavy soil they will produce from the bottom of the stake to the top, and have an appearance not unlike that of a rope of Onions.

The fruit must be thinned out when about to swell off, the quantity left being regulated according to the vigour of the plant; at the same time apply a mulching of 4 inches in depth of rotten manure. The Tomato being a gross feeder, frequent applications of liquid manure will much improve the size of the fruit, and increase the quantity of pulpy matter to be extracted for making either sauce or jam.

The treatment which I have described is applicable to the scarcer-growing sorts, with just this addition—they require nailing and frequent thinnings of the shoots, while those that are retained must be pinched just beyond the clusters of bloom. With the exception of a gross shoot or two, the Orangefield Tomato makes no more wood than it requires.

With regard to sowing, my advice is to sow in pots early in March, and encourage the growth of the plants so as to have them planted out in the first week in May, and get the bulk of the fruit ripened by September. After that time the weather is often unfavourable to the ripening of the Tomato, and much fine fruit is spoiled in consequence.—THOMAS RECORD, Lillesden Gardens, Hawkhurst.

PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

SPIRÆA PALMATA (Palmate-leaved Spiræa). *Nat. ord.*, Rosaceæ. *Lin.*, *Leosandria* *Pentagynia*.—Introduced by Messrs. Noble, of Bagshot. Stems, branches, and flowers crimson. A beautiful plant. Native of Japan.—(*Bot. Mag.*, t. 5726.)

MYRICIA NAGI (Yangmae Fruit of China—Yamamo-moki of Japan). *Nat. ord.*, Myricaceæ. *Lin.*, *Monocia* *Trioctandria*.

—Cultivated in China and Japan for its sub-acid fruit, eaten either raw or cooked. Berries blood-coloured.—(*Ibid.*, t. 5727.)

AERIDES MITRATUM (Mitre-spurred Aerides). *Nat. ord.*, Orchidaceae. *Lim.*, Gynandria Monandria.—Native of Moulmein. Flowers white and purple.—(*Ibid.*, t. 5728.)

SARCOCAULON BURMANNI (Burmann's Sarcocaulon). *Nat. ord.*, Geraniaceae. *Lim.*, Pentandria Pentagynia.—Native of South Africa. Flowers white, plaited. Its stem is woody and resinous, and its branches prickly.—(*Ibid.*, t. 5729.)

LEAVENWORTHIA AUREA (Golden Leavenworthia). *Nat. ord.*, Cruciferae. *Lim.*, Tetradynamia Siliquosa.—Native of the Southern States of North America. An annual, introduced by Mr. Thompson, of the Ipswich Nurseries. Flower pink, and golden-edged.—(*Ibid.*, t. 5730.)

EPIDENDRUM PANICULATUM (Panicled Epidendrum). *Nat. ord.*, Orchidaceae. *Lim.*, Gynandria Monandria.—Native of Peru, and Bolivia, at 7000 to 8000 feet elevation. Flowers lilac, edged with pink, and these being fragrant, it is a great acquisition to our cool-house Orchids.—(*Ibid.*, t. 5731.)

LASIANDRA MACRANTHA.—"It is a grand plant, the blossoms being no less remarkable for their size than for their depth and brilliancy of colouring; but what is most remarkable of all is, that these monster blossoms are produced abundantly on the tiniest plants, while in its more developed state it forms a freely branching slender shrub of moderate size, the beauty and profusion of whose flowers will render it a noble acquisition for our flower shows, no less than for our warm conservatories."

"The plant was first made known by Dr. Seemann, who published a figure (not, however, giving the blooms of the size they have since attained), in his 'Journal of Botany' for 1861. Dr. Hooker has just published a figure in the 'Botanical Magazine,' under the name of *Pleroma macrantha*, the genus *Lasianandra* being by him merged in *Pleroma*."

"We are indebted to M. Linden for the introduction of this fine *Melastomad*, it having been sent by his collector, Libon, from the province of St. Catherine, in Brazil. M. Linden first flowered it in 1861, and it has since been produced at several of our London shows during the present year, little plants of 4 or 5 inches high bearing six or seven flowers and buds. The elegantly-shaped oblong-ovate acuminate leaves, with their deep green rugose hairy surface, set off to great advantage the large smooth-petaled saucer-shaped intense violet purple blossoms."

"As a stove plant it is of very easy culture, requiring to be treated in the same manner as *Pleroma elegans*, and while it resembles the latter in general features, it quite eclipses it in the magnitude of its flowers."—(*Florist and Pomologist*, N.S., i. 193.)

NOTES AND GLEANINGS.

A CORRESPONDENT, "F.G.," has sent us a report of the annual dinner given by the Lord Mayor to the Fruiterers' Company. On the 10th inst., he thus entertained the Master, Wardens, and the rest of the governing body of the Fruiterers' Company, at the Mansion House. "From time immemorial the Guild of Fruiterers has been accustomed to present annually to the Lord Mayor and Lady Mayoress for the time being, gifts of choice fruits of great variety, and to attend through their representatives, the Master and Wardens, at the official residence of the Chief Magistrate of the city for that purpose in autumn. The fruit is always neatly packed in clean white baskets, and covered with white napkins, and formerly it used to be borne there by a file of men servants of the Company, preceded by their beadle carrying his mace. On its reaching the Mansion House the fruit is uncovered and arranged in the saloon, and the Master of the Company usually accompanies the gift with a complimentary address to the Lord Mayor and Lady Mayoress. The ceremony concludes with an invitation to the Master and Wardens to dine there on a day named. The dinner on the present occasion was served in the Long Parlour, and covers were laid for nearly fifty guests." Our correspondent proceeds to ask whether this presentation of fruit and the convivial return are the entire duties devolving upon "the Master, Wardens, and the rest of the governing body of the Fruiterers' Company?" We acknowledge our inability to answer the query; but if the Company's Clerk, Mr. O. C. T. Eagleton, 84, Newgate Street, were applied to, he might afford some relative information. Stow, in his Chronicle, says that the Fruiterers are a very ancient brotherhood, but were first incorporated in the third year of the reign of James I.—that is, in 1605. We published in our second volume a copy of the armorial bearing

of the Company—Azure, Adam and Eve, one on each side the forbidden Apple tree, and the serpent twined round its stem. The Company now have no Hall, but when Slow wrote they had one in Worcester House, Worcester Place, in the Ward of Vintry. In 1735, they met in the Parish Clerk's Hall, in Wood Street. Seymour states that the Company consists of a Master, two Wardens, seventeen Assistants, and thirty-nine Liverymen. Noorthonek says the Livery fine is £5. Like most of the other Livery Companies its "occupation's gone." We suppose its sources of income are not. What are they? The only Companies having an efficient control over the trades they were founded to benefit, are the Goldsmiths and the Apothecaries.

—MR. VAN DER SCHELDEN, of Ghent, has discovered that the Hop contains a first-class textile material, and has invented a process by which the fibres of the vine can be used for cloth without in the least interfering with the crop of Hops. The following is said to be Mr. Van der Schelden's process of separating the fibres:—When the Hop blossoms have been gathered, the stems are cut, put up in packets, and steeped like hemp. This maceration is the most delicate process, since if it be not made with all due precision, it is very difficult to separate the threads of the bark from the woody substance. When the stalks have been well steeped they are dried in the sunshine, beaten like hemp with a beetle, and then the threads come off easily. These are carded and worked by the ordinary process, and a very strong cloth is obtained. The thickest stalks also yield the material for several kinds of rope.

POMOLOGICAL GLEANINGS.

A SEEDLING NECTARINE marked S. 238 has been received from Mr. Rivers, with the following note:—"The origin of the seedling Nectarine is unknown, but supposed to be from Victoria. It is remarkable for its marvellous richness. The fruit was produced on a tree three years old growing in a small pot." There is no doubt that this Nectarine has the Stanwick "blood" in it, and the conjecture that it may be from Victoria is not very wide of the mark. The fruit is medium-sized, and of an uniform pale yellow with a tinge of green in it; and the flesh is very melting, juicy, and richly flavoured.

—WE received at the same time two fruits of Prince of Wales Nectarine, grown against a brick wall, protected by Dr. NEWINGTON'S GLASS SCREENS; and the result is that the ripening has been hastened from ten to twelve days, and though protected in this way, the tree is perfectly free from red spider, owing to its free exposure to the rain and dew. This simple and cheap invention seems to give a healthy ripening climate, and will prove very valuable.

—REV. W. KINGSLY writes: "THE SUSQUEHANNA PEACH went to the flower show at Thirsk. One weighed well over the pound, and was 12½ inches in girth. I gave it away, and it was not eaten for nearly a week, and was then said to be excellent. The other big fellow we ate ourselves, and it was better than Exquisite, which grew in the adjacent pot. Rivers's Princess of Wales ran up to three-quarters of a pound on a heavily-cropped tree, and was grand in flavour, and few fell below 8 ozs. The pierced pots have proved their value this dry season, as they allowed the water to spread all round. I shall soon be taking them up, and then we shall see how the roots have fared."

—BUDDEN PEACHES, no doubt, as a rule make better trees than those grafted; but does it not, therefore, stand to reason that the common way of grafting has something wrong in it? I believe you will find in all cases of PEACH TREES GRAFTED by the ordinary process, the bark of the scion becomes hard to such a degree as to prevent good early growth, and so the check to the roots ruins the health of the tree; yet I possess grafted trees more vigorous than any others where attention was paid to this matter. In all cases of grafting I insert the scion, so as to have a bud close above the stock, and two beyond it if I can; these three buds are kept clear from the clay or grafting wax, and the shoot from the bud just above the stock is made the leader, the scion being cut off closely above it after the tree has plenty of leaves on it to keep the roots in health. In this way there is very little difference in appearance after a year between the budded and grafted tree; but the three eyes in the grafted tree work the roots better at the first start than the single eye from a bud, unless the same attention is paid to keeping an eye or two of the stock working for a time, and in

that case the leader does not get as much strength as in the case of the graft.—W. K.

— Mr. RIVERS writes: "ALBERT VICTOR NECTARINE has a curious history, showing what perseverance will do. Some twenty or more years since I found on a wall at Culford Hall, near Bury St. Edmunds, a 'Late Melting Nectarine,' sent from Lee's under that name, which ripened in October. I thought it was the Peterborough, but it seemed larger, it was at any rate of the same race. When orchard houses came in I commenced to raise seedlings from it, they all proved late but not large, and were not first-rate. I kept on *breeding in continuation* (mind, this is my term, and it should be adopted)—i.e., sowing the stones of each generation. No good move was made till, I think, the fourth generation, in the ALBERT VICTOR NECTARINE, which is a superb fruit."

— THE NECTARINE PEACH was noticed for the first time in the last edition of the "Gardeners' Year-Book." After another

year's trial we find that it retains the great richness of flavour which we observed in it last year. The fruit is large, and is remarkable for being terminated by a nipple, like Téton de Venns and A Bee. There is rather more down on the skin than we observed last year, when it had barely enough to distinguish it from a Nectarine. The skin is yellow, and with a bright mottled red on the side next the sun; the suture well defined, particularly near the nipple. The flesh is semi-transparent as is the case with almost all Mr. Rivers's seedlings, and with a brilliant red stain round the stone, from which it separates, leaving some strings behind it. It is melting, very richly flavoured, and with a fine racy smack. The stone has a tendency to split, and the kernel has a very mild bitter taste. It ripens in the middle of September. Flowers large. Glands kidney-shaped. This was raised from a Dutch Nectarine called Grand Noir.

— The extraordinary summer we have lately experienced has had its effect in developing some characters of fruits with which we have been hitherto unacquainted. An instance of this we have found in the Pear Doyenné Bonssoch, which in ordinary seasons requires to be eaten as soon as it ripens, otherwise it speedily becomes what is termed "sleepy." This year, notwithstanding it has been "dead ripe" on the tree, it has, after being gathered, kept for several days in a condition of soundness and of flavour rarely met with.

ECONOMY IN COMMERCIAL PLANT HOUSES.

ECONOMY OF CONSTRUCTION.—In regard to the walls of the plant house, the most economical are those constructed of wood. Procure good Cedar, Chestnut, or even Oak posts of the required length, plant them solidly in the ground, as in making a hoard fence; cut them off to the required height, and level by a chalk line and spirit level; nail on the top of them flatwise, and horizontally projecting about 1½ inch beyond the front of the posts, a piece of 2 inches by 4 Hemlock or White

Pine scantling; and within about a foot of the ground, saw and mortise out notches in the front of the posts about 2 inches wide and 1½ inch deep, and nail in them, edgewise, a piece of 2 by 3 scantling. Then on these two pieces of scantling nail vertically or up and down, 1½-inch second common White Pine boards, ploughed and grooved, and well seasoned and dried in the sun. The boards should be bought of 16-foot lengths, so that they may be cut up more economically. If the path to the house is dug 2½ feet below ground, the front wall or side of the house need not be more than 3 feet 1 or 2 inches high, which will enable you to cut five lengths out of a 16-foot board, or if the house is intended for small plants 2 feet 7 inches high, or six lengths.

If it is thought too expensive to have the boards ploughed and grooved they can be nailed on and left until they are thoroughly shrunk in the sun, and then nail plastering laths over the joints; the gable end walls can be built on the same principle, if the house is low, but if a high one they had better be regularly frame-morticed and tenoned.

If the ground on which the house is built is uneven, the boards in the side walls should be cut of one uniform length, and the earth banked-up to them. This saves board and makes the house look better. If the house is on the fixed-roof principle—that is, with permanent sash-bars instead of moveable sashes, there should be nailed in a slanting position on the upper 2 by 4 scantling, a board about 8 inches wide.

If a more durable house is required, or in cities where wooden buildings are prohibited, stone or brick must be substituted for wood. In all cases the foundation walls below the surface should be of stone, as brick under ground soon becomes soft. If stone is plentiful and cheap, the walls may be built 16 inches thick, with foundations 18 inches thick. If brick is used, a 9-inch hollow wall is the cheapest, driest, and warmest. I am surprised that houses of this kind are not more frequently built. There is no difficulty in building them even by a brick-layer who has never seen one. On the solid stone or brick foundation, about 12 inches thick, lay two courses of brick on edge, so that the wall will measure 9 inches thick, with binders on edge between each, as shown in the annexed (fig. 1), a being the brick-on-edge, and b, the binders.

Fig. 1.

Very good specimens of this kind of building can be seen in this city, built some twenty-five years since. They consist of two extensive greenhouses and a one-storey dwelling-house, and they are at this time as strong and substantial as when first erected. Sashes or windows are seldom, if ever, introduced in the front of commercial greenhouses, as they add to the expense and make the houses colder; but in houses on the fixed-roof principle, ventilators of such board working on hinges are frequently introduced at short distances along the front immediately under the plate or top scantling.

Having thus briefly described the construction of the end and side walls of the house, we come next to consider the construction of the roof, including the glazing.

The fixed roof is the most economical and expeditious in construction, and if carefully glazed, the warmest and driest. This mode of building is now so common that it is scarcely necessary to describe it. Take 1½-inch, or better still, 2-inch second common White Pine boards of the required length—say 10, 12, or 16 feet long. Send them to a sawing and planing mill and have them first planed, then ripped up into strips of 2½ to 3 inches in width, then rebated so that the glass will have a bearing of not less than one-quarter nor more than half an inch on each side. These sash-bars should be securely nailed or screwed at the upper end, to the ridge pole (if a double-pitch roofed house), or to the wall-plate if a lean-to house, and also to 2 by 3 purlins running lengthwise of the house, supported every 6 feet by pieces of 3 by 4 scantling. If the sash-bars are 10 or 12 feet long, one purlin will be sufficient, but if from 16 to 20 feet long, two will be required. These purlins are not only necessary for strength, but also to prevent the sash-bars from warping in the sun, which would cause

leakage, and in some cases would allow the glass to fall out. Although a fixed roof is the warmest, driest, and cheapest, yet it is frequently the case that the nurseryman is compelled by various reasons to use moveable sashes, as, for instance, when the ground is rented on a short lease and frequent removals are the consequence, or when plants are grown in the open ground inside the house, instead of in pots, and the removal of the sashes during the summer is necessary.

Moveable sashes as usually made, are expensive on account of the great amount of manual labour expended on them, but I have recently had made, principally by machinery, a large number of greenhouse and hotbed sashes that I have found sufficiently strong, and that cost but little more than a fixed

thickness (say half an inch), than the other sash-bars, and should be perfectly plain without any rebate. This allows the glass, when the sash is glazed, to project over the bar *a*, so that the water runs off without obstruction. If the sashes are intended for hotbeds, the side bars should extend 5 or 6 inches beyond the top and bottom bars. These ends are convenient to handle them by, and also serve to strengthen them. If the sashes are over 6 feet long, they should be braced across the middle with an iron brace one-eighth of an inch thick, or a wooden one half an inch thick.

The great saving in these sashes is in the labour. The ordinary carpenter cannot generally make more than three, or at most four, common hand-made sashes in a day; whereas, I have had fourteen, and sometimes more, of the above-described sashes made in the same time. Indeed, it does not require a carpenter at all to put them together. Any person accustomed to the use of the saw and chisel can make them. Some ten or fifteen of the bars as they come from the planing mill can be laid side by side on a work bench or table, and all of them marked out by a standard measure and a square, and then all of them can be sawed to the proper lengths at once.

We next come to the glazing of the roof. Putty has been pretty generally discarded in glazing the roofs of greenhouses, except for bedding the glass in, and this is necessary in order to exclude the cold air and to prevent leakage. In glazing, the first operation is to take soft putty, and with a glazing knife or your thumb and forefinger, coat the rebate with putty to the depth of one-sixteenth of an inch, or the thickness of the glass used. Then, commencing at the bottom of the sash-bar, put in a pane of glass with the rounded-side uppermost. This is important, as nearly all common window glass has a curve in it, and by keeping this curve always uppermost, the glass fits closer, and more effectually excludes the air and moisture. When the pane is in its place, press it down firmly at its upper end until you feel it touch the wood of the sash-bar. Then secure it in its place by half-inch cut sprigs as follows:—One on each side at bottom, to keep the glass from slipping down, and one on each side, within quarter of an inch of the top of the glass, to keep it in its place, and also to keep the pane above it from slipping down.—(Read before the Pennsylvania Horticultural Society, by Ex-President D. Rodney King.)

WORK FOR THE WEEK.

KITCHEN GARDEN.

roof. Fig. 2, is a section of the greenhouse sash. *a* and *b* represent the three outer sash-bars—viz., the two sides and top, which can be either 2 or 3 inches wide, but I have found for 8-foot sashes 2 inches sufficiently strong and stiff. They should be of good, clean, second, common 2-inch White Pine, sawed, planed, and rebated by machinery on one side only, the rebates a quarter of an inch wide and half an inch deep. The middle sash-bar, *c*, should be made of the same stuff, 2 inches wide, and rebated on each side, a quarter of an inch wide and half an inch deep. The length of the sash should, if possible, be regulated by the length of the plank, so as to avoid waste. If 12 feet long, the sash-bars can be nearly 6 feet long; if 16 feet long, 8 feet, and so on.

If the sashes are intended for a greenhouse, where they are not often moved, it will answer to put them together with three ten-penny nails at each corner, as shown at *e*; but if for hotbed sashes, screws should be used. Corner pieces of hoop iron, punched by a blacksmith (as shown at *f*), and put on with large-sized lath nails, serve to stiffen the joint and prevent the nails from drawing; but this is not absolutely necessary.

The upper and lower cross-bar of the sash *b*, should be notched-in, as at *h*, the depth of the rebate, to receive the sash-bar *c*, and the side or outer-bar *a*, should be notched-in, as at *i*, for the same depth. This not only is necessary in

Cabbage plants should be well earthed-up, and the soil kept loose between the rows while they are young. *Cauliflowers*, those who preferred August to September for sowing may now plant out the young plants where they are to remain and receive the protection of hand-lights; these should not be put on until absolutely necessary. *Endive* and *Lettuce*, some of each of these should be tied up for blanching when they are in a fit state and dry. *Capsicums* and *Tomatoes*, of which very little hopes were entertained early in the season, have made rapid progress since the middle of July, and will yield a fair crop after all. *Beets* will now be springing up in abundance from seeds carried into the garden, or shed in it, and this is the stage at which they are most easily destroyed. *Pot* and *Sweet Herbs*, this is a very good time to break up old beds of these, and plant young offsets in a bed or border. Any work of this kind, which can be done in the autumn, should never be put off till the spring. A row of *Chives* is useful in any garden; they may be divided and planted as an edging. Old *Camomile* beds, and many other things, may be renewed. *Water Cresses*, try a bed on a north border in the kitchen garden. They may be planted for weeks yet, but the sooner they are put in now the less likely they are to be thrown out of the ground by frost.

FRUIT GARDEN.

In consequence of the fine summer weather we have had this season, the growth of all trees and bushes is in a fair way of being well ripened, affording a good prospect of an excellent crop next season. Notwithstanding the repeated observations respecting the impropriety of cutting off the leaves of *Strawberry* plants, upon the proper development and full exposure of which the maturation of the buds for next season depends, the practice is still extensively adopted, and it is not unusual to meet with individuals who proudly contrast the neat appearance of their beds with the somewhat rough aspect of those where only the runners have been removed, the smallest buds

Fig. 2.

Fig. 3.

order to bring the rebates together, but adds greatly to the strength and stiffness of the sash.

The lower cross-bar, as shown at *a*, fig. 3, should be of less

singled out, and full exposure given to those remaining. The treatment of Strawberries, as of everything else, should be varied according to circumstances and the object aimed at. The mowing-off the leaves will succeed better in light soils and in warm situations than it will do on cold stiff soils; as in the first case the mowing will be earlier performed, and a succession of healthy leaves will be produced, but at the expense of the stored-up nourishment existing in the bud. It may also be adopted in those cases where the unworkman-like practice exists of depending chiefly on the runners of the present season. It is true that an abundance of Strawberries may be procured by such a system, but the results of our practice and observation seem to show that such fruit is not for a moment to be compared either in quantity or quality with that produced by the plants when their leaves were left uncut. Besides, this system of cutting off the leaves renders the plants very susceptible of injury from the first keen frosts. The spaces between the rows may now be slightly forked, and a little manure put on at the first opportunity.

FLOWER GARDEN.

Where extensive alterations and improvements in pleasure grounds are contemplated after this time, the sooner they are proceeded with the better. There are many advantages in commencing early. In the first place, more work can be done in a given time now that the ground is in a workable condition, than it is possible to perform after the rains of winter have set in, and not only can much more be done, but it can be performed in a much more satisfactory manner. Secondly, by commencing early, we have the choice of the nurseries for such plants as are required, and there is a better chance of the transplanted shrubs succeeding, because, if the autumn is mild, they will strike root at once, and if it is not mild they will become so firmly fixed in the ground as to receive little injury. New ground work should, if possible, be completed by Christmas, and all planting by the middle or end of November. Choice evergreens, especially if removed from nursery beds, are transplanted in April, as we have always found them succeed better then than when removed in autumn. The last, and perhaps the greatest advantage of autumn planting is, that it sets the gardener's hands at liberty for spring work, which, if anything like high keeping is desired in the grounds, is essentially necessary. Tulip seed may now be sown in shallow pans or boxes, covering it very slightly. Now is a most excellent time to take off and pot Carnation layers; and look well after wireworms in the compost. There is nothing like the grower's eye to detect these mischievous depredators. Keep Auriculas from the heavy autumnal rains, but let them have all the air possible.

GREENHOUSE AND CONSERVATORY.

Everything in the conservatory should be clean and sweet, the plants should never be crowded, therefore little air is wanted through the ventilators while the plants are at rest; indeed, letting in strong currents of air after this time does much mischief by drying the soil in the pots too much, and thus rendering large supplies of water necessary, when none at all should be wanted. Plants in sitting-rooms now require a very different treatment. Housemaids will ventilate their rooms as long and as often as they can, and make large fires in cold weather, very much to the injury of plants, which must have water freely every day, and should be changed as often as the stock will permit.

STOVE.

Plants here, and indeed all house plants, have ripened better this season than they generally do, owing to the hot clear weather in the end of spring and through the summer. This corresponds with the treatment generally recommended for some years past, which is, after vegetation has fairly begun in spring, to increase the temperature of the house, and by way of gentle forcing to assist Nature. Plants thus treated, and stove plants in particular, cannot be too cautiously watered late in the autumn. Nothing is now wanted but to keep the soil from becoming quite dry. In dull or rainy weather slight fires should be made in the forenoon, not so much for the purpose of raising the temperature as for drying the house. Allow a little ventilation, as stoves are generally too much crowded, and so damp that more or less air is always necessary to maintain a healthy atmosphere.

PITS AND FRAMES.

By the middle of September Violets should be planted out in pits within a few inches of the glass. After they are well watered lay half an inch of very dry soil over the surface,

in order to keep down the damp until the plants are firmly established and inured to confinement. Pots of Mignonette must also be protected from rain, but they should not be kept close. Heliotropes often become too strong at this time; if they are in the open air when this happens they never flower so freely in winter; a sparing allowance of water with some covering will soon check them. China Roses of all classes that have been closely pruned in August should now be encouraged in pits, and they will soon begin to bloom. Dwarf Neriums that have been hard forced to make young wood after flowering, should be hardened to stand over the winter in cold pits, merely keeping the frost from them. In about another fortnight the season for propagating will be over, therefore where sufficient stock is not already in, there is little time to lose. Plants that are standing out to be hardened should be so arranged as to be readily covered in case of frost, which may now be expected, and choice plants in beds, which it is intended to take up and pot, should also be protected during cold nights.—W. KEANE.

DOINGS OF THE LAST WEEK.

We were very busy in such a week of second summer, which presented so many varied sources of augmented interest as greatly to counterbalance all drawbacks and seeming evils.

KITCHEN GARDEN.

In this department we thinned out lots of Turnips, which we hope will yet come to something valuable in the autumn, and watered when thinned, as the ground is now becoming dry again, and would in the present weather be nearly as dry as ever but for the shorter days and the dewy nights. Watered Coleworts that we wish to succeed the Cabbages young and old. The main piece of the old Cabbages planted last autumn offers to do good service for a long time yet. Planted out a nice piece of Cabbages that had previously been pricked out, lifting the plants singly with small balls, and planting with the trowel, as then they are less likely to be cut down by grubs or other enemies; and to counteract the grubs this season, where they have troubled us much, threw some lime over the ground, and turned it over and examined it minutely before planting. Watered Cauliflowers now coming in, and planted out stout plants, hoping they will give us a return late if the weather be mild. Gave also a good watering to Celery tied up and not tied up, as even in beds it was becoming dry again, and but for the watering would have needed shading.

The Beans, Kidney and Runners, had also to be watered to keep them in good bearing, and from a piece of Dwarf Kidney Beans had every pod inclined to become old enough picked off, as one pod seedling will do more to exhaust the plant than a dozen pods rather more than half grown, and which will break as easily as a piece of thin glass. Whenever a pod will not break easily it is of little use in the kitchen, and should be cleared from the plant if continuous bearing is an object. Keeping this in view, we have frequently gathered last from our first sowing—in fact, but for allowing plants to produce seed pods, one sowing of Dwarf Kidney Beans, if well attended to, would just answer as well as several sowings, but in such a case close picking is the secret of success. Seed-saving must not be thought about, unless, indeed, a few plants are set aside for the purpose. By watering Vegetable Marrows they also continue to yield well. Our out-door Cucumbers were burnt up chiefly from want of clean water to treat the foliage to a shower bath.

Our chief drawback as to kitchen supply this autumn is the want of fine Peas, so great a treat in September and October for shooting parties. We did give our crops a watering too, but not what they wanted; but the parching heat was the great evil, and hence such things are scarce or not to be seen in this district, even in places where water was to be had. The mulching and the watering saved to us our Dwarf Kidney Beans and Runners, but they naturally stand a higher temperature than the Pea; as with us, with our little water at command, all our mulching, and even partial shading, failed to prevent the Pea coming weak and spindling, and ultimately succumbing altogether.

Celery.—Our most forward Celery is pronounced to be very good and sweet, but smaller than usual; and that is saying something, as we have given up aiming at having Celery monstrous in size, and for two reasons—first, that in such large Celery there was not a proportionate amount of material fit to send to table; and secondly, that when such large heads were

fit for use they could not be kept sound in drizzling weather, unless they were protected by a waterproof covering, as the rain, when it found its way to the heart of the plants, could not escape, but remained there, turned in time fetid, and then the heart, the valuable part of the plant, rotted and decayed, and all the labour went for nothing but a huge assemblage of outside leafstalks, of little use except for soups, if the cook could be coaxed to use them for that purpose.

Two or three inquiries have been made as to our reasons for not earthing-up early Celery by degrees, as last week we stated we had not the same objections in reference to late Celery, when the evaporation of moisture from the leaves is almost counterbalanced by the drizzling rains, the mists, and the dews of a late autumn. Our reason for not earthing-up gradually early Celery is based on the natural habitat of the plant, and what we have noticed as the results when these natural arrangements are greatly interfered with. The Celery is naturally a ditch plant, where in general the roots will have a sufficiency of moisture to meet the ample evaporation going on from the large expanded foliage. In such a position it will also receive less or more of shade. Deprive it of all shade, drain the moisture from the ditch, and then in the dry summer weather, the Celery plant, naturally a biennial, would in self-defence be forced to become an annual, and throw up its flower stalk the first instead of the second season. Under culture the same conditions will produce the same results. We generally give a little shade to early Celery by having Peas on the tops of the ridges, the Celery being planted in the bed trenches. The trench is just a makeshift for the ditch, and serves the purpose of retaining moisture better than planting on the level ground would do. In stiff ground the trenches should be shallow for late Celery to stand the winter. Now in the bit-by-bit earthing-up of Celery we do much the same thing for the plants as draining the ditch would do. We may water well before we give a little earthing-up, but if we place 2 or 3 inches of earth over the roots, and then in a week or two a few inches more, and so on, in order, as it is said, to encourage the heart to rise, we never think, or seldom, of the state of the roots, whilst the leaves are throwing off so much moisture every day, and then a great surprise is felt when the greater part of a bed bolts and throws up flower stalks, rendering the plants useless with cheese or for the salad bowl. Examine the roots, often as dry as if standing close to an oven, and the whole surprise need be a surprise no more. The roots could obtain no moisture near at hand, whilst the leaves were continually evaporating it in dry and sunny weather. The bit-by-bit earthing-up prevented all moisture reaching the roots of the ditch plant more effectually than if you had thoroughly drained the ditch, and the bolting of the Celery was the consequence of the roots being dry. Even as to the rising of the heart of the plant, that is sufficiently secured by first cleaning and then tying-up each plant rather loosely, and even the tying helps on the blanching process. If Celery is worth having, it is worth tying, as that keeps the heart leaves so nice and close.

Whilst for all early work—say heads for use in September, or earlier, and the first week of October, we object to the bit-by-bit earthing-up. We have no objection to an extra inch or two of soil over the roots, in which they may root upwards as well as downwards. In fact, after each heavy watering, we generally follow in an hour or two, sprinkling over the bed some well-broken soil from the sides, which, being dry, helps to keep the moisture about the roots, giving no free outlet to it except through the foliage. For early use, provided the plants are tied some time previously, the once earthing-up will do, if performed about three weeks before the plants are wanted; and, therefore, on the principles alluded to above, only a small piece is done at a time, for if large beds were earthed-up at once, before they were used, we would expect the roots to be dry just as in the bit-by-bit system, and then the same results would follow, in plants throwing up their flower stalks. The theory is borne out by results, as whenever we could give anything like common attention to our Celery, we never have had an early head bolted. In fact, such a thing has been unnoticed for many years. So much for our theory and practice, which we think of some importance, but others may know a still more excellent way.

And now a word as to earthing-up. In light soils, with tying previously, nothing is better than the garden soil. Many other materials are used. Mr. McDonald, of Woodstock, Ireland, uses moss, and few things could answer better. Old tan has also been used, but new tan is apt to give a taint, and if much is put on, it is also apt to heat. We have used leaves, but they,

too, are apt to heat. A correspondent last week recommended sawdust. We would only say, that used liberally at a time, it is apt to heat, and if from resinous wood, it will leave something of a taint. Sawdust from hard wood and rather old, is, therefore, best. In light soils, and in any soil for early produce, the soil will do for blanching. In heavy soils, and for winter supply, some coal ashes are a good material to place next the plant, and if scarce, enough just to go round the plant will do. A simple mode of giving this small supply is to have two semicircular pieces of tin—say 15 inches long and 6 inches at the semicircular diameter. These should be placed nearly together, so as to enclose the tied-up plant, and the ashes trundled down whilst the soil is put against the rim, and that removed as the earthing-up proceeds. Even a small quantity round the plants saves them considerably from worms and slugs. In heavy soils, even with ashes, it is not advisable to earth-up so high as in light soils; not more than about half would do, and then as the weather becomes cold, the plants could be packed close up to their stems with litter, placed rather firmly, and that will soon cake, and throw much water off. Plants so managed will stand the winter better than others if it is cold, and be little liable to damp off if the weather should be open and drizzly.

Prepared material for another Mushroom bed, and took the chance of such fine dry weather to run the Dutch hoe through all growing crops, Strawberry borders, &c.

FRUIT GARDEN.

Planted out thickly lots of *Strawberry plants* that had been previously pricked out, so that we may lift them in spring as wanted for forcing. In relation to this see previous remarks, and that all the more particularly, as an amateur was disappointed last season when he used such plants for early forcing. For early forcing the plants must be established now in pots. We recollect a great authority throwing cold water on all our gardening preparations, because from plants lifted from the open ground fine results were obtained in May and the beginning of June. Hence the folly of summer potting and autumn attendance. If the learned gentleman had tried his raised-up plants in January, we imagine where his triumphant notes would have been. Pricked out thickly a number of sorts in case they should be wanted, as even these will be good plants in spring, and when small they thrive all the better for company. We have had all our runners late this season, and some rows almost parched up are now like the grass, becoming green again. Had we waited for runners rooting in the open ground we would have been nowhere with our young plants in pots. By taking them off as soon as they showed, and pricking them out by the string in beds under protection, we soon had good plants for potting, many of which have now crammed the soil in the pots with fine roots. We do not think we ever had the plants potted more firmly, and they are all the better of it. This weather is just suitable for them, as maturing is helped as well as growth, and the latter all the more, as we can feed them with waterings containing something stronger than mere water. So far as these Strawberries in pots are concerned, we have no means wish rain to fall on them, except now and then, and if expected we strew the pots with a little soot, guano, or superphosphate. After many trials, however, we have come to the conclusion that we can do very well with our home manures without the help of artificial ones; but all plants, like animals, delight in a change, and though soot water is much relished by the Strawberry, something less nitrogenous is welcome as a change, as cow dung, sheep dung, &c.

One drawback there is in all this fine weather, reminding us of this, as respects ourselves and our doings, that we live in a world where all is not overbright, though we would often do well to look at the bright side, so as to check all the beginnings of grumbling. The drawback is, that with the exception of a few Plums, our stone wall fruit is gone. The Peaches and the Nectarines stood our first tropical summer well—not one fell, partly owing to mulching where we could not water; but even with the help of watering they could not stand the heat of this second summer. Late Peaches swelled too fast, and Nectarines swelled and shrivelled too in the heat, and the wasps coming in legions told us that we must take our share whilst a share could be had, and so but for our late orchard house we should be deficient in fruit for large desserts. These late houses will stand us in good stead, but we are gathering Walburton Admirable Peaches now, that kept us well in October last season.

Had we a continuance of such weather at this season, late orchard houses would be among the most useful and most economical structures about a garden, as fruit could be had

from them for large parties late in autumn, after the crop in the open air on the walls had ripened and been used. Who will set the example of a range of houses to have Peaches in October and Plums in November, and costing but wood and glass, or iron and glass?

We find the earlier Apples decay so soon after gathering, that we have left a number on the ground for the benefit of the wasps, as that keeps them from harder and finer fruit. We would like to defer gathering the later kinds a little longer, as they are acquiring such a fine colour in this weather. Lessened the late growths by removing and stopping, so that the sun should have freer access to fruit out of doors.

As to wasps, we are more convinced than ever that an encouragement in money payments should be given for wasps as soon as they appear in spring. Paying for nests at this season is something like trying to wash a blackamoor white. In fact, we are doubtful if we do not often make it worse for the garden. Whilst the nest or a semblance of it remains, be it in the shape of a bottle sunk in the ground with a hole at the neck open, and some tempting liquid at the bottom, the wasps have an inducement to return; but when all is gone, when once they come back to the garden they return no more. If even the nest is taken at night, numbers will be out, and if a bit is left to them they will flock to it during the day, and, as lately stated, a hand-light put on at night will catch numbers next day. In some cases we really think we fare worse after a nest has been demolished, if no modes are adopted to entice the outsiders and survivors. A cold night and a coldish rain will be our best aids in ridding us of these pests. Heaps of slaughtered ones seem to do little as yet in diminishing their numbers. When once they seize on a fruit it is best to leave it to them. Before they managed to leave nothing but the skin of a large Pear, it served as a grave for a score or two at a time, and then other wasps were more ready to come to it than to a fresh one.

ORNAMENTAL DEPARTMENT.

Here we intended saying much, but must confine ourselves to stating that cutting-making has been the chief business of the week.—R. F.

COVENT GARDEN MARKET.—SEPTEMBER 16.

THERE has been but little change in quotations since our last report. Supplies are quite sufficient for the demand.

FRUIT.

TRADE CATALOGUES RECEIVED.

J. W. Wimssett, Ashburnham Park Nursery, King's Road, Chelsea, London, S.W.—*Catalogue of Store and Greenhouse Plants, Trees, Shrubs, Bulbs, Pelargoniums, &c.*

Robert Parker, Exotic Nursery, Tooting, Surrey.—*Catalogue of Store, Greenhouse, and Hardy Plants, Hyacinths, &c.*

Hooper & Co., Central Avenue, Covent Garden Market, London, W.C.—*Autumn Supplement to General Catalogue, contain-*

ing Descriptive Lists of Dutch, Cape, and other Flowering Bulbs, &c.

TO CORRESPONDENTS.

“We request that no one will write privately to the departmental writers of the “Journal of Horticulture, Cottage Gardener, and Country Gentleman.” By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c.*, 171, Fleet Street, London, E.C.

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

NOTICE TO QUIT (*One in a Fix*).—If you are a yearly tenant the landlord must give you a notice to quit six months previously to the expiration of the current year's tenancy, and so as to expire at the same period of the year as that at which you entered upon the premises. If you entered at Lady-day the notice must be given at Michaelmas requiring you to quit next Lady-day.

SEEDLING GLADIOLUS (*J. P. Sharp*).—The flower is handsome, but many are like it, and many superior.

VALUE OF TREES (*Oakley*).—No one can possibly value trees of which he neither knows the names nor the condition.

INSTRUCTION IN GARDENING (*Flora*).—We should decidedly say although you have been more than five years in the various departments of gardens, Go to the Royal Horticultural Society's Garden at Chiswick, for a year or two, study hard, and compete for honours. A diploma of intelligence is a great advantage, if it is not trusted to and made to stand in the place of constant uninterrupted attention to all details of practice. Of course, we answer this in the hope you are able to go to the Society, as in many cases the going will involve a temporary sacrifice.

PLAN DISQUALIFIED (*H. S.*).—The design of a house and walled garden, but no gate or opening by which to gain admission, we think was properly disqualified. What would you say of the design for a house in which the architect had forgotten that an entrance door is needed?

FORMING A MUSHROOM BED (*Agaricus*).—Your proposed plan of preparing your stable dung for a Mushroom bed will answer well. Do not use it too wet, as then it will heat violently; nor too dry, as then it will impoverish the Mushroom, but in a medium state, neither wet nor dry; and be sure the heat is not too strong after spawning, never more than milkwarm.

POT-POUND MYRTLES (*Them*).—Pot the Myrtles at once, rubbing off a little of the outside of the buds, by using the fingers and a pointed stick, and thus get rid of a lot of the old soil without much injuring the roots.

ORCHARD-HOUSE PLANTING (*A Young Gardener*).—As your back wall is now planted with Peaches, &c., and you intend having Vines 5 feet apart, planted in an outside border, we do not think you will obtain good results long in the border inside the house, more especially as Vines are already planted there. Trees in pots would occupy the spaces before the Vines filled up. For your outside border, as the wall is 2 feet in height, we would remove the soil to a depth of a foot, have a foot of drainage, and fill up with loamy soil, half a ton of boiled bones, and three loads of lime rubbish. Write again if we have not met your case.

WEIGHT OF A BUNCH OF GRAPE (*C. P.*).—No general answer can be given to your query. The bunches of the numerous varieties vary in size. Speechly had a bunch of the Syrian Grape weighing 2½ lbs. A bunch of the Trebbiano has been exhibited weighing more than 12½ lbs. Bunches of the Black Hamburg should average 2 lbs.

COCOA-NUT FIRE REFUSE (*J. K.*).—If you write to Messrs. Barsham, Kingston-on-Thames, we think that they will forward what you require if the Great Eastern Railway.

FUNGUS ON PEAR LEAVES (*J. B. White*).—The large rusty-brown patches with rough papillated surface, are *Roestelia cancellata*, a parasitical fungus. They are said to be removable by dusting the leaves with flowers of sulphur, and if this is repeated in any year they reappear, they may be entirely prevented.

PEACH TREES IN POTS (*Somerset*).—It is likely that your vigorous Peach trees will have better-flavoured fruits when their growth is less luxuriant. The stock influences the scion, and the scion the stock, but there is no correct theory on the subject, as the results are not according to any rule.

GRAFTING PEACHES—MEREDITH'S ALCANTE GRAPE (*Idem*).—The best time to graft Peaches is in February and March, when in an orchard house. It is as well to have a little bit of the two-year-old wood at the bottom of the scion. Whip or side-grafting is as good as any. Budding can be done at any time, when the bark opens and good buds can be obtained, generally in July and August. Meredith's Alcantre Grape is sweet, has a fine aroma when fully ripe, and then it has a jet black colour. It requires a good heat.

PINE PIT (*Southern*).—Under the circumstances we would have preferred a lean-to roof, but have no objection to the hipped one you propose, nor to the plan of getting more room by digging out a path in front of the present wall. In either case the bed should be from 30 to 36 inches from the glass, and that will give you a criterion as to the height of the roof. This will do for good stubby plants. For large ones of the Providence kinds you will need more room. For stubby plants you must reckon from 24 to 30 inches, plant from plant; for young plants one-half or one-third of that distance. You can thus calculate the number you will want, according as you buy fruiting or merely young plants. For general culture nothing is better than the Ripley Queen, and to that may be added a few of the Smooth Antigua, the Black Jamaica, and the Providence for size.

ARRANGING A NEW GARDEN (J. R. Lloyd).—It is next to impossible to combine various modes of planting on the same ground, and yet have each of these in the highest perfection. The following remarks may be of importance to you:—1st, Your garden consists of two equal groups of five clumps each, in front of a range of houses, and banked at the ends, &c., with fine masses of *Rhododendrons*, and a wall covered with Ivy. The centre of each of these groups is a large diamond-shaped bed, and the four figures round it would be squares but for one side being broken in upon by the diamond. Nothing could be simpler, and the sharp angles of the squares and the diamond are artistic, if not picturesque. As a plain Dutch garden nothing could be more in keeping, and for a Rose garden with gravel paths, and stone, slate, or tile, or even box edgings, no plan could be more appropriate. Now, as to advising you. The two centre beds have three standard Roses each, the spaces between filled up with dwarfs, and the other four beds are of mixed herbaceous plants, and information is required as to a Rosery or grouping with flowering plants. First, we think that the centre bed would look better with five standards; if made into a Rose bed, the tallest in the centre, and four of equal size round. The others we would plant in the same way, with standards, half-standards, and dwarfs. No better arrangement could be made for a Rose garden; and if first-rate Roses are wanted, nothing else ought to grow with them, except such edgings as you have. Secondly, we would not advise you to centre each group, as now, with Roses and then plant the four larger beds with bedding plants, as the Rose centre will look poor in the autumn, when contrasted with the bedding plants. In fact, the centre would neutralise the gaiety of the other beds. Thirdly, without Roses, the two groups would look very well if filled with bedding plants. The next most effective mode would be to fill one group with Roses, with a few low plants among them, and the other group with bedding plants; and lastly, we would suggest a plan we have adopted at times with good effect. Plant from three to five standard Roses in each clump. Mutch these Roses well, plant a climber, as a *Convolvulus* or *Tropaeolum*, about 30 inches from the Rose, and then train it towards the stem and let it run over it, and in the autumn a little over the head of the Rose. These make rough pillar stand points in the beds, and then we would ring them all over with broad bands of contrasting colours. This will do away, however, with all dwarf Roses.

SELECT HARDY RHODODENDRONS AND AZALEAS (E. G. E.).—*Rhododendrons*: *Atrosanguineum*, *Barclayana*, *Blanche superbe*, *Blattenum*, *Comet*, *Hogarth*, *John Waterer*, *Lefevrenum*, *Maculatum purpureum*, *Towardi*, *Victoria*, and *William Downing*. *Azaleas*: *Amatula major*, *Calendulacea coccinea*, *Decurata*, *Prince of Wales*, *Rosea flavescens*, *Triumphans*, *Princesse d'Orange*, *Marie Dorothee*, *Etdendard*, *Pontica alba* (Thompson's), *Ne Plus Ultra*, and *Coccinea major*. The best time to plant *Rhododendrons* is during the next six weeks. The *Azaleas* should be planted as soon as the leaves begin to fall, or at the end of October and beginning of November.

RASPBERRY PLANTING (Alpha).—We grow the plants on trellises, with the canes 1 foot apart, and the rows 6 feet from each other. When the stool system is practised the plants should be 4 feet apart from row to row, and 3 feet from plant to plant. One well-rooted cane is enough to plant, and it should be cut down to 1 foot from the ground in the spring of the first year, so as to encourage suckers. No more than six canes should be left to each stool when the plants are strong enough to produce that number, which will be in the third year.

OLEANDER CULTURE (M. B.).—A compost of two-thirds loam from turves, one-third peat or leaf mould, and one-sixth sharp sand, will grow the Oleander well, good drainage being provided. It succeeds well in a greenhouse, and should have a light situation. In winter it should be kept dry at the roots, but not so dry as to affect the foliage. After growth commences in spring it cannot be too well supplied with water, and when it is in flower the pot may be set in a saucer, kept full of water until the flowering is past and a good growth made. Afterwards watering should be reduced, and the plant ought to have full exposure to the sun, and the lightest position the house affords. A moist atmosphere when the plant is making new growth will be beneficial, and so will a dry one when the wood is ripening. It is propagated by cuttings, which strike readily in a bottle of water, or in soil, the pots being plunged in a gentle hotbed of from 70° to 75°. Cuttings of the present year's growth are the best if taken off after the growth is complete, with or without a small portion of last year's wood.

COMPOST FOR VARIEGATED PELARGONIUMS (Idem).—Two-thirds sandy fibrous loam, best from turf, and the remaining third equal parts of old cow dung or very rotten hotbed manure, sandy peat or leaf mould, and silver sand. They should never be watered until the soil becomes dry, and before it is so dry as to cause the leaves to flag give a good watering sufficient to show itself at the drainage.

KEEPING PLANTS UNDER A GREENHOUSE STAGE (F. J.).—You may strike cuttings under your greenhouse stage, but it is not a good place, as the drip from the pots on the stage will probably fall on the pots or pans of cuttings, make it too damp for them, and cause them to rot or damp-off. The house being well ventilated is not conducive to the success of the cuttings, for, as a rule, they require a close, moist atmosphere. Under the stage is not a good place for wintering bedding plants; but as you say you will take care there shall be no drip, you may winter many bedding *Pelargoniums*, especially those taken up from the beds. *Liliums*, *Salvia patens*, and plants which have little or no foliage in winter, will be safely kept under the stage if the drip be reduced to a minimum.

SEEDLING ROSE (E. M.).—It is to be regretted that you did not had a few strong *Manetti* or *Briar* stocks with the seedling Moss Rose, as the plants would next year have made vigorous shoots, and these, if not pruned, would have produced flowers in the following year. Your plants being vigorous, we would not prune nor take them up and replant, but would leave them undisturbed, and allow them to take their chance of blooming. If they would not flower we would then advise your building a few stocks, and allowing the plants to grow without pruning until flowers were produced. It is probable you may flower them next year. Possibly a few buds might now take if inserted.

ARBOR-VITÆ BADLY FURNISHED WITH BRANCHES (J. T.).—The only plan will be to cut out the old or dead wood, and by tying the branches closer together, or training in some young shoots, make it more close and compact. Probably a judicious pruning would answer your purpose, but in pruning leave plenty of young wood.

WHITE JASMINE PROPAGATION (Idem).—It is propagated readily by

layering, which is a sure method, and also by cuttings of the ripened wood put in now in sandy soil in a cold frame, and kept close and shaded until rooted.

JUDGES PILFERING MELON SEED (G. H.).—It is not customary for judges to take seeds out of the prize Melons, and anyone who does so is a pilferer. If, as you say, any exhibitor has a good Melon and intends to send it out, it is a wrong infliction on him. The judges at poultry shows might as justly take the eggs laid in the exhibition pens by the hens exhibited.

CLEARING MUDDY WATER (J. T.).—Your only plan will be to have it filtered.

HEADING-BACK MANETTI STOCKS (P. J. N.).—You can cut off the head of the stock to within an inch or two of the bud, and the cuttings will answer to form stocks. They should be taken from the one-year-old wood, and be in length of 10 or 12 inches. They should be planted in November, and the heading-back need not take place till then.

IVY-LEAVED PELARGONIUM (Cathedral).—Silver Gem, with variegated foliage, has lilac rose or pink flowers, blotched in the upper petals with purplish crimson. There are several new hybrids between the Ivy-leaved and Zonal *Pelargoniums* to be sent out next year.

PRIMULAS (A. C.).—We do not know the address of the grower you name. There is but little difficulty in growing them fine if the rules often published are followed.

GENTLE'S TART APPLE (H. D.).—The reddish-fleshed Apple that so melted and gratified your palate, was probably the Golden Noble, and it deserves the name as a Kitchen Apple. The leaf you enclosed is not of the *Piptanthus*.

GOLDEN FEATHER PYRETHRUM (R. W.).—The seedling will do for bedding next summer. Directions for sowing are in our last number.

TOBACCO DRYING (Rev. W. H. F. H.).—The leaves are to be gathered when they assume a yellow tint, tied in small bunches, and hung up in some shady airy place to dry. When crisp watch for the first humid state of the atmosphere, when they will become soft, and pack them evenly in a box with the ends or butts all one way; press moderately, and a slight heat will be generated. Whilst warm take out the bunches, shake in the air to let off the heat, repack lightly, and, when thoroughly dry and cool, store tightly in a barrel, and keep there for use. The leaves which turn black and small disagreeably will not be spoiled if you dry them, but if fungus attack them they will lose their virtue.

PLANTS FOR HANGING BASKETS AND VASES (A Beginner).—We presume you wish for plants that will bear the open air in summer. The Ivy-leaved *Pelargoniums* are good, there being varieties with pink, scarlet, white, and mauve flowers, and silver and gold variegation; *Gazania splendens*, *Convolvulus mauritanicus*, *Alyssum variegatum*, *Fuchsias* in variety, *Heliotropes*, *Lobelia speciosa*, *Nierembergia gracilis*, *Petunias*, *Verbena Maconetii*, *Mandarinias*, *Lophospermum Hendersonii*, and *Tropaeolums* *Ball of Fire*, *Eclipse*, *Garibaldi*, and *Lobbiolum elegans*. These require the protection of a greenhouse in winter, and may be increased to any extent by cuttings for planting next year. Of hardy plants we may mention *Calystegia pubescens*, *Linaria cymbalaria*, *L. cymbalaria alba*, *Lithospermum fruticosum*, *Lysimachia nummularia*, *Saxifraga sarmentosa*, *S. Fortunei* variegata, *Vinca elegantissima*, and the small-leaved green and variegated Ivies.

REMOVING AND PLANTING EVERGREEN AND FOREST TREES (Idem).—As soon after this as the ground becomes moist and the shrubs have completed their growth, is the best time to move and plant evergreens. Deciduous and forest trees are best moved as soon as the leaves are falling, or have fallen.

POETING ROSES (Norice).—We advise you to shift the Roses into larger pots at once. It is now a good time to do so. They will succeed very well in the cold frame during the winter, moving them after pruning into the greenhouse, and you will have an earlier bloom.

"CUT FLOWERS, TWELVE BUNCHES, DISTINCT VARIETIES" (Ignoramus).—It is very much and very generally to be lamented that the committees of horticultural shows do not express their prize lists more clearly. We presume that the committee who offer a prize in the above words did not mean to exclude "species." We presume also that they mean each bunch to consist of one species or one variety, and not that each bunch may have several species or several varieties in it. You had better ask the Secretary what is meant. We do not think the Pampas Grass is within the intention of "cut flowers."

INSECTS ON CABBAGES (Subscriber).—They are the *Aphis raphani*. Syringing with tobacco water, or dusting with tobacco powder, are the only practicable remedies.

NAMES OF FRUITS (An Old Subscriber).—We have named those we at once recognised, but we protest against so many being sent by one inquirer. If each package which comes to us contained, as yours did, thirty-seven specimens, we should be obliged to decline naming them. 1, *Beurre de Rance*; 2, *Winter Nelis*; 3, *Beurre d'Arenberg*; 4, *Beurre de Rance*; 5, *Baronne de Mello*; 6, *Louise Bonne de Jersey*; 7, *Doyenné Gris*; 8, *Passe Colmar*; 9, *Roussé Leech*; 10, *Aston Town*; 11, *Croft Castle*; 12, *Van Mons Leon Leclerc*; 13, *Gros Roussé*; 14, *Beurre Hardy*; 15, *Van Mons Leon Leclerc*; 16, *Forelle*; 17, *Neuveau Poitevin*; 18, *Beurre de Die*; 19, *Beurre de Capiaumont*; 20, *Van Mons*; 21, *Passe Colmar*; 22, *Duchesse d'Angoulême*. (Mrs. J. Newman).—Your Apple is *Early Harvest*, an excellent early variety, which appears to do well in your northern climate, *Barnsey*. (C. P. B.).—1, *Kerry Pippin*; 2, *Court of Wick*; 3, *Autumn Pearmain*; 4, *Winter Greening*; 5, *Scarlet Nonpareil*; 6, *Fearn's Pippin*. Others not recognised. (David Williams).—1, *Parry's Pearmain*; 2, *Calville Blanché d'Ét.*; 3, *Sturmer Pippin*; 4, *Hercfordshire Pearmain*; 5, *Pearson's Plate*; 6, *Kerry Pippin*; 7, *Dutch Codlin*; 8, *Ribston Pippin*; 9, *Braddick's Nonpareil*; 10 and 11, *Tomme de Neige*; 12, *Dutch Mignonne*; 13, *Golden Winter Pearmain*; 14, *Conseiller de la Cour*; 15, *Crassane*. (R. Hammond).—1, *Flower of Kent*; 2, *Winter Greening*; 3, *Spring Grove Codlin*. (F. D.).—The berries are of the *Cornel*, *Cornus mascula*. (G. B.).—2, *Comte de Lamy*; 3, *Catillac*; 4, *Passe Colmar*; 5, *Dunmore*; 6, *Royal Dauphine*. (Old Subscriber in Yorkshire).—No. 1, *Beurre d'Amants*; 2, *Ferganotte Cadette*; 3, *Passe Colmar*. (Quack).—Pears: 1 and 7, *Beurre de Die*; 2, *Passe Colmar*; 5, *Baronne de Mello*; 8, *Catillac*; 9, *Seckle*. Apples: 10, *Reinette Blanche d'Espagne*; 11, *Nonpareil*; 12, *Manks Codlin*; 13, *Hawthornden*; 15, *Nonpareil*; 16, *Birmingham Pippin*; 17, *Trumpington*. 18, *Eucyranus latifolius*.

NAMES OF PLANTS (*An Amateur Subscriber*).—No one could identify a plant crushed as that you sent; nor can we undertake to name any of which we have not a flower. (*J. H. D.*).—*Arum maculatum*. (*W. James*).—1, 5, and 6, *Calluna vulgaris*, different coloured varieties; 2, *Erica tetralix*; 3, *E. tetralix alba*; 4, *E. cinerea*. (*G. M. C. W. Staplehurst*).—1 and 2, *Calluna vulgaris*; 3, *Erica cinerea*; 4, *Escallonia rubra*; 5, *Pentstemon* sp.; 6, *Valeraria plumbaginoides*. (*Rev. H. Sidebottom*).—*Koeleria paniculata*. (*M. A. H.*).—*Hieracium boreale*. (*Wesford Subscriber*).—Apparently a *Leptospermum*. (*T. S.*).—1, *Bartsia odontites*; 2, *Malva rotundifolia*; 3, *Euphorbia exigua*; 4, *Tamus communis*; 5, *Salsola kali*; 6, *Cakile maritima*. (*T. B. W.*).—1, *Clematis viticella*; 2, *C. vitalba*; 3, *Stipa pennata*; 4, *Agrostis*. (*P. J. N.*).—*Tropaeolum speciosum*.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the week ending September 15th.

DATE.	BAROMETER.		THERMOMETER.				Wind.	Rain in inches.	GENERAL REMARKS.
			Air.		Earth.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

THE MANCHESTER POULTRY SHOW PRIZE LIST.

It is seldom such a liberal prize list as that of the above Show is presented to exhibitors. Some of the prizes exceed even those of Birmingham, and although on the whole the Manchester Show must rank second to Birmingham, it is certainly second to no other. It is, therefore, a matter of regret that a Show of such importance should be held at a time of the year when numbers of exhibitors will be unable to avail themselves of it to any extent, owing to their Pigeons being in moult, and their chickens too young to compete with any chance of success. No doubt many fanciers will be represented, but I do not think I am exaggerating in saying, that on the 1st of October next, three-fourths of the Pigeons (adult birds), in the kingdom will be in deep moult, or not sufficiently recovered to be in a fit state to contend for the prize, or bear the journey and confinement. I believe this applies to all breeds, and especially to the larger, which, I think, are longer moulting or show the effects of it more. I have about thirty old Ponters, and I am sure not one will be fit to show in three weeks' time. Some have scarcely begun to moult, and have young ones. Some have their "crops" all covered with "stubble," and a few have just laid again, for the last time this season. If, therefore, I wish to show at Manchester I must send this year's birds, and of these only the early-hatched will be ready.

Then, as to poultry, doubtless many of the breeds which feather quickly will be in a fit state to show. But what of slow-feathering birds, such as Brahmas, Cochins, and Spanish? Hundreds of good birds, especially of the last-named breed, which will be in condition to do little at Birmingham, will have to stay away from Manchester. I know there have already been many chicken shows this season (how many *bona-fide* chickens have been shown is another question), but not of such importance, either as regards the honour or the value of the prizes.

These, at least, are my views on the subject, and if any brother fanciers are of the same opinion, I hope they will express it through the columns of this Journal, and that Mr. Jennison, who is very much to be commended for his excellent management and liberality, may be induced to hold his Show, in futuro, at least one month later.—ALFRED HEATH, *Calne*.

HOUDANS.

THE merits of Houdans as egg-producers I cannot mention with too much praise. Two first-class Houdan hens in my possession have from the time of their purchase, early in the spring, up to their moulting, laid almost invariably six eggs a-piece per week. They only once ceased laying altogether for either three or four days, after which interval they recommenced as vigorously as before.

These hens are and have been, as long as I have had them, confined to a small back yard, where the little grass that was laid down for them last winter was parched up during the

drought, consequently they have been dependant for green meat on what few lettuce and cabbage leaves I could afford to give them. Moreover, the same yard is co-tenanted by a Houdan cock, two mongrel hens for incubation, and on an average twenty chickens of various ages, all Houdans, and all healthy.

None of my Houdan hens has ever been broody. As to the fertility of Houdan eggs, the results of my own "hatchings-off," and the reports of neighbours whom I had supplied with eggs for sitting were most satisfactory. On an average ten chickens were obtained from a sitting of thirteen eggs, making allowance for mishaps of all sorts.

As to the hardiness of Houdans, my experience being very limited, I can only say that young Houdan chickens (my earliest were hatched in April), are in strength unsurpassed by any that have come under my notice. I find the cockerels as hardy as the pullets, and at present proportionably rapid in their growth; but I confess that the adult male birds that I have met with are usually much smaller, and apparently more delicate than the hens. My Houdans after continuous rain have occasionally suffered from cold, but have not hitherto manifested rumpy tendencies; indeed, I have found them remarkably free from disease of any sort.—H. S. FRASER, *Headley, Hants*.

STOKE-ON-TRENT POULTRY SHOW.

THE poultry department in this year's Show, which was held on the 9th and 10th inst., has proved the greatest success that the Staffordshire Agricultural Society has ever had. Not only were the classes, as a whole, remarkably good, but the day was also delightful, and the concourse of visitors was most satisfactory. With such splendid weather everything went off pleasantly, though the most ample provision had been made for the protection both of the visitors and poultry, in case of bad weather occurring. A very large tent was erected, exclusively for the poultry, and great attention was paid to the birds. The only arrangement worthy of mention in which we would suggest improvement, is that of the pens. The upper tier was somewhat too high to be effective; the bottom of the upper pens being 5 feet 6 inches from the ground, consequently they were not so easily inspected as they would have been if placed from 9 inches to a foot lower.

The *Game* fowls generally were good, and although a chicken show throughout, with the exception of Turkeys, it is quite time that all *Game* cockerels were dubbed, if sufficiently matured to be fit for present exhibition. The *Duckings* were remarkably good, and the *Spanish* and *Cochins* were equally worthy of praise. *Brahmas*, both Light and Dark-feathered, were unusually good, and constituted the largest number of entries in the Show. The *Hamburghs* were one of the best portions of the Show, every variety being particularly good. The Duke of Sutherland entered a collection of especially good birds. The *Duck* classes were a leading feature of the Show, and the Buenos Ayrean ducklings were evidently of superior quality to any exhibited for some time past.

As already stated, this being what is called a chicken show, almost every bird was new as to exhibition, and not a few appeared to the greatest disadvantage, from their never-ceasing efforts to escape from their pens. We would hint to owners, that the advantage is very great of accustoming chickens to temporary confinement before publicly exposing them to the terrors and annoyances of a general poultry show. A few of the specimens absolutely dash their plumage to tatters in their vain efforts to escape, whilst others become sullen and tremulous when thus confined for the first time. In fact, all

chickens intended for show should be made familiar and confiding before competition.

YOUNG BIRDS.

GAME (Black-breasted and other Reds).—First and Second, J. Platt, Swanlow, Winsford (Brown-breasted). Highly Commended, G. Swift, Fulford, Stone (Brown Red). Commended, G. Swift (Brown Red). **GAME** (Any other variety).—First, W. Dunning, Newport, Salop (Duck-wing). Second, Duke of Sutherland, Trentham.

SPANISH.—First, J. Walker, Wolverhampton. Second, W. Woolley, Bunbury, Tarporley. Highly Commended, W. Woolley; J. Smith, Keighley; H. & S. Cooper, Walsall; T. H. Jones, Fulham; J. Clews, Walsall. Commended, T. Cliff, Hailey.

DORKINGS (Coloured, except Silver-Greys).—First, Mrs. F. S. Arkwright, Etwell Hall, Derby. Second, Hon. W. H. W. Fitzwilliam, Wentworth Woodhouse. Highly Commended, Mrs. F. S. Arkwright; H. Pickles, jun., Earby, Skipton; G. Swift. Commended, Hon. W. H. W. Fitzwilliam.

DORKINGS (Silver-Grey or White).—First, Rev. E. S. Tiddeman, Brentwood. Second, Miss E. Williams, Donllys, Berriew. Highly Commended, Mrs. F. S. Arkwright. Commended, Hon. W. H. W. Fitzwilliam.

COCHIN-CHINA (Cinnamon or Buff).—First, Rev. S. C. Hamerton, Warwick. Second, W. H. Crewe, Etwell, Derby. Commended, G. Swift.

COCHIN-CHINA (Brown, Partridge-feathered, or other varieties).—First, E. Tudman, Whitechurch, Salop. Second, H. Lingwood, Backlesham, Woodbridge. Highly Commended, E. Tudman. Commended, A. O. Worthington, Newton Park, Burton-on-Trent; E. Shaw.

BRAMA POOTRA (Dark).—First, Mrs. Bailey, Longton. Second, J. Pointon, Biddulph, Congleton. Highly Commended, A. O. Worthington; Rev. E. Alder, Etwell, Derby. Commended, A. O. Worthington; E. Leech, Rochdale.

BRAMA POOTRA (Light).—First and Second, J. Pares, Postford, Guildford. Highly Commended, H. Dowsett, Pleshey, near Chelmsford. Commended, A. O. Worthington; J. Pares.

HAMBURG (Golden-pencilled).—First, H. Pickles, jun. Second, F. D. Mort, Stafford. Commended, F. D. Mort.

HAMBURG (Silver-pencilled).—First, Duke of Sutherland. Second, H. Pickles, jun. Highly Commended, Duke of Sutherland.

HAMBURG (Golden-spangled).—First, T. May, Wolverhampton. Second, T. Blakeman. Highly Commended, T. Boulton.

HAMBURG (Silver-spangled).—First and Second, Duke of Sutherland. Highly Commended, H. Pickles, jun. Commended, W. Parr.

GESE.—First, G. J. Mitchell, Newton Mount, Burton-on-Trent. Second, F. E. Richardson.

DUCK (White Aylesbury).—First and Second, E. Leech. Commended, A. O. Worthington; G. J. Mitchell.

DUCK (Rouen).—First, E. Leech. Second, J. J. Stott, Rochdale.

DUCK (Black East Indian).—First, Duke of Sutherland. Second, Rev. W. Sergeantson, Acton Burnell Rectory.

TURKEY.—First, E. Leech. Second and Highly Commended, F. E. Richardson.

EXTRA.—Highly Commended, Miss E. Williams (Black Crève-Cœur).

SINGLE COCKS.

GAME.—Prize, G. Swift (Black Red).

SPANISH.—Prize, P. H. Jones, Fulham, London.

DORKINGS.—Prize, Mrs. F. S. Arkwright. Highly Commended, Hon. W. H. W. Fitzwilliam.

COCHIN-CHINA.—Prize, G. Swift. Highly Commended, A. O. Worthington.

The Judge was Edward Hewitt, Esq., of Sparkbrook, near Birmingham.

SHOWING PAIRS OF PIGEONS.

In a clever letter written by Mr. J. Firth, of Dewsbury, which appeared in "our Journal" a short time ago, he appealed to the honesty of exhibitors of Pigeons to show fairly—that is, when a pair is to be shown, show a cock and hen; but, I regret to say, his appeal has been unheeded. I have been to most of the recent shows, and am ashamed to admit the abominable system of showing two hens or two cocks as pairs is, if anything, on the increase, and by men who really ought to set a better example to the fancy.

I have just returned from Southport Show, and I will tell you how I was served there. In the Short-faced Bald class I exhibited a pair (cock and hen); there were but four pairs there. I had the mortification to find both the first and second prizes awarded to four hens. There is no difficulty in proving this, for the exhibitor himself admitted it to me as we returned in the train from the show. I was served exactly the same at the last Birmingham Show with, I believe, the same birds, only shown in another name; anyway, I will swear to the two black hens.

Now, I ask, is this right? Are we to put up with it much longer? If so, all I can say, the legitimate fancy is at an end.

One of the cleverest judges, in my opinion, of a Pigeon (Mr. Fulton), went through the Pigeons with me at the Southport Show. We had no difficulty in discovering the birds honestly exhibited, and those which were not, and I think he will bear me out in what I am going to state. In Black Carrier hens there was an old cock shown; in Antwerps three pens were all cocks; Nuns, one pen, two hens; Barbs, one pen, two cocks; Timbits, one pen, two hens; Owls, one pen, two cocks; Trumpeters, one pen, two cocks; Short-faced Baldpates, two pens, all hens, &c. I can prove this and give the names of exhibitors

if necessary. At the last Birmingham Show prizes were awarded to no less than eight pens of Pigeons that were not pairs, as they should have been, but either two hens or two cocks.

I cannot imagine what pleasure any real fancier can have in taking a prize under such false pretences; and surely the judges should be able to discover some cases of similar imposition, and, if so, why not at once disqualify and expose the exhibitor? but I have been told judges do not like to do so for fear of giving offence, and not being invited to judge again.

I was pleased to observe in the prize lists for the coming Manchester and Birmingham shows "a caution" respecting pairs of Pigeons, which I hope all intending exhibitors will observe, as you may depend upon it I for one will be down upon any one who does not.—THOMAS H. RIDGETH, *Manchester*.

MANAGEMENT OF GUINEA FOWLS.

HAVING noticed a reply to "ANNA F." on Guinea Fowls, I add a few remarks, as I have kept them for some time. I keep two hens to one cock, and have set eggs from both, and they hatched well; it is seldom I find an added egg. The cock certainly showed a preference for one hen when first placed with them, but later in the season he is as attentive to one as the other. He will call them just the same as the domestic cock does when he finds a dainty morsel.

Cock birds may be distinguished by their arching their backs, running on their toes with a mincing gait, and they are more spiteful to other poultry than the hens. They both utter a disagreeable harsh note, but the hen alone says, "Come back."

If the eggs laid are removed daily the hens will keep to their nest, but if eggs are allowed to accumulate they will soon forsake it on the removal of the eggs. A nest egg should be kept in the nest. The eggs should be hatched under hens, in order to have the chicks as early as possible. They hatch in twenty-six days, not twenty-eight, as I have kept notes as to their time of incubation, and they are as true to their time as Turkeys.

Game hens, if small, are well adapted for the purpose. A garden is a good place for them, as they soon run about in search of food. I let mine out for a run on warm days at a fortnight or three weeks old, but they must be put into the coop before it becomes cool. For food there is nothing better than chopped egg, ale sop, bread and milk, or ground oats wetted with cold milk or water. Hot water makes them sticky. They require frequent feeding. People speak against bread, but I think it must be adulterated if it does not agree with young birds and poultry. I always use home-made bread. I should think alum must be injurious.—L. B.

BROOD IN SUPERS AND STORIFIED HIVES.

THE best mode of preventing brood in supers is by affording ample breeding space in the stock hive, and admitting the honey-gatherers of the side combs only through full-width spaces there. To restrict the communications is manifestly to retard the work, and consequently lessen the harvest.

Why exclude drones from supers? They neither lay eggs nor carry up pollen. That they are found in them in abundance is a strong proof of their utility; and if for no other purpose, their presence there must, by raising the temperature, facilitate exudation of wax, and promote the speedier production of combs—an invaluable requisite to the bee-master during the height of the honey season.

Both your correspondents "SEPER" and Mr. J. Prebble have fallen into the too common error of supposing bees require any assistance to ventilate their supers by lowering the temperature, the inverse of all good practice, and one of the stereotyped blunders of too many bee books; and all the contrivances, however ingenious to effect this purpose, are nothing more nor less than a mistake. Bees invariably and unmistakably protest against such apparatus by stopping them up, losing time and material in the operation. Instead of thwarting the instincts of my little favourites in this direction, I rather aid them by at once running a strip of gummed paper round the junction of each super added, so as to retain and economise the ascending genial warmth, and keep it up; rendering the warmth as equable as possible by wrapping up all supers, whether of glass

or wood, with either fleeces of wool or several thick plies of woollen cloth, thereby inducing bees to accept often a super and work steadily and continuously in it, while at a lower temperature such would never have been taken to.

It is mainly to the facility with which heated air ascends, and bees being naturally inclined to store honey in the upper portion of their domiciles, to which is to be ascribed the great success of the storified system, and its superiority over Nutt's or any other collateral system, now so generally admitted by all practical apianians. All stock hives should possess facilities for enlarging to a very considerable extent the entrances during the working season, and it is there only that ventilation is requisite, and the want of it in the fixed small ones of cottagers' hives, and the stifling overheating effects on the brood while built out preparatory to swarming, may, to a considerable extent, account for the prevalence of "foul brood" in such stocks, in comparison with swarms.

The great advantage of placing the empty super upon the filling one, instead of between it and the stock hive, doubted by some of your able contributors some time ago, I have had most ample opportunities of verifying in the present season with the most satisfactory results.

Acting on the principles hinted at above, I am never troubled with either brood or pollen in supers of my storified colonies, although some twelve years ago I was much annoyed with both in boxes and glasses, set over a central hole in common straw hives; and as an example of the benefits of the storifying system under judicious management, I may state that one hybrid Italian colony in Stewarton boxes has yielded me eight octagon supers of 20 lbs. each, or a harvest of 160 lbs. of honey, independently of body honey, and what is yet contained in two supers partly combed still upon it. This octagon pile, standing over 4 feet in height, when in full work, with three large entrances for the bees, was to many apianian friends the greatest marvel they had witnessed, at the same time being the most profitable stock of bees ever possessed during this, the finest season experienced by their owner, since becoming—A RENFREWSHIRE BEE-KEEPER.

THE USES OF SUPERS.

THE use and management of supers have been so often advocated and explained in "our Journal," that it might almost be deemed unnecessary to say more, were it not that there are many new bee-keepers, who, not having perused the preceding papers, may yet be unacquainted with the economy of the hive, and are therefore seeking information on the subject. As, however, the question at present is how to prevent the queen from entering supers, I will direct my attention principally to that point.

In the first place, then, I would ask bee-keepers if they have ever seen a division in the brood within the hives in spring—i.e., the queen depositing her eggs on the opposite sides of the hive? I say no; but she rather concentrates her eggs as much as possible (leaving only here and there a chance cell filled with pollen and water for the larva, and honey for the newly-hatched bees, so that they never require to visit the unoccupied part of the hive in order to obtain food), the patches of brood gradually increasing in size until they extend to the edges of the combs—the very time at which, as I stated in my former letters, swarming may be expected, and when in many cases supers are put on. I will not now repeat the directions already given, but will merely state what occurs at this period.

We may, then, suppose that the super has already been begun, and that every cell in the stock hive is occupied. The queen uneasily searching every part of the hive, and following the track of the workers into the super, will there deposit her eggs. To prevent queens passing into supers by means of gratings, however accurately they may be constructed, is as impossible as it would be to forge an iron hoop that would exactly fit every one's head, whatever size it might be. That which will prevent one queen from passing through will readily admit another; and what, after all, is the difference in size between a small queen and a heavy-laden worker? A queen, after gaining access to a super, will, if fertile, commence laying eggs, either in the centre or where the bees are most numerous, just in the same manner as in the stock hive, until she comes in contact with the elongated cells partly or wholly filled with honey, when she will again return to the stock hive, and fill up what cells have been emptied during her absence by the

hatching-out of brood. Thus it will be seen that the progress of the colony is retarded by restricting the queen to comparatively few cells, when it would be an easy matter to nadir the stock, and thus encourage breeding below, whilst insuring the purity and value of the supers, "and," I think I hear some of you exclaim, "produce a lot of worthless drone comb!" What then? Better to have it in the nadir than in the super, as would probably be the case if a nadir were not used. When a super is put on, and comb-building commenced in it before the stock hive is fully charged with brood, and whilst the queen is still in the height of her laying, the bees will not readily build drone comb; and if the weather be fine the cells will be extended and filled so rapidly, that a fine well-finished super will be the result.

Drone comb in supers is an annoyance to many, and how to avoid it is a puzzle; but if we only watch and endeavour to assist nature a little, many such difficulties may be expected to disappear.—A LANARKSHIRE BEE-KEEPER.

FAILURES IN UNITING BEES.

I BEGAN keeping bees in Woodbury ten-bar hives in June last, and stocked four in that month from straw hives by transferring bees and combs. My apiary now consists of eight hives—four ten-bar Woodburys, two small box hives, and two straw hives. The season here (Worcestershire), since the latter part of May has been exceptionally bad, and I have therefore been obliged to feed liberally, in addition to the honey the bees had collected.

Being anxious to ligurianise the Woodburys, if I can get them into a sufficiently strong state to live through the winter, I persuaded several people to let me deprive the hives of the bees they intended to take this year. The first two or three I operated upon and united were very successful, with the loss of but few of the bees. I marched the bees into an eke, or between two thick sticks placed upon a cloth, and set the Woodbury hive upon the top; but those I have done since, I have been very unfortunate with, though I have operated in exactly the same manner and under precisely the same circumstances. In one case the bees seemed to remain in a heap dead, and in another case, upon looking on the following morning at the hive I had attempted to unite, I was disappointed to find the garden round the hive strewn with half-dying bees, in the front under the alighting-board a heap, and on the floor-board inside the hive a large quantity of dead bees, also quite blocking up the entrance to the hive. I should be much obliged if you give me some information upon this subject.—E. J. C.

[Read Mr. Woodbury's articles on "Utilising and Uniting Condemned Bees," which appeared in Nos. 356, 357, 358, and 369; also that on "Uniting Bees," in page 198 of our present volume. The bees which "remained in a heap dead," had doubtless perished of suffocation after being driven; those which were strewn about the garden had been killed or wounded by the other bees. It appears somewhat doubtful whether it may be possible at all times to insure entire exemption from an occasional fatal quarrel of this kind, but the most likely mode of avoiding it seems to be that pointed out by Mr. Woodbury—viz., to subdue both parties by subjecting each to the operation of driving.]

The insect which you sent is a hornet.]

BEE IRREGULARITIES.

IF your correspondent, Mr. H. Cullen, had examined the hive referred to in page 104, he would in all probability have found two or more queens, either inside or just as likely outside the hive, in a state of incarceration; the cause of the erratic manoeuvring being that the two queens were held in confinement by their subjects. When the commotion of swarming commenced, instead of one swarm leaving, the two swarms made an attempt to leave at the same time, when the bees let go their charge, and the two queens coming in contact with each other their loss was almost certain. This was the cause of the two streams of bees; the one lot returning to find their queen, while the others were in search of her, when both lots had ultimately to return to their hive. I have seen similar cases in my own apiary, but I always found the queens locked in a deadly embrace. I may mention a case that happened a few miles from my place this summer, when two swarms issued from the same hive in one day with only two hours'

interval between them, and both are doing well.—A LANARKSHIRE BEE-KEEPER.

ARE WAXEN SHEETS USEFUL?

In reply to the inquiry of "Aris," which appeared in page 161, I beg to inform him that I consider waxen sheets of great value. For example: A swarm of bees furnished with waxen sheets sets to work at once, and twenty-four hours after being domiciled will have hundreds of eggs laid, and will in three days be as forward as one without them will be in eight or ten days. The advantages are—first, the whole of the bees get to work at once, thus economising time; second, regularity of combs; third, more weight is stored in supers in consequence of the regularity of the combs, with no narrow pieces intervening; fourth, brood is not so frequent in supers as when the bees are allowed to form crooked combs, and they take more readily to them.

This has been my experience since 1863, when I first made these sheets by the assistance of Messrs. Neighbour, and since that time hundreds of them have been sold and presented to different parties, who all speak highly of them. The only difficulty in giving them to bees is their liability to drop down, when the bees eat them through instead of building on them, but this only happens when they are made too thin. The thicker they are the better will they take the impression. The bees soon pare them down, and use up the surplus wax. To prevent them from falling, and to keep them straight, I pass two or three threads round the frame; I then tie the thread close to the bottom edge of the sheet, thus supporting it from falling should it break at the top. Sometimes I run the thread close to the sheet, passing the thread through holes in the top bar; but when the sheets are good and straight I use nothing. I hope these remarks may induce those to try them who have not before done so, and that they will be of as much service to them as they have been to—A LANARKSHIRE BEE-KEEPER.

MY BACHELOR HOUSEHOLD.

"WILTSHIRE RECTOR'S" late notes on his dogs arrested me in the middle of a letter I was writing to "our Journal" in a cross mood, on a cross subject. That letter has progressed no further, not that the crosses are altogether set aside, but possibly on such a topic "the least said is the soonest mended," and if this holds good of saying, doubly does it tell on writing. So the crosses may go, especially as a "gracious rain" is even now falling, "refreshing the weary earth." "WILTSHIRE RECTOR'S" notes have led me to imagine that my bachelor establishment might prove interesting to some of our readers—but then, alas, I have not his pen!

My establishment consisted of a housekeeper and a groom; the latter living in a cottage on the premises, both of them characters in their way, apt at using words in the wrong places, as, for instance, on my return home one day, the former told me that a gentleman had called, asking for a *prescription* for the organ! I recollect I had friends with me, and all of us had difficulty in keeping our countenances. Though with the ardour of a young professional, eager to attend to any case, I made up my mind that this was a case of *organic* disease, I found it had an annual aspect. My housekeeper loved all my pets, the dog—poor old Lufra, a black retriever—and the black cat being the chief in-door friends. The groom loved his "osses" and his wife, I hope the latter the best! He, too, was a character; under 8 stone, looked like a jockey, had once ridden a race, knew what sort of horse the Derby winner was, had seen his "pictur" on a handkerchief or in the "lustrated News." He too had been particularly careful to bring me back the "*deceit*" for some money he had taken to a horse dealer for horse hire! poor Button! those were, I am afraid, your palmy days. Button attended to the fowls—a mongrel lot—some Minorcas, one cock of this breed, the sole survivor of comb-cutting under the influence of ether, then just being introduced. In the other case the operation certainly had been painless and perfectly successful, only—when completed, the patient was dead! I had then no choice specimens, the Cochon mania was unknown, the best of my flock were two or three Silver-spangled Hamburg pullets, and I recollect well that one of these laid in December, the eggs being anxiously looked for by a poor sufferer in the village.

I wish, however, to speak chiefly of my cat and dog. Pussy was jet black, she had learnt to sit on my shoulder during

meal time, and many a mouthful on its road to my mouth was stopped by her paw and transferred to her own. Very gingerly did Pussy perform this little trick, and when she first tried the feat on a bachelor friend, great was his dismay! In due time Pussy was a happy mother, and it was now that she became an object of great interest in our little village. It was in this wise—Two of her kittens had been saved; some chickens were hatched the following day, the kittens were in a dark pantry, one of these I moved into the kitchen where it speedily commenced mewling, and very quickly Pussy came in search. Just, however, as Pussy was going to lift her baby in her mouth I substituted a chick. The imposition was undetected. Pussy seized the chick in her mouth and carried it off, I following in dismay, believing the last moments of the chick were arrived. Pussy, however, had tenderly laid the chick in her box and had curled her body round it, taking the greatest care of her new child. Again I played her the same trick, and again was her feathered child picked up and carried to her box; a third followed, and now Pussy's family consisted of her two kittens and three chickens. To the latter she speedily became very attached, would at once carry them back if removed, and never appeared to hurt them in the slightest. The third or fourth night, however, ended the career of one of the chickens, the verdict being "overlaid," responded to by a cry, doubtless, that Pussy did not understand. After this mishap Pussy was turned out at night, and only allowed to have the chickens when their cries under her maternal pressure could be heard; they were thus once and again preserved from a similar fate. In the course of a few days more they had grown beyond the possibility of such a mishap. Many were the visitors now to Pussy's "happy family;" very pretty was the sight when kittens and chickens were huddled together, prettier still when Pussy was there, and their white heads appeared from under her black fur. The chickens ran about the kitchen to feed, and returned to their "artificial mother." Of course, they thrived apace, and very ridiculous then did Pussy's efforts to carry them appear, the feathers slipping out of her mouth and affording but slight hold. By degrees they joined their out-door companions, but as the kitchen opened on to the yard they were constant visitors. Lufra, who had always been very good friends with Pussy, became greatly attached to one of the kittens which I kept; but I had better not forestall.

I have already said that Lufra was a black retriever. I bought her when scarcely full-grown. She was a very great favourite, had learnt many tricks, learnt them, I regret to say, with the use of the stick; following out the old lines—

"A woman, a dog, and a walnut tree,
The more you beat them, the better they be."

My walnut tree certainly had this prescription; it bore well, shall I say, in spite of it; for I never could understand why such treatment is good for it, neither do I believe it. It is a convenient method of gathering the fruit; I doubt if more can be said in its favour. As to the first, "man's best and most devoted helper," I confess myself at once a total disbeliever in the remedy. Certainly I have never tried it; further, I have never needed it, and must alter very considerably ere I do. But, as regards the dog, perhaps the prevailing opinion is that thrashing is good. Is it that the generally amiable and forgiving temper of the animal, which licks the hand that has just punished it, has strengthened the idea? I believe the idea is wrong. More may be done by rating and scolding a dog, and making him ashamed of himself, than by a liberal allowance of whip.

Spite of whip, Lufra and her master were the very best of friends. She learnt to retrieve fairly, being gifted with a very tender mouth, as she once brought me a book I had dropped out of my gig, carrying it by two or three of the central leaves, yet a careful examination failed to detect even the mark of a tooth on a single page! So, again, with the fowls, if I wanted one to kill, I used to point to it, and tell Lufra to bring it. She generally brought it in her mouth by its neck, but if I said, "Drop it," the fowl would run away, apparently none the worse, and without a feather being ruffled. So, again, with Pussy's kitten; this I had taught Lufra to carry when quite young, and she continued to do so when kitty was full-grown; indeed she would "fetch Pussy" at any time, unless the latter took refuge in a tree. Kitty was no weight for Lufra's strength, and the latter would jump the palings with Pussy in her mouth, and then play with her in the field as a cat would with a mouse.

I do not believe that jealousy is a plant thriving only in feminine soil, but certainly dear Lufra was jealous of her

master's love. Very much amused was "Mrs. Y. B. A. Z." in futuro, when on her first visit, as we were strolling round the garden, Lufra pushed herself between the pair, and pulled her dress, as though she could not brook a rival, even in human form! Yet of all the canine friends that have at various times responded to thy master's call, there is none whose memory is so cherished by thy mistress as thine, dear Lufra! No rival has supplanted thee in her affections! As a mistress, thou wast her first canine love. Thy place is not filled now!

At that time my long country ronds were accomplished in a gig. Button, perhaps his master as well, was proud of his "osses," for the usual pace was ten or twelve miles an hour. At first this was great fun to Lufra; but by degrees all good things, I suppose, pall on the appetite, and so did long ronds to Lufra. Now and then, at convenient distances, Lufra, like many an absconding debtor, was nowhere to be found. Of course she found her way home. A good scolding, then good beatings were tried; the habit, alas! only increased, and now she adopted the plan of coming in after my arrival, as though to avoid discovery. On one occasion, I recollect well, a friend had been my companion on the ronds, and Lufra had not arrived on our return. Some hours later I noticed her sitting in the field opposite my house, with her back turned to us; she was 200 yards off. I called her; she turned round with a scowl of defiance, and crept through the opposite hedge, neither did she come home till dark.

Amongst my patients was a family where Lufra was always most warmly welcomed. She was a most special favourite, and whenever I called, Lufra called also, and always some tit-bit was found for her. The young ladies, especially, petted her, and a frequent expression of their's, when about to take some nauseous dose, was "Oh! for a kiss of Lufra's forehead!" It so happened on a wet day that Lufra thought such petting more comfortable than the dirty roads, and called there. The young ladies knew her failing, knew too that poor Lufra would be whipped on her return, and accordingly to save her from punishment they sent her up by their servant, a blue ribbon tied round her neck, a note attached to the same. The note ran thus:—

"MY DEAR MASTER.—I am very sorry to say that when you were out this morning I somehow missed you, and, not being able to find you, looked in at Mrs. ——. As I was cold and wet they insisted on my remaining to have some refreshment for which I felt very grateful, especially as they promised to send me home. Hoping you will pardon my faults, and promising future amendment, believe me ever your loving and faithful."

And I wish I could put the rest, for the signature was a beautiful pen and ink sketch of their favourite, sitting up in a most repentant mood. Need I say that on this occasion, Lufra was not chastised? This, however, was not all—it was very strange, that whereas on most occasions Lufra would have slunk away, fearful of punishment, now she was as frolicsome and delighted as could be, dashed into my sitting-room, with her letter round her neck, saying as plainly as dog language, whether in Latin or not, could say, "It's all right this time, master." There was some mysterious chord of sympathy between the human and canine.

At night, when Lufra accompanied me, she often rode in the gig, lying on my feet, a capital foot-warmer, and no mean protector.

Ere I close my reminiscences of old Lufra, let me relate an anecdote that occurred when my home was no longer "a bachelor's establishment," but was thoroughly furnished with a gentle, loving helpmeet at its head. I have hinted that her mistress and Lufra very soon became great friends, and often went out together. On one of these occasions, a man or rather perhaps a brute in the form of a man, struck at the dog with his whip, and either with the whip or his vehicle lamed poor Lufra. Great was her mistress's grief, and fearing that walking home might injure the dog, she made an effort, I need not say vain, at carrying poor Lufra home. Lufra certainly could easily have placed her paws on her mistress's shoulders, the latter being one of those valuable commodities, made up by nature in small parcels. My readers can therefore imagine that her efforts as "a light porter" were rather ludicrous! —Y. B. A. Z.

OUR LETTER BOX.

BRAHMA POOTRA HEN'S LEGS PARALYSED (*Cestria*).—We can only advise you to give stimulants. If you consider your moultin hen worth the trouble and expense, we recommend the following treatment:—Put her in a dry place, under cover, and protected from easterly winds; let her have some hay or soft straw to roost upon. Her food should be stale

bread steeped in strong ale, and twice per day a large tablespoonful of port wine, which must be administered with a glass syringe. We once saved by this treatment a hen which was afterwards sold for £10.

LEGS OF LIGHT BRAHMA POOTRAS (*A. C. S.*).—The legs of Light Brahmas should be yellow; but as the birds become old the bright colour disappears, and is replaced by a flesh colour, except in some very choice specimens. In both sexes the legs should be heavily feathered, the plumage white, save the hackle, tail, and flights. The comb may be pea or single, but the former is certainly preferred.

VULTURE-HOCKED BRAHMA POOTRAS (*H. A.*).—The vulture hock would disqualify the cock in the opinion of some of our best judges. The hen is out of health, and will probably die if she do not alter. Try Bailey's pills. The brown patch on the cock's wing is, in almost every case, hereditary in the cocks; but such birds breed very well pencilled pullets. If we had to choose we should avoid it.

REARING YOUNG PARTRIDGES (*K. K.*).—We have nearly a score of tame Partridges in a place about 8 yards in length by 3 in width. They are more forward than any we have seen killed; the young cocks have their horse-shoes. You cannot turn them out to remain as tame birds; we should be glad to do so, but they either stray away or get killed by a cat or dog. They always disappear. If they are intended to breed on your manor, turn them out at once while they can obtain plenty of cover and food. They will be occasional visitors to their home till next pairing time, when they will disappear. We have had a single Partridge running tame with fowls in a yard, and bold enough to attack a dog; but as a rule they are not capable of tameness and attachment to the same degree as a Pheasant.

POULTRY SHOWS NEAR LONDON (*A. Young Fancier*).—We know of none except those in the list which we publish weekly. Dorking and Chelmsford seem the nearest.

FOOD DURING MOULTING (*P. S.*).—The question was answered at page 200 of our last number. We know of no practical mode of keeping flies out of a house. There is literally a plague of them in some places this year.

RED GAME BANTAMS (*Ashorum*).—You must follow the same rules in choosing your Bantams that you would in choosing full-sized birds. The cock should be snake-headed; his wings carried up, and close to his body; tail moderate, and rather drooping than otherwise. The hen should be small-headed, straight-combed, with wings carried close. She should be very dark brown, almost black, with golden hackle. Both should be hard-feathered. Last-spring chickens may be dubbed now, provided they are not in soft feather; if they are, the operation must be deferred till the feathers are hard. A curved pair of scissors is the best thing to operate with—such a pair as groomers use for clipping horses.

RABBITS AT OLDHAM SHOW.—Mr. A. H. Easton who took the two first prizes says, that he lives at Hull, and not at Whitby. The error was in the catalogue and was not ours.

MIDDLE COMB BROKEN OUT OF BAR HIVE (*R. S. K.*).—You had better invert the hive, drive out all the bees, and cut away any bits of comb which may have been made in the place of the broken one. Then insert the original comb, supporting it on either side by a few strips of suitable thickness cut from an old comb, and having covered the hive with its floor-board, turn it over into its proper position. Contrive some kind of temporary platform in front of the hive (which should be placed on the old stance with its front slightly raised), and knock out upon it the cluster of bees, which will speedily take possession of their old habitation wherein they will soon refix the loose comb.

BEES IN A HOUSE ROOF (*D. Williams*).—Some of the tiles should be removed so as to get at the combs, which should be cut out, and the bees brushed off in front of an empty hive placed in close proximity to the spot, and into which they will rapidly run for shelter. Keep a look-out so as to avoid injuring the queen, and after fitting the combs into the frames of a frame hive in the manner delineated in page 320 of our last volume, knock the cluster of bees out of their temporary domicile on the top of the bars, putting on the crown-board immediately but carefully, so as to avoid crushing many bees. This is the outline of the course to be pursued, but so many unforeseen contingencies may arise that success is only likely to be achieved by a skilled apianian.

LOOSE MOULT (*P. S.*).—This term is not in use among Canary fanciers, and those we have consulted do not know what it means.

PRESERVING TOMATOES (*W. L.*).—Gather them carefully without bruising, put them in a stone jar, and pour in strong brine to the top, putting on a light weight to keep them gently pressed down below the surface of the brine. Soak them in fresh water, and cook them in the usual way. Season to suit the taste as when fresh from the vine.

PRESERVING MUSHROOMS FOR WINTER USE.—The following is sent to us in answer to the query from "Mrs. C., of Galloway":—"Select for this purpose small mushroom buttons, and let them be gathered as freshly as possible. Cut the stems off quite close, and clean them with a bit of new flannel slightly moistened, and dipped into fine salt. Throw them, as they are done, into plenty of spring water mixed with a large spoonful of salt, but drain them from it quickly afterwards, and lay them in a soft cloth to dry, or the moisture about them will spoil them. For each quart boil together for five minutes two quarts of water with half a pound of common white salt, a small dessert-spoonful of white peppercorns, a couple of blades of mace, and a race of ginger. Take off the scum thoroughly and throw in the mushrooms, boil them gently for five minutes, then put them into well-warmed, wide-necked bottles, let them become perfectly cold, and pour in a little good salad oil on the top. Cork the bottles with new corks, and tie the bladder over these, or cover them with two separate bladders. When wanted for use, soak the mushrooms in warm water until the brine is sufficiently extracted.—R. D."

POULTRY MARKET.—SEPTEMBER 16.

The hot weather has rendered market quotations impossible. A few fresh lots make much more than their usual value, but they afford no means of arriving at an average price.

From observations taken near London during the last forty-one years, the average day temperature of the week is 65.5°; and its night temperature 43.9°. The greatest heat was 88°, on the 25th, 1832; and the lowest cold 26°, on the 26th, 1855. The greatest fall of rain was 1.68 inch.

ROSES WHERE THE SOIL AND CLIMATE ARE UNFAVOURABLE.

LAST year I was obliged, by change of residence, to invest in a new stock of Roses, and as I was rather rusty in the new varieties, I settled upon a list supplied by Mr. Radclyffe, and purchased all the varieties he mentioned, adding to them some I was familiar with myself. I am under many disadvantages as regards Rose-culture, therefore I think my experience during the season may be of use to some who are intending to purchase, this month or next. It may show those who live, as I do, in a cold north-midland county of Ireland on high plateau land, what kinds it will be their wisdom to select. If Mr. Radclyffe read this paper, and condescend to make any remarks upon it, correcting any errors I may have made in culture, I shall feel very grateful. I have derived very great benefit from his able articles of this time last year, and have endeavoured, as far as I was able from circumstances to do so, to carry out his instructions.

My garden is partly a flat, and partly a slope; the flat faces south-west, the slope north-east. I divided the one from the other by a wall of wooden boards, painted black, against which I planted Roses. I dug a very deep walk next to the Rose border, and made a second plantation on the other side of it. The Rose borders were dug out nearly 4 feet deep, and were filled with a mixture of good loam from a pasture field, hotbed manure, leaf mould, earth from old Potato ground, and a good admixture of sand. The rest of the Roses were planted in beds cut out of grass, in the north-east-facing slope. They had more manure, but less fresh earth and leaf mould than their sisters on the wall and next to it.

As the climate here is very wet, causing the frost to be particularly mischievous, I covered all the plants well with fern and stable manure during the winter. Here, I am sure, I was wrong, for the winter was excessively mild, and they did not need protection, and the covering made them push a number of weakly premature shoots. Some of these when I pruned in March I left on, and there was not a decent blossom on one of them.

At first I was inclined to disagree with Mr. Radclyffe as to the relative merits of Manetti and Briar stocks. The Briar Roses pushed earlier, and at first more vigorously than the others, which pushed mostly from the top, and exhibited long, lanky, ill-furnished stems for some time; but by the middle of June I began to alter my opinion, and I am now entirely convinced that Mr. Radclyffe is right. The Manetti-stocked Roses have distanced those on the Briar altogether, and are now (in September), giving a very fair quantity of young wood, which will bloom at the end of the month or in October.

I gave them a great quantity of water, quite as much as Mr. Radclyffe says he gave his, let it flow freely over their leaves, supplied them well with superphosphate, stirred the soil about them every second day, and up to the end of July had very little mildew indeed, though all

the gardens about were white with it. I was absent for the entire month of August, rather a wet month here; when I returned home I found a great deal of mildew and orange fungus. I have nearly got this under now, but the Roses on the north-east slope look very far from healthy. Their leaves have mostly dropped off, they are making very little blooming wood, and such blossoms as are on them are poor and stunted. Does Mr. Radclyffe think that this arises from the aspect not being sufficiently warm for them, or does he think that it would be well to dig them up, and enrich the beds?

Marchal Niel, I suspect, like Mr. Radclyffe's plant last year, had bad roots. It is on the Briar stock, and came from the nursery a nice-looking plant with one shoot about 8 inches long. It hardly grew at all till the middle of July, since which time it has made a considerable quantity of wood, but only now has it condescended to show any flower buds. It has never had either mildew or fungus on it, though the Rose next to it, *Madame Fillion*, has been bad in both these particulars. Mr. Kent described *Madame Fillion* last year as delicate in constitution. I have not found it such, but if it do not give me better flowers next year than this season I shall discard it. The blossoms opened all to one side, and were not worth looking at. I consider them rose-coloured, not salmon-coloured at all.

Rushton Radclyffe arrived a miserably small plant. At first it was very sickly, but in July it began to grow, and on the 19th of that month it had by far the most magnificent blossom for size and colour I ever saw in my life. It was enormous, quite double, beautifully shaped, and nearer the colour of the *Lobelia fulgens* than of any other flower I can think of. Afterwards it gave a few more beautiful blossoms, not equal to the one described, but very fine; it is now healthy, and has a good many buds on it.

George Prince bloomed abundantly, and has made good wood. It is a double, well filled, small Rose, of a bright cerise crimson.

Charles Wood is very valuable, the blossoms large, double, durable, of a fine bright crimson; the habit of the plant very free, and apparently an abundant autumn bloomer.

Dr. André and *Jean Rosenkrantz* are very like each other, both in blossom and foliage. The bloom of the former is grand in every respect; the foliage of the latter large, glossy, and luxuriant. They resemble each other also in producing their blooms on singularly long flower-stalks.

Lord Clyde, first-rate. The colour particularly rich, more scarlet than any other Rose, except *Rushton Radclyffe*; a good grower, and good bloomer.

Charles Lefebvre had some beautiful blossoms; and upon the whole, where they are good, it is about the best Rose out, but the blossoms seem to suffer much from the attacks of some insect (I could never find it, though I saw its traces), and the habit of the plant is very scraggy; I have have always found it to be so.

Marchal Vaillant, first-rate; shape, colour, fulness,

growth, all that can be desired. This year, however, it is not distinguishing itself as an autumn bloomer.

Mademoiselle Bonnaire was most lovely in its first blossoms. I wonder we do not hear more about this kind. The flowers are somewhat of the colour of the old Blush, and perfectly shaped. It bloomed very abundantly in June, but is in a north-east bed, and is not doing well at this period of the season.

Seur des Anges, next to the preceding, had plenty of huge buds, but not one developed into a blossom. Perhaps on a wall it might do better.

Alfred Colomb.—Glorious. Perfect in shape, colour, fulness, and everything. I lament that I have it on a Briar instead of a Manetti stock, but will have it on that this year. I think the colour is most inaccurately described in the lists as fiery red. It is exquisitely soft. The nearest approach to it is a very good high-coloured bud of Charles Lawson.

Charles Rouillard has had only one blossom. It is a well-shaped Rose, of a colour I do not much fancy. It has grown luxuriantly, making many shoots 4 feet high. It is on the Manetti stock, and has been much troubled with mildew. No signs of blossom on its tall shoots.

Leopold Premier, planted next to it, has not borne well, and its buds have never once opened.

Camille Bernardin was, I thought, in summer a much over-rated Rose. I set it down as a faded Général Jacqueminot, but it has done beautifully this month. Its blossoms have been double the size of the summer ones, and it is now covered with buds and blooms on the top of shoots 4 feet high.

Exposition de Brie.—In every respect much the same as the former Rose.

Prince de Portia.—Ditto, but brighter in colour; perhaps not quite so double.

Madame Victor Verdier.—A magnificent Rose. With me better than *Senateur Vaisse*, opens more freely, and grows far more luxuriantly.

Madame Vidot, *Madame Rivers*, and *Comtesse de Chabillant* have all done badly—poor blossoms, stunted plants. I shall try them against a wall.

Beauty of Waltham.—A valuable Rose, from its freedom of bloom and growth. Its blossoms are too loose, but it is very sweet, and blooms well in the autumn.

Prince Camille de Rohan has done badly, though it is on the Manetti, and is against the wall. Its blossoms have been starved, and ragged-looking, though with the richest treatment, and the plant looks unhealthy, although it has made some strong shoots.

Duchesse de Caylus, *François Lacharme*, and *Gabrielle de Peyronny*, all in north-east beds, have bloomed abundantly and beautifully in summer (the last a splendid, large, double Rose), and all look rather unhealthy now.

Fisher Holmes and *Professor Koch* are both far too dull in colour to please me, and they both show centres the moment they expand.

Madame Charles Wood.—A grand Rose in every way. In my present garden it has always a very curious, but very beautifully mottled, appearance. It has bloomed more freely in September than in June.

Comte Cavour and *Souvenir de William Wood* I do not like. The first is too thin and flabby, and the second has always a burnt-up look.

Souvenir de Dr. Jamain is beautiful when it first expands, much the colour of the old Tuscan; not a bit the bluish colour as described in Rose lists. It is a very free grower and autumnal flowerer.

François Arago.—The same may be said of this—a very fine, double, dark, almost plum-coloured Rose.

Pierre Notting has done splendidly. Curiously enough it never would open in the far-more favoured locality where I last resided. It has grown luxuriantly on the Manetti stock, and is now covered with buds and blooms.

I will only notice further *John Hopper*, with me perfect in every respect; and *Victor Verdier*, with a beautiful shell-like blossom, but wretchedly poor growth.

The *crème de la crème*, at least for this part of the country, I consider to be *Alfred Colomb*, *Pierre Notting*, *Gloire de Dijon*, *John Hopper*, *Maréchal Vaillant*, *Lord Clyde*, *Dr. André*, *Jean Rosenkrantz*, *Madame Victor Verdier*, *Camille Bernardin*, *Exposition de Brie*, *Charles Lefebvre*, *François Arago*, *Charles Wood*, *Rushton Radclyffe*, *Gabrielle de Peyronny*, and *Madame Charles Wood*.

My only excuse for troubling you with this paper is the hope

it may be of use to people having a bad soil and climate like myself, to whom lists from more favoured localities are comparatively of but little use. I should have been glad of such a paper myself last year from a neighbour.—Q. Q.

NOTES ON PEACH AND NECTARINE GROWING.

These are two of the most delicious fruits: they are both objects of my predilection and care; and both can with proper treatment be grown out of doors, in the south of England at least, without the aid of glass. The French are said to train their trees better, and to grow better crops out of doors than the English. This has been properly accounted for by Mr. Fleming, of Cliveden—namely, the superior French climate, and the particular devotion of the French gardener to wall-tree training. As to the French gardens, gardeners, and gardening being generally better than the English, I am informed by "D." of Deal, and others who have visited France and its nurseries and gardens, that such is not the case; on the contrary, the general gardening is slovenly, even in the vicinity of Paris. Of course, there are splendid exceptions. Of their gardening I myself have no knowledge. With regard to the management of the above fruit trees out of doors, I believe we may learn a profitable lesson from the French gardener.

As we cannot manage Peaches and Nectarines till we procure them, I will give a selection of such as I know to be good.

PEACHES.—Early York, Early Alfred, Grosse Mignonne, Royal George, Noblesse, in all respects first-rate; Chancellor, Red Magdalen, Violette Hâtive, Stirling Castle, Barrington, Ballegarde, and Princess of Wales, a splendid late Peach of great size, great beauty, and of fine flavour. If later Peaches than these are wanted, Mr. Rivers in a letter speaks in the highest terms of these—Lord Palmerston, Mr. Radclyffe, and Lady Palmerston. These three, he says, will take us into October, and as late as Peaches are good out of doors. I have others not yet proven, as Stamp-the-World, Dr. Hogg, Early Victoria, Prince of Wales, Salway, Walburton Admirable, and Alexandra Noblesse. The above have not yet fruited. For the size of the trees none have borne better crops than Stirling Castle, apparently of the Royal George race and good; and Early Alfred. The tree of the former is scarcely 18 inches high, and bore eleven Peaches, being planted about Christmas; and the latter, a beautiful and first-rate early Peach, in its second year bore seventeen fine Peaches. The tree is 28 inches high, and 42 inches wide. The largest Peach of the Princess of Wales, not yet ripe, measures every way 9½ inches.

NECTARINES.—Elruge, Violette Hâtive, Pitmaston Orange, Red Roman, Rivers's Victoria, and the White Nectarine, an excellent bearer and delicious. The following have not yet fruited:—Balgowan, Prince of Wales, Rivers's Orange, Rivers's Pine Apple; No. 12, a seedling of Mr. Rivers's; Murrey, and Rivers's Whits.

The proved and unproved Peaches and Nectarines are full of triple buds on firm, well-ripened wood. Of these I hope to speak hereafter. The reader may select with safety from those I have proved, and will find it difficult to beat such.

PLANTING.—I think that people plant, in cold soils and climates, their Peach and Nectarine trees too deeply. I found here that the trees planted in the soil produced large wood which did not ripen. I therefore last autumn moved all my trees, cut their roots much shorter, and planted them almost on the surface of the soil, placing over the roots a little soil, and on the top of that three shovelful of lime rubbish. Considering that the trees have been here only one and two years, it has answered well. I sent six fruit of Royal George and six of Noblesse to Blandford Show, and won an extra prize with the former. The trees from which both lots were gathered were planted about Christmas. Peaches from my old trees at Rushton had to succumb to them. I only allow my trees about 18 inches of border. I prefer root-pruning and feeding from "hand to mouth," to allowing the roots to ramble all over the garden. To have good wood and fruit we want plenty of fibrous network, and not huge perpendicular and horizontal roots. Of course, roots so enured require in hot dry summers good mulching and plenty of water. I think it is a good plan to annually remove trees that produce large succulent wood destitute of triple eyes, till they come into bearing. My maiden trees, bought two years ago, are now full of triple eyes on good wood. I attribute this result to removal, root-pruning, and a hot, dry summer. I expect to be able to show the champions of French

gardening next year that we are not so far behind our neighbours on the other side of the Channel.

PINCHING AND PRUNING.—There is but little necessity for a knife when pinching has been properly performed. I think many persons who prune by pinching do it too early; hence, if a wet growing time sets in, "*anticipés*," are forced out. Much depends on the character of the season. This year I stopped by pinching all my shoots, including terminals, on July 21st. It seems to have answered well. Another year it may be best to pinch later or earlier. I disbud but little. I spur some of the freshshoots, and pinch alternately to about 4 and 8 inches the side shoots. This gives two chances. I did this at Rushton, and I see by Mr. Bréhaut's excellent work that he approves of and recommends it.

If M. Grin's severe system is adopted, *anticipés* will give great trouble, especially if pinched early; and trees so served, unless root-pruned severely, will exude gum, by reason of the trees not having sufficient leaves to elaborate the sap. If I were asked to give reasons for the sad state our out-of-door Peach and Nectarine trees are in, I should say it was owing to winter injuries, too much disbudding, and neglect of the foliage at the time of expansion and during the fruiting season. Owing to protecting my trees with sheets—some fixed as a coping, and others moveable by rings on iron rods, I have had this year but little blister, which arises mainly from rupture of the tissues of the leaves in their tender state, and from injury to the main wood in winter.

NAILING AND TYING.—I use cast-iron nails, which can be easily broken off; hence no holes are left for insects to winter in; but I leave the nails in the wall for future use. I tie with bast, which is neater than shreds, and does not harbour enemies. The bast must not be tied too tightly, otherwise gum will be the result. If the sap is stopped by a tight ligature the sun will cause gum. Mr. Williams, of Woolland, near here, sent for me to see his Peaches and Nectarines trained to strained wires, as he said that he had heard that wire-trained trees were a failure. His trees were a complete success. I never saw finer specimens of the Late Admirable, wrongly tallied Millet's Mignonne, which is the same as the Royal George. What a pity that the form of the Late Admirable is spoiled by a turgid nipple with an acute point! I believe the only other Peach that has this unsightly nipple is Téton de Venus, which some have confounded with the Late Admirable. When walls are wired the wires should be strained so as to be close to the wall, as Peach and Nectarine blossoms do not like draughts of wind behind them. This is probably the cause of the failure of wire-trained trees. Where walls stand singly, an abutment should be built to stop the eddying of the wind.—W. F. RADCLIFFE, *Okeford Fitzpaine*.

(To be continued.)

WHO WAS THE FIRST IMPROVER OF THE HOLLYHOCK?

My thanks are due to "A HOLLYHOCK AMATEUR," for his statement, page 183, of Mr. Chater's first doings with the Hollyhock. No one more deserves the credit and patronage experienced than Mr. Chater, as a raiser and grower of Hollyhocks; but I would submit that "A HOLLYHOCK AMATEUR," in reviewing my errors has fallen into a still greater one—he does not distinguish between an originator and an improver. Mr. Chater in 1818 crossed his flower Napoleon with Mr. Baron's Queen, resulting in a new strain. For twenty-five or thirty years Mr. Chater had been collecting and improving, but no improvement is effected until Mr. Chater is in possession of Mr. Baron's plants, and the first improvement is through the effect of the pollen of Mr. Baron's Queen on Mr. Chater's Napoleon. In Mr. Baron's stock Mr. Chater has a new strain, the first improvement is by and through them. That is "A HOLLYHOCK AMATEUR'S" own showing.

Mr. Baron, in 1823, as is stated by "A HOLLYHOCK AMATEUR," added to his collection that of an amateur named Johnson, having at the time the "best or finest collection in the world." With those for more than twenty years Mr. Baron worked hard and perseveringly in bringing the Hollyhock up to the florist's standard of excellence. Through Mr. Glenny's recommendation Mr. Baron let out both seed and plants. His plants were distinct from those possessed by any other grower, and were eagerly sought after. Mr. Chater, Mr. Bircham, Mr. Parsons, and others, obtained the new and improved race of Hollyhocks by which they have originated varieties outstripping

all Mr. Baron's Hollyhocks, for none of his varieties is up to the present standard. All our improvements in Hollyhocks being effected through or by Mr. Baron's flowers, he and he alone, was the originator of the past and present improved race. To him, as an old florist, attaches the merit of converting a thin shapeless disk into a half globe of close thick florets, and guard petals of good proportions.

"A HOLLYHOCK AMATEUR" forgets that the Queen was a seedling of Mr. Baron's, which ought to entitle him to something more than the name of collector only; and his statement that Mr. Baron had not a white, yellow, purple or scarlet, is certainly not correct, for Mr. Bircham had from Mr. Baron's stock Purple Perfection, in purples, also Pourpre de Tyre, and yellow in Lemonade, and in Mrs. Oakes we have the salmon, said to have originated from the cross, by Mr. Chater, of his Napoleon with Mr. Baron's Queen. In like manner whites and scarlets have come from Mr. Baron's strain, independently of those in the possession of Mr. Chater. Both Mr. Bircham and Mr. Parsons had of Mr. Baron all the shades of colour alleged by "A HOLLYHOCK AMATEUR" to have been in Mr. Chater's sole possession when Mr. Baron sent out seeds and plants.

Nothing is further from my purpose than to take from the credit due to Mr. Chater, as an eminent raiser and grower of Hollyhocks; beyond that I cannot go. As to his varieties being still the best sent out, "being of better form, more substance in the petal, and more decided in colour," in justice to other raisers, as Mr. W. Paul (quite as successful in cross-breeding as Mr. Chater), Mr. Roakes, Mr. Parsons, Mr. Bircham, Mr. Parker, Mr. Gibbon, Downie & Laird, &c., I beg to differ from "A HOLLYHOCK AMATEUR'S" dictum, as the best white we have is due to Mr. W. Paul; yellow to Mr. Roake; purple to Mr. Bircham; whilst in scarlet shades, Mr. W. Paul is as rich as Mr. Chater.—G. ARREY.

VARIEGATED AND OTHER PELARGONIUMS AT CAMDEN LODGE, SISSINGHURST.

At a time when Pelargoniums of the Tricolor section form so important a feature in fashionable flower gardening, those who have the good fortune or skill to manage them will have many inquiries made of them as to how they succeeded in growing them so luxuriantly, and propagating them so abundantly. Amongst those who have accomplished both these feats in a manner which makes many of us almost envious, Mr. Potton, gardener at Camden Lodge, near Sissinghurst, is certainly one of the most successful, not, perhaps, in the raising of new varieties, but in growing established kinds with a luxuriance but rarely met with, and that, too, without apparently any other than the usual means at the disposal of most growers. One especial aid, perhaps, he may have, which every one has not, but even that is of a kind which many others possess in equal proportion, and I am far from certain whether the success attending Mr. Potton's cultivation can be traced to that source or not. Certainly it is mostly due to the care, skill, and assiduity which make everything else succeed, and as the other advantages which it may be presumed contribute to so good a result are natural advantages, some allusion to them may be briefly made before entering upon the details of the mode of cultivation adopted. A short description of the locality may, therefore, be given to show how far success in the cultivation of this interesting group of plants may be supposed to be influenced by the conditions which that presents. I will take the same leave a shrewd old farmer always took when called upon to look over a farm—to peep over the hedge into the adjoining one also, so as to convince himself that what he saw in one place was confirmed in another. In this case I will, therefore, before describing Mr. Potton's success as a Pelargonium grower, take a glance at the district, to see if some of the causes of success are not in a measure due to natural conditions assisting the skill exercised in cultivation.

The undulating district in the southern part of the county of Kent, possesses a soil and features widely different from those of the two level tracts which bound it on the north and south. Irregular eminences of no great elevation form a sort of watershed, from which the water flows in both these directions. This broken chain would seem to rise a few miles to the west of Tenterden, and continue westward considerably beyond Tunbridge Wells, and the little village of Sissinghurst is between these places. The soil, although it differs in places, is in most cases more or less impregnated with iron, and presents the

class of plants common to soils of this kind; it consequently differs from the Wealden clays that lie on the north, or the deep rich soils of Romney Marsh on the opposite side, which tradition says have been reclaimed from the sea, and which are still defended against it by high banks kept up at great expense. Occasional patches of Heath, with Fern, Broom, Furze, Foxglove, and other plants in a wild state, indicate a soil in which the Rhododendron and similar plants would do well. Such is the soil in which Mr. Potton grows his Tricolor Pelargoniums to such perfection, and as some of the readers of this Journal have soil of a similar kind, their success or otherwise, if reported, would form an interesting solution of the question—viz., What influence soil really has on the markings of this important class of plants? I am certainly of belief that it has a great influence, but I am anxious to hear the arguments on the other side.

I must add that this soil does not seem to grow Rhododendrons and similar plants so well as that of many parts of Surrey and elsewhere, the soil at Sissinghurst being modified or balanced by admixture with other ingredients, not in the black peats of Surrey, although it is well adapted for most of the purposes of husbandry, and fertile in other respects. It is neither a peat in colour nor texture, and although it possesses the necessary amount of sand to keep it open, it has by no means an undue proportion of it, while in colour it is medium. The situation of Camden Lodge presents nothing remarkable; a comfortable residence is surrounded by dressed grounds on most of its sides, and these, along with a kitchen garden and some fruit and plant houses of an ordinary kind, offer as a whole no feature worthy of special remark, but when taken in detail, and the healthy growth of many of the products is considered, one cannot but feel pleased at the skill with which everything is managed.

As a proof of the success achieved in growing and propagating choice bedding Pelargoniums at this place, I may mention that the stock of Mrs. Pollock was so large in 1865, that in the following spring it was determined to sell some, and I believe upwards of three thousand plants were disposed of at that time. This may not appear so remarkable to those who prepare for very large places, as I remember on visiting Enville, many years ago, being told that seven thousand plants of Golden Chain were turned out; but when it is considered that the place I refer to is small, and Mrs. Pollock three years ago was much more scarce than now, the numbers seem large, and I believe the plants had all been reared from a very small beginning. Other kinds are as rapidly multiplied, and on looking round one is astonished at seeing large beds of kinds which people think themselves fortunate in possessing single plants of, yet such is the case. At the same time Mr. Potton only grows really good, healthy kinds, rejecting all poor growers, unless in some special case, when they are cultivated to compare with others. In general, the majority of his plants are grown in circular and other shaped beds on the lawn, interspersed here and there with some choice shrubs or Conifers, and very often planted in the same bed with Calceolarias, Lobelias, and other plants, as will be understood by the following descriptions of some of these beds, the beds being taken promiscuously, and not as representing a series or geometrical set, as is often the case.

A large oval bed is planted thus:—*Coleus Veitchii* in a mass in the centre, Pelargonium *Perilla* in a band round the *Coleus*, Beauty of Calderdale in a band round *Perilla*, Model in a band round the preceding. Mangles's Variegated forms the edging next the grass.

The three Pelargoniums—*Perilla*, Beauty of Calderdale, and Model are all Bronze and Gold varieties of different hues, yet all robust growers, and they blended admirably. Their distinctive features are more perceptible when a number of plants are grown together, and may be described thus:—

Perilla.—Very distinct, of robust habit, and rather upright growth, with scarlet flowers. It resembles in growth and flowering the old variety called Crystal Palace Scarlet, but, of course, the markings on its foliage give it a distinction from most of the Tricolors of the Mrs. Pollock class.

Beauty of Calderdale.—This is also of robust growth, the leaves large and even fleshy, the zone a reddish brown; habit of the plant rather spreading; flowers scarlet. This is unquestionably one of the best of its class, and where it was grown presented all the sturdiness of growth that Stella usually has, with a much larger foliage.

Model.—Somewhat in the same way as *Perilla*, but dwarfer, and with salmon-coloured flowers. The ground colour and

markings of its foliage are much the same as in *Perilla*, and it is well deserving of extensive cultivation.

A circular bed of medium size has for its centre a mass of *Sophia Dumaresque* Pelargonium, and an edging of *Lobelia Paxtonii*.

Sophia Dumaresque.—A Tricolor in the way of Sunset, being paler than Mrs. Pollock; it is, however, a much better grower than Sunset, and is a deserving variety in every respect, the zone being very distinctly marked, and the whole plant more robust than many of its class.

Another circular bed has in the centre a mass of *Centaurea candidissima*; Lady Cullum Pelargonium in a broad band around the *Centaurea*; L'Elegante, a white-edged Ivy leaf Pelargonium, as an edging next the grass.

Lady Cullum is too well known to require comment. The only fault most growers find with it is its slow growth; and even here it does not go on so well as many other kinds, yet those in the bed referred to looked well, although I was told upwards of 150 cuttings had been taken off only a day or two before, and 150 cuttings from Lady Cullum are what everyone cannot obtain at one time. When well grown, this variety would be difficult to improve upon; but in too many cases we are apt to see it in a lingering, half-starved condition, when almost anything looks better.

L'Elegante.—This is the best silver-edged Ivy leaf Pelargonium I am acquainted with, and I hope to see it still further improved, as I cannot but think this class of plants has been too long neglected, for there are many positions, as vases, baskets, and other places, where they stand unrivalled. A sort with a still broader band of white marking than this would be desirable. As it is, it is far in advance of others in its class.

An oval bed is thus planted:—A mass of Pelargonium Aureum in the centre, a band of *Amaranthus melancholicus*, *Pyrethrum Golden Feather*, and *Cerastium* as an edging next the turf.

Aureum.—This is in the way of Cloth of Gold, but much better. It is interspersed, however, by Crystal Palace Gem, which will be described hereafter. Nevertheless, with some growers Aureum is the better of the two, and here it is quite as good. Its chief merit would seem to be to compete with Golden Chain, as a bright yellow leaf is its principal feature. The other plants in this bed all looked well, but they are too well known to need description.

In a circular bed we find Crystal Palace Gem Pelargonium as a mass in the centre; *Coleus Verschaffeltii* in a band next the last named, a band of Flower of Spring Pelargonium, a band of *Lobelia speciosa*, and a dwarf silver-edged Pelargonium next the grass.

Crystal Palace Gem.—Having already described Model, to which this bears some resemblance, I may add that at Camden Lodge this variety was much the finer of the two. It is, moreover, more of a Tricolor, the zone being dark red; the flowers are rose-coloured. It is well deserving the attention of all growers, as it promises to grow as fast as Tom Thumb, and possesses all the requisites of a Golden-leaved Pelargonium.

A large oval bed contains Roi d'Italie Pelargonium in a mass in the centre; Vandyke in a band next Roi d'Italie; Flower of Spring in a band; and Mrs. Pollock in two rows next the turf.

Roi d'Italie.—This well-known old kind was doing well in the position assigned it here, its rosy scarlet blooms showing to great advantage when surrounded by the fine variety adjoining it.

Vandyke.—This is somewhat like Beauty of Calderdale, and was, I believe, raised by the same grower, Mr. Wills, to whom the floral world owes so much. It may, however, be somewhat dwarfer, but is not by any means "miffy;" on the contrary, it is of good growth.

Flower of Spring and Mrs. Pollock, two good varieties, likely to be in demand for many years, and, perhaps, more often met with at the present day than any other, Stella, perhaps, excepted.

The curved ribbon border facing both sides was planted with five rows thus—namely, Meteor Pelargonium, a white-flowered variety, good; Tom Thumb, a line on each side of last named; *Lobelia speciosa* as an edging on both sides, and here it had done better than anywhere I have seen it this season. Perhaps watering had something to do with this result.

Besides the beds enumerated, there were others containing varieties scarcely less interesting, while in a wide border adjoining the kitchen garden, beds were planted without regard to the order so much enforced in the flower garden proper; yet this mixed border was, perhaps, more interesting than the others from the variety of its contents. Not having time to

notice all, I was obliged to be content with the following, which are in addition to those already described:—

Gold and Bronze and Golden Tricolor Varieties.—Duke of Edinburgh, a fine promising kind; Arthur II. Willa, also seems a good grower; Sultana, had been cut-in rather severely for propagation, a good indication of its merits; Empress Eugénie, also good; Princess Alice, Her Majesty, Egyptian Queen, Beauty of Ribblesdale, Sophia Casack, somewhat like Sunset, but with a scarlet flower and of much better growth; Florence, this has four distinct colours, and is besides of promising growth; Louisa Smith; Leah, somewhat like Florence; Beauty of Oulton, different from most of those previously mentioned.

Silver Tricolor Varieties.—Queen Victoria, good, Caroline Longfield, Glenny's Beauty, Italia Unita, Velvet Cushion, Empress Eugénie (of this I may be mistaken).

Golden-leaved Varieties.—Golden Spread Eagle, somewhat like Golden Fleece; Golden Christine, flowers like that popular variety.

Besides these there were several others of less merit, some of which doubtless may shine next year.

The Pelargoniums grown for their flowers were also well represented, though not to the same extent as the Golden Tricolors; and amongst others the following struck me as deserving attention:—

Enchantress.—A fine carmine, in the way of Glow-worm, but brighter, and with a shade more of blue in its composition. It is a half-Nosegay, of good habit, and will likely become a favourite when the Magenta class is called for.

Eclat.—Also a magenta-flowered Nosegay. Good and promising.

Gathorne Hardy.—Bright scarlet Nosegay. Truss very large and fine.

Grand Duke.—Rosy scarlet. Very large truss; in fact, one of the largest I am acquainted with. It is also of the Nosegay section.

Rebecca.—A well-known kind, grown in most places, and one that will maintain a position for years.

Dr. Hogg.—Magenta. Good, one of the best.

Le Grand.—A fine carmine. Large truss.

Nimrod.—Scarlet. Very large truss.

Smith's Warrior.—Scarlet. Very large truss.

Leonidas.—Also fine scarlet.

Besides the above there were many others, but some had been so recently cut-in for propagation, that their character could not be easily ascertained. Many old varieties were represented, but in less numbers, as the culture and propagation of new kinds seemed the chief objects; and as a proof of this, Mrs. Pollock was not grown to an equal extent with newer kinds, although Mr. Potton had disposed of many thousands of plants of it during the last three seasons. Of the older flowering Pelargoniums only specimens of the best were retained to compare with newly-sent-out varieties, and if the latter failed to be improvements they were not recommended.

The readers of the Journal will, perhaps, be anxious to know how so many varieties of Pelargoniums are propagated and wintered, and the extent of glass at command appears inadequate even to those best versed in Pelargonium culture, but no doubt every inch of space is closely crammed. Propagation is a more easy affair at this season than in spring, and there is no coddling in the treatment pursued. Large pots and pans full of cuttings were standing about in various places, some being in front of a viney in what is called a Dutch pit, others placed out of doors.

The glass structures are not numerous. Two span-roofed plant houses, not large, and a propagating house adjoining, with two lean-to vineyries, were nearly all the glass structures at command; and as the place is a private one rather than a nursery, the other requirements of the proprietor, J. J. E. Wilson, Esq., had to be attended to. The plant houses were small, but broad shelves had been placed over the pathways, on which choice bedding Pelargoniums in thumb pots were luxuriating in the full sun. I imagine the vineyries are kept hard at work in early spring. An ingenious contrivance had been adopted to enlarge the two old lean-to vineyries that had occupied the site for many years, and were quite worn-out, as well as the Vines in the inside. They had originally been about 14 feet wide, with high fronts, so when new ones were projected the same angle was retained, but a width of 26 feet was arranged, and a border and young Vines planted in the part newly covered in, while the old Vines were retained for one year. Although the young Vines were only planted in April, 1867, upwards of 150 lbs. of Grapes had been cut this

season from them, the house being 46 feet long by 26 feet wide, and the Vines all that could be wished for. The other vineyry was also promising well; it is older and of the same width as that just referred to, but only 31 feet long.

A singular feature, however, in these houses is that the fronts of both were occupied by what are called Dutch pits. About a yard of the lower part of the roof is made to hinge in lights, or rather it is entirely independent of the house, as the waterspout runs along where the pit unites with the front of this house. This Dutch pit can either be made to communicate with the house, or be shut off from it by boarding attached to the back; but I believe in winter it is united with it on account of the heat which, I presume, it receives from the vineyry. It formed an excellent place for propagating Pelargoniums, and was well filled. Mr. Potton's skilful treatment of this class of plants is so well known, that an eminent London grower had sent him some of his difficult varieties to operate upon, and there they were in all the sturdy health of common kinds; but Mr. Potton wisely confines himself to cultivating and propagating only the very best varieties in each section, and although some seedlings of his own were shown me, I feel certain if another known kind were equally good we should hear no more of the seedling. This, however, is at variance with the practice of many, who seem to think that names cannot be multiplied too much.—J. ROBSON.

PALMS FOR DECORATING ROOMS.

My attention has been called to a discussion in your Journal on Palms, originating in an article of mine in "The Gardener." Palms certainly are to be bought cheaper in any nursery to-day than they were a few years ago, and hence my remark which "PATELIN" alludes to. They are still, however, to be bought very much cheaper in Belgium than in Britain. In France they are cheap, but much dearer than in Belgium. I have purchased in both countries, but I always preferred the Belgian stock to the French, for this reason, that the plants are grown stockier and cleaner, and hence are better adapted for a sitting-room, and its vicissitudes.

I append a list of Palms, most of which I have proved to be suitable for general house decoration, or a cool glass house.

Areca Banerii (syn. Sea-	Jubea spectabilis (syn.
forthia robusta)	Cocos chilensis)
Brahea dulcis	Phoenix dactylifera
Chamærops excelsa	farnifera
Fortunei	humilis
Ghiesbreghtii	leuconensis
humilis	pumila
palmetto	reclinata
sinensis	sylvestris
tomentosa	tennis
Cecoc anstralis	Rhaphis flabelliformis
Bennettii	Sabal Adansonii
campestris	Moeini
Corypha australis	Seuferthia elegans
Diplorhynchium maritimum	Thrinax parviflora
Latania borbonica	tunicata

All these will do well in a cool house without a draught all the year round, or every other week in a sitting-room with proper attention as to watering with tepid water, and sponging frequently the leaves when dusty.

There are many other species that would do with careful, thoughtful attention, but in the hands of the inexperienced they would pine and die. Those named may be purchased at from one to twenty francs each, a price low enough for anyone who has a real love for plants in a sitting-room.—H. K.

VARIEGATED BORECOLE.

In your notice to a correspondent, page 175, regarding variegated Borecole you remark, "Your plants ought by this time to have shown variegation." We trust "J. A." has not thrown his plants away, and that he will not do so for some time yet. For the encouragement of him and others who may be despairing of their plants not yet showing variegation, we may mention that out of some 12,000 which we have planted out (sown in May), very few have as yet assumed variegation. With us they do not show variegation until the plants finish their rank growth and expend themselves. This season we do not expect they will show decided variegation, or be in a suitable state for being transplanted into their winter quarters, for at least two months. When they begin to make a fresh growth in spring,

it is then their bright and dazzling colours appear to the greatest advantage. We plant in an exposed situation and in poor soil, and our plants are always dwarf and stubby.

We think that if "J. A." will examine the centre of his plants he will find the variegation appearing even now, and upon those plants which have the plainest and roughest-looking outside leaves. We find the variegation does not appear until the plants receive a check from frost. The specimen leaves we have sent for your inspection are a few of the first variegated leaves which have appeared, and are taken from the heart of the plants. These leaves are but small yet, but by the time we require them for winter decoration they will have attained their full size.—STUART & MEIN, *Kelso, N.B.*

FUNGI CONNECTED WITH DISEASE— DARWINIAN THEORIES.

In his opening address as President of the Biological Section of the British Association, the Rev. M. J. Berkeley, after alluding to personal matters that had hitherto prevented him from carrying out his original intention of instituting a course of experiments illustrative of the theories which have lately been broached by Dr. Hallier and others respecting the origin of cholera and some other formidable diseases, proceeded as follows:—

Few points are of greater significance than those which touch upon the intimate connection of animal and vegetable life. Fresh matter is constantly turning up, most clearly indicating that there are organisms in the vegetable kingdom which cannot be distinguished from animals. The curious observations which showed that the protoplasm of the spores of *Botrytis infestans* (the Potato mould) is at times differentiated, and ultimately resolved into active flagelliferous zoospores, quite undistinguishable from certain Infusoria, have met their parallel in a memoir lately published by Messrs. Faminzin & Boranetzky, respecting a similar differentiation in the gonidia of Lichens belonging to the genera *Physcia* and *Cladonia*. It is, however, only certain of the gonidia which are so circumstanced: the contents of others simply divide into motionless globules.

A still more curious fact, if true, is that described by De Bary, after Cienkowski, in the division of Fungi known under the name of Myxogastres or false puffballs. Their spores, when germinating, in certain cases give rise to a body not distinguishable from *Amoeba*, though in others the more ordinary mode of germination prevails. In the first instance De Bary pronounced these productions to belong to the animal kingdom, so striking was the resemblance; but in our judgment he exercised a wise discretion in comprising them amongst vegetables in a late volume of Hofmeister's *Handbuch*.

The point, however, to which I wish to draw your attention, and one of great interest if ultimately confirmed, is that the gelatinous mass produced either independently, or by the blending of these *Amoeboid* bodies, is increased, after the manner of true *Amoebae*, by deriving nourishment from different organisms involved by accident from the extension of the pseudopodia. These strange bodies, according to our author, behave themselves precisely after the same manner as those enclosed accidentally in undoubted animals. If this be true, it shows a still more intimate connection, or even identity of animals and vegetables than any other fact with which I am acquainted.

You are all doubtless aware of the important part which minute Fungi bear in the process of fermentation. A very curious contribution to our information on cognate matters has lately been published by Van Tieghem, in which he shows that tannin is converted into gallic acid by the agency of the mycelium of a species of *Aspergillus*, to which he has given the name of *Aspergillus niger*. The paper will be found in a late number of the "*Annales des Sciences Naturelles*," and is well worth reading.

We now come to the subject which I mentioned at the beginning of this address—viz. the theory of Hallier respecting the origin of certain diseases. His observations were at first confined to Asiatic cholera, but he has since made a communication to the authorities of the medical department of the Privy Council Office to the effect that in six other diseases—typhus, typhoid, and measles (in the blood), variola, variola ovina, and vaccinia (in the exanthemes), he has found certain minute particles which he calls micrococci, which under culture experiments give, for each of the above-mentioned diseases, a constant and characteristic fungus. He states that in variola he gets the hitherto unknown pycnidia of *Eurotium herbariorum*; in vaccinia, *Aspergillus glaucus*, Lk.; in measles, the true *Mucor Mucedo* of Fresenius; in typhus, *Ichizopus nigricans*, Ehrenberg; and in typhoid, *Penicillium crustaceum*, Fries. He adds that the culture experiments, especially with the variola diseases, have been so very numerous as to exclude from the results all supposition of accident—that different districts, different epidemics, and different times have given identical results. I am anxious to say a few words about the subject, because most of the reports which have been published in our medical journals give too much weight, in my opinion, to his observations, as though the matter had been brought to a logical conclusion, which is far from

being the case. I am happy to say that it has been taken up by De Bary, who is so well calculated to give something like a conclusive answer to the question, and also that it has been taken in hand by the medical authorities of our army, who are about to send out two of their most promising young officers, perfectly unprejudiced, who will be in close communication both with De Bary and Hallier, so as to make themselves perfect masters of their views, and to investigate afterwards the subject for themselves.

The fault, as I conceive, of Hallier's treatise, is that while his mode of investigation is unsatisfactory, he jumps far too rapidly to his conclusions. It is quite possible that certain Fungi may occur constantly in substances of a certain chemical or molecular constitution, but this may be merely a case of effect instead of cause. Besides, as I conceive, the only safe way of ascertaining what really originates from such bodies as those which he terms micrococci, or the larger ones commonly called yeast globules, is to isolate one or two in a closed cell so constructed that a pellicle of air, if I may so term it, surrounds the globule of fluid containing the bodies in question, into which they may send out their proper fruit—a method which was successful in the case of yeast, which consists of more than one fungus, and of the little *Sclerotium*, like grains of gunpowder, which is so common on Onions. Any one who follows the growth of moulds on moist substances, and at different depths, as paste of Wheat or rice flour, will see that numberless different modifications are assumed in different parts of the matrix, without, however, a perfect identification with Fungi of other genera. Some of these will be seen in the figures I have given in the "Intellectual Observer" of different forms assumed by the moulds to which that formidable disease, the Fungus foot of India, owes its origin. This is quite a different order of facts, from the several conditions assumed by the conidiiferous state of some of the vesiciferous moulds. As for example *Botrytis Jonesii*, which has been ascertained to be a conidiiferous state of *Mucor Mucedo*, while two forms of fruit occur of the same mould in what is called *Asophora elegans*, or the still more marvellous modification which some of the *Mucors* undergo when grown in water, as evinced by some of the *Saprolegniae*, the connection of which was indicated by Carus some fifty years ago, but which has never been fully investigated.

When Hallier intimates that he has raised from cholera evacuations such a parasite as *Urocystis oculenta*, he should have been content with stating that a form of fructification occurred resembling, but not identical with, that Fungus. Indeed a comparison with authentic specimens of that species, published by Rabenhorst, under the generic name of *Ustilago*, shows that it is something very different, and yet the notion of cholera being derived from some parasite on the Rice plant rests very much on the occurrence of this form. But even supposing that some *Urocystis* (or *Polycestis* as the genus is more commonly named) was produced from cholera evacuations, there is not a particle of evidence to connect this with the Rice plant. In the enormous collections transmitted by Dr. Curtis from the Southern United States, amounting to 7000 specimens, there is not a single specimen of Rice with any endophytic Fungus, and it is the same with collections from the East. Mr. Thwaites has made very diligent search, and employed others in collecting any Fungi which may occur on Rice, and has found nothing more than a small superficial Fungus nearly allied to *Cladosporium herbarum*, sully the glumes exactly as that cosmopolitan mould stains our cereals in damp weather. Rice is occasionally ergoted, but I can find no other trace of Fungi on the grains. Again, when he talks of *Tilletia*, or the Wheat Bunt, being derived from the East—supposing Wheat to be a plant of Eastern origin, there is no evidence to bear out the assertion, as it occurs on various European Grasses; and there is a distinct species which prevails on Wheat in North Carolina, which is totally unknown in the Old World.

I might enter further into the matter, were it advisable to do so at the present moment. All I wish, however, is to give a caution against admitting his facts too implicitly, especially as somewhat similar views respecting disease have lately reached us from America, and have become familiar from gaining admittance into a journal of such wide circulation as "*All the Year Round*," where Hallier's views are noticed as if his deductions were perfectly logical.

The functions of spiral vessels, or of vascular tissue in general, have long been a subject of much controversy, and few matters are of more consequence as regards the real history of the distribution of sap in plants. A very able paper on the subject, to which allusion was made by Dr. Hooker in his address, has been published by Mr. Herbert Spencer (than whom few enter more profoundly into questions of physiology), in the "*Transactions of the Linnean Society*." By a line of close argument and observation he shows, from experiments with coloured fluids capable of entering the tissues without impairing vitality, and that not only in cuttings of plants, but in individuals in which the roots were uninjured, that the sap not only ascends by the vascular tissue, but that the same tissue acts in its turn as an absorbent, returning and distributing the sap which has been modified in the leaves. That this tissue acts some important part is clear from the constancy with which it is produced at a very early stage in adventitious buds, establishing a connection between the tissues of the old and new parts. This appears also from the manner in which in true parasites a connection is established between the vascular tissue of the matrix and its parasite, as shown by our President in his masterly treatise on *Balanophora*, and more recently by Solms-Laubach in an elaborate memoir in *Pringsheim's Journal*. It is

curious that in organs so closely analogous to the tracheæ of insects a similar connection should long since have been pointed out by Mr. Nowport, in the case of certain insect parasites.

A circumstance, again, which constantly occurs in the diseases of plants confirms the views of Mr. Herbert Spencer. Indisposed Turnips, Grapes, Potatoes, &c., it is especially the vascular tissue which is first gorged with the umlutes which are so characteristic of disease.

Monsieur Casimir De Candolle, in a clever memoir on the morphology of leaves, has come to the conclusion, after studying the arrangement of their vascular tissue, that they are branches in which the side towards the axis, which he calls the posterior, is atrophied. This subject has been followed out in those organs which are considered as modifications of leaves, as, for example, stamens, in which he finds sometimes the posterior side, sometimes the anterior, atrophied. If his theory is true, this would result from the way in which they originated, and the reference they bore to contiguous organs. The subject is well worth attention, and may eventually throw considerable light on those anomalous cases in Teratology which will not accommodate themselves to the usual theory of metamorphosis. Some of these cases are so puzzling and complicated, that a very clever botanist once told me, "Monstrous flowers teach us nothing,"—not meaning to abjure all assistance from them, but simply to indicate that they may be deceptive. Such flowers as double Primroses, and the strange developments on the corollas of some Gloxinias, may possibly receive their explanation from a careful study of the course of the vascular tissue. As the colour on the anterior and posterior order in the latter case is reversed, the doctrine of dedoublement does not at all help us.

Hofmeister, in his "Handbuch der Physiologischen Botanik," has an important chapter on free-cell formation, which at the present moment is of great interest as connected with Mr. Darwin's doctrine of Pangenesis. Mr. Rainey has showed that the formation of false cells takes place in solutions of guta and other substances, and if this is the case where no vital agency is concerned, we may well be prepared for the formation of living cells in organisable lymph, or in other properly constituted matter. The curious cell-formation of Gum Tragacanth may be an intermediate case. Be this, however, as it may, we have examples of free-cell formation in the formation of nuclei, in the embryos of plants, and above all in the ascæ of ascomycetous fungi. In plants whose cells contain nuclei, new cells are never formed without the formation of new nuclei, the number of which exactly corresponds with that of the new cells.

It would be unpardonable to finish these somewhat desultory remarks without adverting to one of the most interesting subjects of the day,—the Darwinian doctrine of Pangenesis. After the lucid manner, however, in which this doctrine was explained by Dr. Hooker in his opening address, I should be inclined to omit it altogether had I not looked at it from a somewhat different point of view, so that I should not be trespassing upon your time in going over the same ground. Others, indeed, as Owen and Herbert Spencer, have broached something of the kind, but not to such an extent, for the Darwinian theory includes atavism, reversion, and inheritance, and embraces mental peculiarities as well as physical. The whole matter is at once so complicated, and the theory so startling, that the mind at first naturally shrinks from the reception of so bold a statement. Like everything, however, which comes from the pen of a writer whom I have no hesitation, so far as my own judgment goes, in considering as by far the greatest observer of our age, whatever may be thought of his theories when carried out to their extreme results, the subject demands a careful and impartial consideration. Like the doctrine of natural selection, it is sure to modify, more or less, our modes of thought. Even supposing the theory unsound, it is to be observed, as Whewell remarks, as quoted by our author, "Hypotheses may often be of service to science when they involve a certain portion of incompleteness, and even of error." Mr. Darwin says himself that he has not made Histology an especial branch of study, and I have therefore less hesitation, though "*impar congressus Achilli*," in expressing an individual opinion that he has laid too much stress on free-cell formation, which is rather the exception than the rule. Assuming the general truth of the theory, that molecules endowed with certain attributes are cast off by the component cells of such infinitesimal minuteness as to be capable of circulating with the fluids, and in the end to be present in the unimpregnated embryo cell and spermatozoid, capable either of lying dormant or inactive for a time, or when present in sufficient potency, of producing certain definite effects, it seems to me far more probable that they should be capable under favourable circumstances of exercising an influence analogous to that which is exercised by the contents of the pollen tube or spermatozoid on the embryo sac or ovum, than that these particles should be themselves developed into cells; and under some such modification I conceive that the theory is far more likely to meet with anything like a general acceptance. Be this, however, as it may, its comprehensiveness will still remain the same. We must still take it as a compendium of an enormous mass of facts, comprised in the most marvellous manner within an extremely narrow compass.

I shall venture to offer a very few words in conclusion, which perhaps may be thought to have too theological an aspect for the present occasion.

It is obvious how open such a theory is to the charge of materialism. It is an undoubted fact, however, that mental peculiarities and endowments, together with mere habits, are handed down and subject to the same laws of reversion, atavism, and inheritance as mere structural

accidents, and there must be some reason for one class of facts as well as the other; and whatever the explanation may be, the hand of God is equally visible and equally essential in all. We cannot now refer every indication of thought and reasoning beyond the pale of humanity to blind instinct, as was once the fashion, from a fear of the inferences which might be made. Should any one, however, be still afraid of any theory like that before us, I would suggest that man is represented in Scripture as differing from the other members of the animal world, by possessing a spirit as well as a reasoning mind. The distinction between *psyche* and *pneuma* which is recognised by the Germans in their familiar words *seele* and *geist*, but which we have no words in our language* to express properly, or in other terms between mere mental powers which the rest of the creation possess in greater or less degree in common with ourselves, and an immortal spirit, if rightly weighed, will perhaps lead some to look upon the matter with less fear and prejudice. Nothing can be more unfair, and I may add unwise, than to stamp at once this and cognate speculations with the charge of irreligion. Of this, however, I feel assured, that the members of this Association will conclude with me in bidding this great and conscientious author God speed, and join in expressing a hope that his health may be preserved to enrich science with the results of his great powers of mind and unwearied observation.

POTATOES AND BEES

AT THE WOODSTOCK AGRICULTURAL AND HORTICULTURAL ASSOCIATION'S SHOW.

(From a Correspondent.)

On the 15th inst. this annual Exhibition took place in Blenheim Park. The Potatoes and other roots exhibited, notwithstanding the hot dry season, could scarcely be surpassed.

Potatoes were shown in a special collection of twenty-four kinds by Mr. Robert Fenn, of the Rectory at Woodstock; and there was really something for the Potato grower to learn by inspecting the many varieties, with labels attached to each basket indicating the particular sort, nature, and growth. Mr. Fenn seems quite at home in this, as in many other branches of horticulture.

Amongst the sorts we particularly noticed were Fenn's Onwards, a seedling of his raising, originating in a cross between Jackson's Kidney and the Fluke. It is an excellent flattish-round sort, which can be grown both as an early and second early, and makes a first-rate store Potato, as samples of it were shown in fine condition, although dug up in 1867, as were also those of Paterson's Victoria, Daintree's Kidney, and Rivers's Royal Ashleaf, and that fine sort Taylor's Yorkshire Hero, representing four generations—viz., tubers of this year, of last year, and of 1866. Some of the last were actually producing "young Potatoes" internally, and bursting forth from, so to call it, suppressed vitality. Mr. Fenn is an indefatigable cross-breeder of Potatoes, and he has this year originated some two hundred seedlings, many amongst them promising to become very fine sorts.

Mr. Fenn's collection of what he so happily terms "garden economies" had an especial interest. We will first mention an assortment of British home-made wines, consisting of Grape, Gooseberry, and Rhubarb, and Rhubarb and Gooseberry mixed in imitation of Champagne. Several of these were pronounced by a jury then and there assembled as being of very fine quality. In English Champagne wines Mr. Fenn may be termed great, and some of his stocks might compete with what are occasionally thought to be the finest brands of continental production. We were treated to an Espérance port, which had been laid down in bottle three years. It was really a fine wine, and the bottle showed a good "crust;" also Espérance Grape wine of 1866 drawn from the wood (a thirty-three-gallon cask), now in use for daily table purposes. In partaking of these innocuous wholesome beverages the Judges, by their rosy countenances and liveliness, indicated that the wines were not without strength. Furthermore, as like is said to beget like, a competition was brought about by the Rev. W. A. Plumptre, Mr. J. Parker, and Mr. J. Morris, all of Woodstock, sending samples of the above-named wines made after Mr. Fenn's methods. Excellent characters were awarded to some of the samples; those of Mr. Plumptre's effervescent Espérance wine being considered so palatable that not a glass was left in the bottles to tell a tale! Mr. Fenn has given to the world his methods of manufacturing these wines in Nos. 589, 592 (old series), and 235, 236 of THE JOURNAL OF HORTICULTURE.

Another branch of Mr. Fenn's "garden economies" exhibited was a system of bee-keeping, comprising "Fenn's Woodstock Alliance Hive, adapted for cottagers, on the depriving system, without destroying the bees, and showing the domestic economy derived from it." Finding as the result of several years' experience that the improved principles of Payne's and other cottage hives, in so far as they had become developed, were, according to his idea, still defective, he set himself to further improve a cottage hive to his ideal standard. His "Alliance hive" seems to answer exactly the end sought. Virgin honeycombs were exhibited in glass and straw supers upon the tops off the hives, to explain exactly how the bees worked in them. There

* A proof of this poverty of language is visible in the words used in our translation for *psychikon* and *pneumatikon*, natural and spiritual, their proper meaning being a body with a soul, and a body with a spirit.

were also "Fenn's Breakfast Honey Glasses," filled with honeycomb, with run honey gathered by the bees from the Sycamore and Lime tree blossoms; white and yellow wax, with accompanying cream, for the purpose of cleaning furniture; dubbing for waterproofing sheeting boots, &c., made from the wax; methglin or mead—the drink of our forefathers; honey beer (brewed the same as for malt liquor, by mixing water with honey to the specific gravity of about 120 for table beer, and 220 to make a "sweet wort" for ale. It is then boiled with 1 or 1½ lb. of hops, to about 80 gallons of the wort, and the fermentation is carried out through the agency of yeast exactly as for a brewing of malt and hops); and vinegar made from honey. These productions had been awarded special first-class certificates at former shows of the Royal Horticultural Society. Mr. Fenn has also published his system of bee-keeping in Nos. 639, 652 (old series), and 4, 10, 21, 22, 29, 40, 43, 46, and 48 of *THE JOURNAL OF HORTICULTURE*.

Mr. James Morris exhibited some of the finest glasses of honeycomb we ever saw, for which he gained the first prize; and Miss Heynes, of Woodstock, exhibited even superior samples of better finish, but in glasses of a much smaller diameter. The honey was produced on the above system.

HYPOCAUST HEATING AT LEEDS CASTLE, KENT,

THE SEAT OF C. WYKEHAM-MARTIN, ESQ., M.P.

THE importance of artificial heat obtained in an economical manner by the aid of an efficient apparatus, can be nowhere more fully recognised than in the southern counties of England, remote as they are from the coal districts, those dear "black diamonds," the command of which at a cheap rate enables our northern brethren to boast of their splendid collections of Orchids, and other plants requiring a high temperature. That the method of heating invented, or rather resuscitated by Mr. Wykeham-Martin, possesses great merit, and likewise offers many advantages, I am now fully convinced. It is not, however, my purpose to attempt any description of the heating apparatus or houses, as that has already been done by Mr. Robson, in page 361, Vol. XI., but rather to offer a few notes of what is being done, and also as to the results already obtained.

The house to which the hypocaust system was first applied, is an ordinary lean-to, and is used chiefly for the cultivation of Pine Apples. The Pine plants are planted out in a bed on the floor of the house, the sides of which are formed in an ornamental manner of cement. This bed only occupies the centre of the house, leaving ample space for pathways, and for other purposes. Some good fruit have been cut, and the plants at the present time have a fair crop. Although, owing to some slight misadventure, the fruit is not of a large size, yet it is quite good enough to prove that first-class Pines can be grown by this system of heating in a much more economical manner than by any other. Not a particle of coal or cinder has been used in any of the fires; indeed, as illustrative of the easy way in which heat can be had, I may mention, that when the soil was first placed in the Pine-bed, one entire faggot was set fire to in the furnace, over this faggot a quantity of sawdust was thrown, and by the time this was burned up the soil was heated to 75°.

A new house has been lately added to the range, and is, I believe, intended for an orchard house. The roof has a very light appearance, as it is a fixture—without moveable sashes, and no heavy rafters have been used. It is ventilated by means of the front sashes, and by shutters in the back wall. This house is heated by a hollow chamber under the footpath, which is paved with slabs formed principally of Portland cement and broken bricks. These are made by Bow, of Maidstone, and are said to be very cheap and durable; they certainly form an admirable material for paving purposes.

But it is to the heated bed, which has no regular glass roof, and is as much exposed as any other plot of ground, a miniature kitchen garden in fact, to which I would wish more particularly to call attention. Most kinds of vegetables have been here produced, both early and in excellent condition, and they have only been protected from frost and cold winds in the early spring months by means of thin wooden screens raised on legs about 15 inches above the soil. These screens are also, doubtless, most useful in checking radiation quite sufficiently to guard the young and tender crops from any chill to which they might otherwise be subjected if fully exposed to the cold night air. Of the crops taken this year—Onions were fit for use on April 6th; Potatoes, April 2nd; Turnips, May 6th; Carrots, May 6th; and Peas, May 21st. At the time of my visit, August 29th, various crops were growing in the bed, and not the least interesting were some excellent crops of the Scarlet-fleshed

Pine-Apple Melon, of which both the foliage and fruit were all that could be wished. The Melons, and some Cucumbers, are grown under a useful kind of span-roofed portable frame, invented by Mr. Wykeham-Martin. The frames are made entirely of iron, and are glazed from top to bottom with 15-oz. glass, which gives them a very light appearance. They are 6 feet long by 2 feet 8 inches wide, and the span-roof rises about 18 inches or 2 feet high. The span-roof is separate from the lower part, and is lifted off and on by two iron handles at each end. The principal merit of these frames consists in the use of T and angle iron, which can be bought in London at 55s. per hundredweight. The entire cost of each frame when glazed and completed, is £2 5s. The accompanying sketch represents one of these frames, of which six are now in use on the bed in question.

As regards fuel, as I have already stated, nothing in the shape of coal is ever used. In the severest weather abundance of heat is obtained by using logs of wood, for the furnaces are so commodious that whole trees require but very little sawing-up to fit them for fuel, and during the present summer, what little artificial heat has been required, has actually been obtained by burning old Cabbage stalks, Potato haulm, or, in fact, any garden refuse which could be had, so that it will be seen that after the first expense of building, the cost of fuel is of very little moment.

What gardener is there who would not hail with delight the idea of a constant supply of steady bottom heat, aye, even if applied to that snug warm border so called, but to which he would always welcome a little more solar heat to hasten on his tardy spring crops? Moreover, now that bedding plants are required in such enormous quantities for the flower garden, what can be more serviceable than a plot of heated soil, over which a glass case has only to be placed to form, without any further care, one of the most excellent propagating houses it is possible to have?—EDWARD LUCKHURST, *Egerton House Gardens, Kent*.

CAUSE OF COLOUR AND FLAVOUR IN FRUIT.

WITH reference to the letter of "J. F." (page 204), I would say that the high colour and racy flavour, which are observed in fruit ripened under favourable circumstances in the open air, arise probably, at least in part, from a cause which, I believe, has not hitherto been brought into notice—namely, that the chemical solar rays, which are quite distinct from the luminous and heating rays, pass with difficulty through glass.—G. S.

GRAPE VAGARIES.

IN a span-roof vineyard here measuring 93 feet long, in three divisions of 30 feet each, and which was planted in 1862, the roots being inside, the Black Hamburgs used to be ripe by the 1st of August. This year, however, though the Vines were forced as early, and there was no visible difference in the treatment, while some bunches are ripe, many are merely colouring now in the two houses nearest the stove, although in the same houses Muscats, Lady Downe's, and other sorts, were quite ripe some time ago. In the third or end house (on three-year-old and small Vines), there has been merely sun heat since July, yet there the Black Hamburgs were quite ripe a month ago, and black as sloes. The Vines are heavily cropped, but not much more so than usual.

Two Muscat Hamburgs, one on its own roots, the other inarched on a Black Hamburg, have set their bunches well, but every one contains about one-tenth of berries, quite as large as the rest, that are merely coloured, and acid, while the others are blue black, and were ripe long ago. I see no difference in the stones in the two kinds of berries, ripe and acid. Both sorts of berries seem perfect except as to ripening.

How can I best make a two-year-old Trentham Black Vine take the place of a Muscat Hamburg six years old, on its own

roots, and with a stem about 6 inches or more in circumference, within 5 feet of the Trentham? I dislike throwing away so very strong-growing a Muscat Hamburgh, if it would by grafting or inarching make a good mother for the Trentham.—J. MACKENZIE, M.D.

[If the stem of the Muscat Hamburgh is deemed so valuable you might turn the stem, if possible, of the Trentham Black, and inarch them together. We do not see any other way you can use it, unless you leave the Trentham alone, and fresh graft the other in the spring, or inarch after growth commences.

We are quite unable to account for the Hamburghs not ripening, when Muscats, &c., are ripe, unless the house was kept too hot for them in the hot weather. Neither can we assign a reason for the Muscat Hamburgh ripening unequally, unless it was that deficient moisture at the roots, combined with heavy cropping, rendered the supply of sap deficient.]

POMOLOGICAL GLEANINGS.

MADAME TREYVE PEAR.—One of the most beautiful, perhaps the most beautiful and finest summer Pear we have

seen, is a variety sent us by Mr. Rivers, and of which we furnish our readers with a figure in our present number. As will be seen by the figure it is of good size, but it requires the painter's pencil to give any idea of the colour, which on the side exposed to the sun is of a brilliant vermilion crimson, more brilliant even than Forelle, which is one of the highest-coloured of Pears. On the shaded side Madame Treyve is of a pale straw yellow, but on that next the sun, and extending over three-parts of the surface of the fruit, it is as we have already described it, and dotted with minute yellow dots. The eye is very small and open, and set in a narrow round basin. The stalk slender, half an inch to three-quarters long, set in a round narrow cavity. Flesh white, like that of Forelle, melting like a Peach, very juicy, rich, and sugary, with a delicate and highly refined aroma. A most delicious Pear, ripe in the beginning of September.

PROPAGATING VARIEGATED PELARGONIUMS.

THERE is much danger of many of these beautiful plants being lost to our gardens from want of proper knowledge in those who attempt their propagation. Most persons, who either

raise one as a seedling, or buy one as an expensive little plant, are too anxious to obtain a cutting from it. Before the plant has time to become strong and vigorous a miserable little cutting is taken, which can hardly make root, and becomes unhealthy before it has time to grow. I feel convinced this practice has ruined the constitution of plants which would otherwise have produced valuable varieties. It is the same to a certain extent with almost all new plants. New Roses, new Dallisias, &c., which have been over-propagated, require time to recover strength before an opinion can be safely formed of their merits. Variegated plants, however, are more easily and permanently injured. With these more particularly I would say, "The greater haste, the less speed." Put in large cuttings and you will have healthy plants.—J. R. PEARSON, *Chilwell*.

NEW ROSES.

YOUR correspondent "DEVONIENSIS," evidently wants a chat about Roses, and specially in reference to new varieties. I am very shy of buying novelties, the per-centage of the bad to the good Roses is so great. The best Roses of later date that I have grown, and to which I will give a full certificate, are Antoine Ducher, Alfred Colomb, Prince de Portia, and Charles Verdier. Whoever buys these (being a cultivator), must be highly pleased.

Heaps of trash are sent out every year, and the prizes bear no relation to the blanks. I am distressed to see so many worthless Roses retained in catalogues, and such noble Roses discarded from catalogues which are otherwise good and select. What novelties, in their lines of colour (I include excellent habit), are equal or superior to Baronne Prevost, Duchesse d'Orleans, Sœur des Anges, Gloire de Vitry (first-rate on its own roots), Caroline de Sansal, and Monsieur de Montigny? How nobly have these magnificent neglected ones acquitted themselves this critical year. These I can buy at 9d. per plant; compare with them the wretches sent out annually at 3s. 6d. per plant, or more.

We want novelties new in character rather than in name. We want not merely good Roses, but Roses better in the same line of colour than those we already have. "DEVONIENSIS" is sanguine! How long will it take to beat, in the line of crimson (I include good constitution and habits), these crimson Roses—namely, Charles Lefebvre, Sénateur Vaisse, Alfred Colomb, Antoine Ducher, Lord Macaulay, Duchesse de Caylus, Madame Victor Verdier, Madame Julie Daran, Maréchal Vailant, Leopold Premier, and Madame Boutin? Besides these, there are others very excellent in the line of crimson, as Baronne Adolphe de Rothschild, Lady Suffield, and François Lacharme. I should not like to wait for my breakfast till I could produce a Rose equal to any one of the above Roses. It is, however, now time to pay attention to the queries sent by "DEVONIENSIS."

Mademoiselle Jeanne Marix is of fine growth with fine foliage. It is a most promising Rose, but I have not had a full bloom. The early blooms did not open quite freely. I expect to find it next year a first-rate variety. Madame Alice Dureau is a nice Rose, and is about to bloom again. It is a good grower and free bloomer. La France came with one series of flowers on it and has produced two more since. It has a long neck, and, I think, is of Tea descent. It is distinct, and suited to dry weather or a conservatory. Its petals are incurved at the edges. I prefer Marguerite de St. Amand, and still more so, Charles Verdier, the best Rose of light colour that has been out since beautiful Sœur des Anges appeared. Madame Martin de Besse is a splendid grower with the finest foliage, but not sufficiently proved. I moved it, Jeanne Marix, and others on the 28th of August, before they had time to give a second series of bloom. Madame Rolland buds well, is a good grower, and will soon bloom again. Its first blooms were as good as I could expect from a weak plant. Of Marie Girod I bought twelve in dormant bud on the 6th of August. I cut them down at once, and eleven are growing freely, and some may yet bloom. The growth and foliage are first-rate. They were budded only six weeks before I bought them.

I met Mr. Keynes at the Blandford Show, and asked him to mark the best Roses of the year in his catalogue. He marked these:—Hybrid Perpetuals: Boule de Neige, Christina Nilsson, Elie Morel, Louis Balliat, Madame Rolland, Madame de Rothschild, Reine du Midi, Souvenir d'Adrien Bahivet, Souvenir de Caillat, and the Tea Rose, Reine du Portugal, which his catalogue describes as "deep bright yellow, sometimes shaded with

rose and copper, fine form, medium size, full. Opens shyly ! " I do not know this Rose. Buy Madame Margottin.

Pernet describes his Rose, Madame de Rothschild, as "*presque pleine*." It has been much puffed up by those sanguine rosarians whose signal attribute is that of deceiving (unintentionally), the Rose purchasers of the kingdom. I never recommend Roses fully that I have not bought, or would not buy. It takes three years to prove a Rose fully. Persons go to large establishments and view Roses under glass, and then give a character to the Rose that leads the uninitiated to think that the plant is grown out of doors, and, that where so grown, it will be the same fine Rose. The initiated know better. People, whether they buy or accept plants, should be most scrupulous in their recommendations. They are never given with a view to deceive, but are the expressions of kindness and respect. Purchasers of novelties can do no better than put themselves in the hands of our first-class nurserymen. They know but little, still, more than we know, about novelties.

I have these Roses on trial, only just come—Reine du Midi, Prince Humbert, Monsieur Noman, François Treyve, Louis Bulliat, Madame de Rothschild, Merveille d'Anjou, Marie Rady, Miss Ingram, Madame Barriot, Curé de Charentay, Marie Baumann, and others. Of them in due time I will give an account.

"DEVONIENSIS" says, "I think that Horace Vernet is quite above the common run of novelties." I differ. I have four plants which have not grown well; the petals are deep and fine-coloured, but there are not enough ranges, and the flower is crenulated, waved, or rough at the edges. It is the same colour as Fisher Holmes, which, also, though beautiful in colour, is not full enough. Thorin is fine, but has not yet been full enough. It is a good grower. "D." of Deal, comes on the 23rd of September, and I shall show him some good Roses.

I close with one word more about Charles Verdier. On the 6th of August, when I bought my dormant buds, and also some plants, at the Dorset Nurseries, Blandford, I told the foreman that it was first-rate in the light line. He said it would not open well. I told him it was from want of water. As I said before, the whole line "stood fast." This morning at the same time that I received the letter of "DEVONIENSIS," the foreman's changed opinion came to hand. "Some short time since (July 6th), you asked me my opinion of Charles Verdier. I was not able then to give an opinion of its merits, but I am quite sure if you saw the splendid blooms of it now out, you would pronounce it first-rate. It is 4 inches across. It resembles Abel Grand, but is fuller and more cupped." I bought seven plants of Abel Grand on the Manetti stock, on August 6th, and on the 9th of September it had dropped its leaves, made new shoots, and formed buds the size of a nut. I will show these to "D." of Deal, on the 23rd. Quick work! Hurrah for Manetti!—W. F. RADCLIFFE.

WORK FOR THE WEEK.

KITCHEN GARDEN.

Manures.—Take every opportunity of converting all refuse vegetable substances, scrapings of roads, cleanings of sheds, &c., into rich dressings for the garden, by watering with the liquid that distills from Melon grounds, dunghills, &c. New manures may be useful as auxiliaries, but there is nothing preferable for the production of good medium-sized high-flavoured vegetables to old hotbed dung, and the decomposing heap of those substances which can be collected in a garden. Weak solutions of guano, superphosphate of lime, &c., frequently applied, are found very serviceable to strong growing plants in pots, Cucumbers in boxes, &c., but the same apparent benefit is not the consequence of their application to crops in the open garden, though Cauliflowers are considerably improved, especially by guano, and Celery is rendered of a deeper green colour by the application of nitrate of soda, but in size and flavour it is not superior to that grown in the usual manner. However concentrated the strength of these manures, it must be evident that whatever their chemical influence, they can affect the mechanical texture of the soil but little, and hence, for rendering loose soils more retentive, and stiff soils more open, the old system of manuring must ever maintain a great superiority. It is true a similar mechanical effect might be produced by a proper application of lime, chalk, marl, and in extreme cases of clay or sand; but these operations involve both trouble and expense. Except the usual course of salading, there is very little sowing to be done for some time, and

as soon as the spring *Lettuces* and late *Cauliflower* plants are pricked or planted out, little more will be needed in the way of planting for a long time, except among the market gardeners, who will still plant out a large breadth of plants for late *Coleworts*. If, therefore, a few *Endive* plants are kept blanched, and the *Celery* rows are not allowed to go too long without earthing-up, you may turn your attention to forwarding work that will save time in spring. The cropping book will show what plots want trenching, and to what depth; never trench twice the same depth.

FRUIT GARDEN.

It is not too much to say that young fruit trees should never rest more than two years without being taken up and replanted nearer the surface, till they are twelve or fifteen years old. After they have attained a medium size of growth, the intervals of transplanting may be extended to three or four years. This is much better than allowing them to run half wild in the first instance, and then have to use severe and unnatural means to correct them afterwards. Nonpareil and other tender Apple trees infested with canker or otherwise unhealthy, may be improved by being taken up and replanted in fresh soil, using some turfy compost about their roots, their young growth being pruned-off two-thirds of its length, and they should be firmly tied up to stakes till they have a fresh hold on the soil. Early autumn pruning is necessary for the health and well-being of delicate fruit trees, not excepting even the Peach.

FLOWER GARDEN.

Every week now tells more or less on the appearance of the flower garden. Leaves from above and worms from below, with short days and long cold nights, will keep people busy here until frost. Many of the early kinds of Tulipa and Narcissus are now beginning to grow, and therefore to keep them out of the ground any longer will injure them. As, however, it is impossible to plant them permanently until the autumn plants are removed from the beds, it will be found a good plan to place them upon an inch or two of finely sifted leaf mould and sand, and to cover them several inches deep with old tan or leaf mould. In this situation they will make roots, and as soon as the beds are ready for their reception they may be removed to their proper positions with the soil adhering to their roots. The same observations apply to all sorts of bulbs or tuberous-rooted plants that are desired for early-spring decoration, as, for instance, Aneumones, Crocuses, Snowdrops, Hyacinths, Jonquils, and Crown Imperials. Continue at every favourable opportunity to pot-off Carnation layers; let the grass or leaves be dry, for when they are wet with rain or dew, the soil, which will sometimes lodge in the axils of the leaves, however carefully they may be handled, is difficult to be removed, and if not cleared out will prove detrimental to the plant during the winter. The layers must be put in a close frame for a few days till they have again struck root. The seedling bulbs of Tulips, when very small, are best in the ground, and small offsets of choice sorts had also better be planted. Any offsets of Auriculas, which may not have been ready earlier in the season, must now be removed, planting carefully round the rim of a 48-sized pot; water to settle the soil to the roots, and place in a situation free from drip or heavy rain. Continue to make the beds of Pansies for next year's blooming, and propagate by slips all that it is desirable to increase. Seedling Polyanthus may still be pricked-out, to become established before winter. Compost heaps should be turned, and all insects carefully picked out; a small quantity of quicklime will prove beneficial if added to the decayed turf intended for Tulips.

GREENHOUSE AND CONSERVATORY.

The Chrysanthemum will soon require the shelter of the greenhouse, particularly the early kinds, and some of the later sorts should be left out as long as a mat or two can secure them from the frost; this will prolong their succession. They will require some stakes; but avoid the exhibition plan of staking them, which, although necessary for bringing the flowers to view altogether at one time, is most unsightly for general purposes. As little water as possible should be scattered in the conservatory for the next ten months, as this dull season is enough of itself to damp off the flowers without such aids. Slight fires will also be necessary during the day if the house shows signs of dampness. This house and the late vinery should now be managed nearly alike. There are two varieties of Bignonia jasminoides in cultivation, one of which is a very shy bloomer, and ought to be discarded; the other is the finest of our hardy greenhouse climbers. Cuttings of the latter may

be struck any time before the end of October, and they root as freely as Willows, and will blossom all through next summer in very small pots.

STOVE.

There is no variation in the treatment of this house worth noticing this week.

PITS AND FRAMES.

Half a dozen plants of the Prince of Orange Pelargonium, stunted all the summer, and lately planted in one large pot, will now be ready to be removed from the cold pit to the conservatory, where they will flower all the winter. It is rather too soon yet to take the Heliotropes in-doors, so many of them being yet to be seen in the beds outside. Smith's Giant, or Shrubland Scarlet Pelargoniums, struck last May or June, will now be fine-sized plants to introduce into rooms, &c., where such furnishings are wanted. These are among the best to stand over the dull months. It is now time to place young Gardenias, Neriums, and Orange trees in their winter quarters. A cold pit from which the frost can be excluded is the best place for them, as they are always kept in the smallest pots into which the roots will go, and force best when thus underpotted. It often happens that their roots perish during winter. To prevent this it is a good plan to turn them out of the pots now, and plunge the balls in a thin layer of light earth during the period of rest; but as Gardenias will flourish in peat only they should be plunged in it.—W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

Celery.—In writing rather largely on the treatment of this vegetable last week, we forgot again to draw the attention of those who like Celery, and have little ground, to the Dwarf White Incomparable, which, though it grows slowly and never becomes high, blanches quickly, and from plants 15 or 18 inches in height you can always send a foot in length to table. A bed 4 feet wide will grow three rows admirably, and 2 feet at most on each side will be enough to earth it up. But for growing other crops on the ridges, 18 inches on each side would be ample space; so that in a width of 6 or 7 feet the amateur may have three rows of one of the sweetest kinds of Celery for the table. Tall Celery is not to be despised by any means, but in these giant heads the eatable part is not in proportion to the general bulk. We found last winter and spring that this Dwarf White stood as well as the Red.

Tomatoes.—Disleafed these rather freely to let the sun to the fruit. There is so much moisture in the stems that the fruit ripens with but little foliage. After this season it is of no use allowing bunches of bloom to stand. All the strength of the roots go into the fruit that is tolerably well advanced.

Cucumbers.—Regulated and trained young plants in a pit where fire heat can be given, and thinned considerably those bearing, but becoming the worse of the work they have done. Potted others into 6 and 8-inch pots, to plant them out for winter work if wanted, but for this we have no place very suitable, as our pit is too flat, and the plants receive too little direct light in winter. After February the matter is different. A steep lean-to, or a rather steep span, is best for Cucumbers in winter.

Dwarf Kidney Beans.—Gave a good watering to those which have just come up in a pit, to be treated with a little heat when wanted. Sowed some dozens of large pots out of doors, which pots may be removed under protection when the weather threatens to be cold, and we will sow again shortly. The plants thus raised out of doors in a warm autumn generally do better when housed in time than those sown under glass at once, and they enable us to use the stage a little longer for other purposes.

The weather has become warmer after the delightful rain on the nights of the 18th and 19th, which came just when it was needed, and has made all fresh-planted subjects lift up their heads nicely; even the wasps have become a little torpid over it. In mild damp weather extra care must be taken of young Lettuces, Cauliflowers, &c., otherwise the trouble of planting might be saved. Wood ashes mixed with rough coal ashes are together very annoying to all the slimy tribe; but when very numerous, nothing beats a little heap of brewers' grains mixed with a little bran. We may here mention that though we have seen few dead mice, yet since we put the poisoned grain in the middle of the drain tiles, they have ceased to cut up our plants as they were doing wholesale. The drain tiles are so small, that nothing except mice and small rats could find their way

in, and therefore there was no danger of more valued animals reaching the poison. Care, however, should be taken to see that the mice do not pull it out. We have known cases where pheasants and fowls have been poisoned by rats, after eating a portion in a hole, or in any other place deemed safe, pulling a part out and leaving it exposed. Thus we would rather do without poisoning if we could; there is something hateful and repulsive in the whole process. Poisoned grain cannot now be bought, but we presume we can make a little for our own use, and for birds and mice nothing is more effectual than strychnine or nuxvomica, because it kills so quickly and does not torture.

Ants.—"A Reader" has drawn our attention to the many letters and the many modes adverted to in the *Times* and other papers as to the best mode of destroying ants in dwelling houses. We would refer to these letters, and to what has appeared frequently in this Journal, as to the best mode of making them shift their quarters. For killing them off, the following mode is the most effectual with us when we are forced to interfere with the busy workers. Procure from a chemist some arsenic that has not been blackened, as, we presume, in general it must be. Mix that with moist white sugar, place it in a saucer, place two slips of wood across it, from one-eighth to one-quarter of an inch thick, and on these place another saucer reversed, with a weight on it to keep it firm. The ants will enter between the two saucers, and will die as the contents inside disappear. Without poison great numbers may be caught in vessels smeared with treacle or honey.

FRUIT GARDEN.

Strawberries.—Have not yet cleaned all our Strawberries; but this work ought to have been done, to let more light to the crowns, but for the press of other matters. From those in pots removed all runners, so that all the energies of the roots might be directed to the central crown or bud. One reason why we do not wish to have our plants so strong as we once had them is, that when very strong they are apt to make two or three buds instead of one, and these triple crowns seldom do so well as plants with only one crown.

Apples and Pears.—As soon as the weather becomes fine again we must gather the most of these, as though many would be improved by hanging a little longer, a good many would be apt to drop, and thus be good for nothing but for present use. We housed many soft Apples that used to keep with us up to Christmas, but they soon began to go; and a lot of soft ones we therefore left beneath the trees for the wasps and birds, and so far they acted as traps to the wasps, and kept them and birds almost wholly from the better and keeping fruit.

We wish we could do more than we can at present do in respect to removing the late growths from dwarf and pyramidal trees, as the sap is thus more concentrated in the buds. The buds of most trees look plump and maturing well for another season.

Root-pruning.—As soon as the fruit shall have been gathered, and in the case of trees that have borne none and are rather luxuriant, the earlier the roots are cut the better, so as to tell on the fruitfulness next season, and that, root-pruning will do, very much in proportion to the dry sunny character of the autumn. When fruit trees are young and very luxuriant it is often advisable to take up and replant before the leaves have lost all their greenness. In general, with established dwarf trees which bear rather freely little root-pruning will be necessary, and that should be given a little at a time, cutting the roots a little on one side of the tree this season and on the other side in the following season. This once done, and some rotten dung used as mulching every year, the roots will be so encouraged near the surface that little more cutting of them will be necessary.

ORNAMENTAL DEPARTMENT.

In the pleasure grounds the rains have freshened up the beds that were becoming very dry again, and as the beds were picked over the day previously, the rains have not injured the appearance of the sound blooms. There can scarcely be a more melancholy sight than a gay bed of Pelargoniums containing many faded flowers after a heavy rain, and in such a case even the sound blooms look discoloured and miserable. If we could carry it out we would never take a bloom from flower beds except a faded one, and we would never allow faded seeding blooms to remain. In many cases, were there acres of beds, they would have to be gone over every day to have the mansion studded all over with cut flowers, even though windows and doors open on conservatories and flower gardens; but in such a case some large mixed borders should, if possible, be kept for cutting purposes. We have not this kind of lux-

ury ourselves, but we wish it to be set down as a floral axiom, that when flower beds are expected to be the very best, as far as the weather will allow, no blooms should be taken from them so long as they are fresh. When culled over every day, and the best always taken, it is impossible that the beds can be so full and bright as they otherwise would be.

During such heavy rains as we have had, Anriculas should be protected with a sash, and have plenty of air back and front. A fine opportunity has been given for potting Carnations, pricking-out Pinks, Pansies, Daisies, Wallflowers, &c. Many of our Stocks planted out early in spring, and that lost every leaf by the depredations of the fly, are breaking afresh and blooming well. All tender greenhouse plants should now be taken under protection, but allowed plenty of air, and others so placed that a little protection can be given in a cold night.

Calceolarias may still be sown for spring blooming—full directions were lately given; and the seedlings from the first sowing, if they can be handled at all, should now be pricked off and kept in a cool shady place. Owing to the dry heat, a little fly and a semblance of thrips appeared on some of our Cinerarias, but the insects have now taken their leave, or been killed, by placing in a box some bruised laurels inside of the frame in which the plants were set. Repotted the most forward Chinese Primulas, and potted in small pots numbers of young plants to succeed the others in spring. These little plants in 3½ and 4-inch pots, with a large truss of bloom, are very useful for filling vases and baskets, and are in every way superior to cut flowers. A handsome vase in a room, filled with small plants either out of pots or with the pots concealed, will ever be more pleasing than cut flowers, and will involve the sacrifice of far less time.

Pelargoniums that were cut down we will repot in a few days; Younger ones showing bloom for autumn we keep under glass, and give them plenty of air. Ferns and stove plants want an overhauling as soon as we can find time.

Propagation.—We are still busy with bedding plants, and will be so for a few days longer—rather later than we like; but our plants, though flowering abundantly, made less than usual growth in the hot dry weather; and then when growth came, having no spare borders to go to, we were averse to spoil the symmetry of the beds by taking cuttings, however carefully. One reason which is a kind of solace to us for late cuttings, is, that if we had them early they would become too large for the room we could give them in winter. Most of our plants must stand thickly in winter, say 1 inch being allowed to most Pelargoniums, and less to Verbenas, Heliotropes, &c. We have placed most of the stronger-growing Scarlet Pelargoniums in boxes out of doors, and just shaded them a little in the hottest days, and now they hold up their heads to the sun, and are calling for rooting. Most of the Variegated Pelargoniums are in boxes in a cold pit under glass. Our Verbenas, Heliotropes, Ageratums, &c., we have put in pots in the same pit. If a portion of these do not root quickly, we will take them out and give them a little bottom heat with a cool atmosphere. We shall have to move them in about a month at any rate, as they are now in the same pit as that which we generally fill with Calceolaria cuttings, and it will be time enough to take these off then. We think we are just late enough to strike the Heliotropes without heat, but they will do if the weather continue warm. We prefer all these plants to be struck cool—that is, with nothing but the heat of the sun, as they stand rougher treatment all the winter than if they had been made more delicate with bottom heat.

Even in such simple matters adhering to a system is useful. The Variegated Pelargoniums under glass would need little shading; but such cuttings as Verbenas would soon flag in a sunny day, and one point of a good system is never to let a cutting flag if possible. A common shading over the glass is objectionable for two reasons—first, it is liable to be blown off, and the sun causes the cuttings to flag before the mischief is remedied; the second is, that the person who puts the shading on very often forgets to take it off in time, and every hour that shading remains when not wanted just so far militates against the cutting rooting quickly, so as to be able to look more after itself. For these reasons we frequently dulled the under side of the glass with whitened water, and in bright sunshine just dewed the cuttings with a fine-rosed syringe in preference to giving shade, keeping the sashes down to prevent the moisture going off. This season, having some sashes to spare for a few days, we have dulled the outside of the glass, and placed another sash over it for a short time. Under such treatment one element of success is to keep the sashes shut during the day, and

to open them, say by tilting them up half an inch behind, from evening to the time the sun comes on the glass in the morning.

We may also add that in general, and especially after such a dry season as this, plants at all likely to be affected by *thrips* or *green fly*, as Verbenas, Petunias, &c., have the cuttings, all but the bottom end held in the hand, drawn backwards and forwards through tobacco water, or something of that kind, before inserting them. This little trouble at first often saves much trouble afterwards. If the cuttings are at all badly affected, we let them be for an hour or two after this bath, and then draw them through clean water at 130° before inserting them.—R. F.

COVENT GARDEN MARKET.—SEPTEMBER 23.

PRICES much the same as last week. The supply of Peaches is falling off, also that of Plums; but vegetables are more plentiful.

TRADE CATALOGUES RECEIVED.

G. Jackman & Son, Woking, Surrey.—*Catalogue of Plants.*
 E. G. Henderson & Son, Wellington Road, St. John's Wood, London, N.W.—*Autumn Catalogue of Bulbs, Flower Roots, Greenhouse and Stove Plants, Roses, Fruit Trees, &c.*
 Fisher, Holmes & Co., Handsworth, near Sheffield, 98, Fruit Market, Sheffield, and Market Place, Rotherham.—*Catalogue of Imported Dutch and other Flower Roots.*
 W. Hooper, New Wandsworth, London, S.W.—*Catalogue of Dutch Bulbs and other Flower Roots.*
 Giles & Pascoe, Grove Hill Nursery, and 12, Hindley Street, Adelaide.—*General Catalogue of Trees, Plants, and Shrubs.*

TO CORRESPONDENTS.

BOOKS (*Cleared*).—Williams's "Orchid-Grower's Manual." There is none with coloured plates except at a very high price. (W. Smith).—We believe the work you name is out of print.

PLUM TREE OVERHANGING A NEIGHBOUR'S GARDEN (*An Old Subscriber*).—Ask the owner to cut off the branches which extend so low, and 5 yards over your ground. If he neglect or refuse to remove them, tell your attorney to give him a legal notice to do so, and to take the necessary steps for compelling him to remove them.

CALCAREOUS LOAM (*H. B.*).—It is a mixture of chalk and earth. It is sometimes called marl.

RHUBARB FORCING FOR MARCH CUTTING (*I. H. D.*).—To have Rhubarb in March in a greenhouse the plants should be placed in the house at the beginning of February, and you will have stalks fit to gather in about a month. To have Rhubarb fine a temperature of from 50° to 60° is necessary, it will then be fit for use in three weeks. This temperature, however, would very much injure the greenhouse plants.

SOWING VERBENA AND HELOTROPE SEED (*Idem*).—To have strong plants well hardened-off by May, the seed should be sown from the middle of February to the beginning of March, in a mild hothed, and well hardened-off before planting out.

FLOWERLESS PLANTS (*A Lady in Cheshire*).—No plant produces seeds unless it has flowered previously. We speak of plants generally. The Fungi and other cryptogamic plants have a peculiar reproductive system. Some plants have female flowers and male flowers. The female flowers bear the seed. The Cucumber and Melon are familiar examples. The plant you enclosed is the *Datura stramonium*, or common Thorn Apple.

TACSONIA VAN-VOLXEMI NOT FLOWERING (*Doveholes*).—Your plant is not old enough to flower. It will no doubt do so next season if you now keep it dry at the roots, and expose it fully to light to secure the ripening of the wood. The soil should not be kept so dry, however, as to cause the wood to shrivel. Before growth commences cut the side shoots back to within two or three buds of the main branch, and from the eyes or buds left you may have flowering shoots. The soil should be kept rather dry during the winter. Your soil is suitable, but we should prefer two-thirds loam from turf, one-third leaf mould, and a free admixture of silver sand. The drainage must be efficient. It is well to place a layer of gravel on the shelves for the pots to stand on. The points of the shoots damp off from want of air and heat.

CLIMBERS AND SHRUBS FOR A SOUTH-ASPECT WALL (*E. M. B. A.*).—Your wall with a south aspect will suit White Jasmine, *Ceanothus dentatus*, *Wistaria sinensis*, also *Lonicera anreo-reticulata*, *Clematis Jackmanni*, *C. lanuginosa*, *Berberidopsis corallina*, *Chimonanthus grandiflorus*, *Escallonia macrantha*, *Garrya elliptica*, and *Magnolia grandiflora*. Of Roses, *Maréchal Niel*, *Gloire de Dijon*, *Climbing Devonensis*, *Niphetos*, *Gloire de Bordeaux*, *Celine Forestier*, *Opbirie*, *Solfaterre*, *Lamarque*, and *Cloth of Gold*.

GRUBS DESTROYING PHIMULAS (*W. M.*).—There can be no doubt of the grubs being the cause of the mischief. It is an unusual occurrence, and one for which we cannot suggest any other remedy than to turn the plants out of the pots, and examine the soil and plants by taking away the former from the stems. A few good waterings with soot water would make the grubs uncomfortable, and deluging the pot with lime water would probably destroy them. A little soot sprinkled about the stem would be distasteful to them. Soot water may be made by pouring over a peck of soot thirty gallons of water, and stirring well up previous to use.

FERNS INFESTED WITH INSECTS (*E. F.*).—The insects are aphides, which may be destroyed by fumigating with tobacco, by using a solution of 1 oz. of Clarke's Insect-destroying Compound in a gallon of water, or by tobacco water, either by immersing the plants or syringing them. The *Gnidiads* are subject to red spider, but it yields to a 2-oz. solution of the above-named compound to a gallon of water. There is no means of entirely preventing attacks of insects, but they may be kept down by preventive measures, as a moist atmosphere, and supplying the plants with plenty of water in the case of red spider.

SUNDAY WORK (*Master and Servant*).—You seem to have plenty; but much depends on the style of gardening and the occasional help, and these are matters that no one not personally conversant with the facts could speak with certainty upon. As to what your employer says about a greenhouse being a matter of pleasure, he is no doubt correct, as much of the gardening of the present day is more a matter of luxury than of absolute necessity. What we stated formerly still holds true. The man who entertains strong views on these subjects should not take to a profession where these views are likely to be rather often crossed. Your case so far differs from that of our other correspondent, as your employer seems to wish to have little or no watering done on Sunday, whilst you contend you have so much work on the other days of the week, that you must water on that day. Well, if the work must be done, we would make an effort to do extra watering on Saturday afternoon, so as to do as little as possible on Sunday. We imagine this would suit servant and master.

GRAPES SHANKED—FIGS FALLING (*A Subscriber, Park Street*).—The berries of the Grapes were shanked—that is, the stalk of the berry had withered up. This is chiefly owing to two causes—first, over-cropping; and if this is the case, the fruit is rarely well coloured. The chief cause, however, is the roots being too deep and in an unhealthy state. If the latter, good drainage and even lifting the roots may be necessary. Much good is often effected by securing good drainage and covering the border in winter, so as to keep rain and snow out of the border. The roots are then encouraged to rise naturally. The Figs on your trees out of doors now will do no good, as every one of the size sent will drop in winter. What will stand the winter should not now be larger than small pease. All these Figs had better be cut off with a sharp knife, not pulled off. With fire heat they might ripen, not otherwise. Their presence in such numbers proves that the Fig tree is fruitful, and most likely the falling of the first crop would be prevented by waterings and mulchings after the end of May. If that do not answer let us know next year. The sooner this fruit is cut off the better the chance for next year.

GLAZING A PEACH WALL (*A Constant Reader*).—Such a wall would look well covered with upright sashes 6 feet from the wall, and then a small span roof resting on the wall on one side, and on the plate above the sashes on the other. Where room is an object, we would make a lean-to house, with a height in front of from 3½ to 4½ feet, have ventilators in the front wall and along the apex, if not through the back wall. The trees on the back wall will thrive well, and there is all the enclosed space for general purposes, say 11 feet from the back wall.

HEATING A SMALL GREENHOUSE (*A Subscriber*).—For such a small house, on the score of economy, we would prefer a flue to a boiler, and one of the best modes of having the flue would be to have it below the floor, so that the tile covering would form part of the flue. For cleanliness, however, the hot water would be best, and a saddle boiler of a small size, say 20 inches by 14, by 14, costing about 50s., would suit you. You would need about 90 feet of 4-inch piping. We are in doubt as to your second question, as we do not know whether the word is pointing or painting. For pointing a wall, the best lime should be obtained, and this, bright clean sand, and a little fine-sifted coal ashes beaten into a mortar with as little water as possible. This will stand well. For painting we would use anticorrosion paint of the colour that pleases you best, and before using it the wall should be well scrubbed and then whitened thinly with quicklime wash, which will destroy all green spots, and that should, after standing a few days, be roughly scrubbed off again before applying the paint. From such a general house as referred to, you may have plenty of Grapes, say from the end of August, and yet keep all your plants in winter.

EARLY PEAR—EVERGREEN SCREEN (*J. Y.*).—The Little Muscat is the very early yellow Pear you refer to. It could be obtained for you by any nurseryman. To cover your south wooden fence we would plant Irish Ivy and Cotonaster Simmonsii.

NEWINGTON'S GLASS SCREENS (*R. J. S.*).—Write to Messrs. Rivers, Nurseries, Sawbridgeworth.

ICE STONE (*W. K.*).—If you enclose four postage stamps with your

address, and order No. 348 of our Journal, you will in that see a plan which we think will suit you.

FLOWER-BED PLANTING (*J. C.*).—Your central Rhododendron bed will spoil the effect of the other beds round it when grouped. The best plan to adopt with it would be to plant *Gladioli* amongst the Rhododendrons, and then surround the bed with a belt of a white variegated *Pelargonium*, as *Alma*, *Bijon*, &c. Then your two small circles might be yellow *Calceolarias*, bordered with blue *Lobelia*. As you wish chiefly to have *Pelargoniums*, we would fill two of the long beds crosswise with a dwarf scarlet *Pelargonium*, as *Tom Thumb* or *Little David*, and belt with *Golden Chain*; and two others we would fill with *Mrs. Pollock* or *Cloth of Gold*, or some of Mr. Willis's best bicolors and bronzes, and edge with *Verbena Maconetti*; or, if a *Pelargonium* should be preferred, then use *Harry Hieover*, a little scarlet variety, but the *Verbena* would have the best effect.

INTERIOR OF CONSERVATORY (*A.*).—In such a position, opening into a drawing-room, we would have no stakes at all, but eight or ten ornamental vases or watertight baskets, in which we would set flowering plants, and replace with fresh as they faded. The vases could be draped with dwarf climbers planted out, leaving a hole in the centre to receive the plant, to be moved when the beauty waned, and all covered with a green carpeting of moss. No seeds reached us, but the bit of leaf and a small piece of a yellow flower lead us to think that you have *Cassia corymbosa*, a very useful plant for a cool stove or greenhouse, and even for the open air from the end of May to the middle of October.

PELARGONIUMS, DOUBLE WHITE AND YELLOW (*H. W.*).—There is not a double white *Pelargonium* proper, but there is a neat semi-double *Pelargonium*, known under the name of *Album plenum*. There is also another in the same section, but much larger, with crimson and rose flowers. The above are very interesting varieties, and there is no doubt a fine race of double-flowering varieties of this section will be produced from them. There is, however, no chance of there ever being any hybrids produced between this section and the Zonal kinds, and none of those named in your letter will be of any use for this purpose, as they are quite a distinct race. There is no yellow *Pelargonium* that will answer the purpose you have in view. We have for many years been trying experiments with the view of producing a yellow bedding *Pelargonium*, but with no great amount of success. This season, however, we have many shades very nearly approaching to yellow, and think it is not impossible to produce a yellow in the course of another year or two. A good yellow-flowered bedding *Pelargonium* would be one of the most useful and greatest novelties that could be produced, as the permanency of the yellow *Calceolaria* for this purpose is now so little to be depended on.

RENDLE'S TANK HEATING (*F. J.*).—The tank, 5½ feet by 2½ feet, will keep the frost out of a house 12 feet by 8 feet, if the water in the tank is hot enough. The covering of house slates might not do in winter if laid on loosely, as the steam would pass through too freely, but you could mortar or cement the joint, or cover with one piece of slate. Of course, made as your tank is, you must depend on the heat thrown off by the slate, which, therefore, must be uncovered, or rather exposed when you want a rather dry heat in winter. You must, therefore, have the cold weather past before you can use that tank with a frame over it for propagating purposes, as when you set the frame on you shut in the heat, and prevent its escaping freely into the house; and the sides of the tank being of wood, little heat will come from them. Having the boiler and pipes from it to this tank, we would have a couple of pipes for the house, independently of the tank, and then you could use the latter for propagating as early as you liked. With no more heat in the house it would scarcely be safe to cover it over with your frame until March. The size of the pots in which to winter bedding *Pelargoniums* must depend on the room you have for storage. We keep thousands, allowing merely 1 inch each, in shallow boxes, as we could find room in no other way. The plants which you now have well rooted and established in 2½ to 3-inch pots, will stand the winter well in those pots; but if you have plenty of room, the plants will be much finer in spring if you can now transfer them to 4½-inch pots, and the sooner it is done the better.

HYACINTHS AND CROCUSES (*A. Y. E.*).—You may grow them in common mould mixed with sand, or even in sand alone, provided you keep them duly supplied with water.

FRUIT TREES FOR WALLS (*W. B. R.*).—The wall, B, in your plan will have a south-east aspect, and will be suitable for Plums. On it you may have *July Green* Gage, *Green Gage*, *Kirk's*, *Jefferson*, and *Coe's Golden Drop*. The wall, A, will have an east aspect with a northerly bearing, and will be suitable for Apples: *Red Astrachan*, *Cellini*, *Claygate Pearmain*, *King of the Pippins*, *Cockle Pippin*, and *Scarlet Nonpareil* will be suitable. C, will answer for Pears, of which you may have *Beurré Diel*, *Marie Louise*, *Bergamotte Espere*, *Glen Morgeau*, and *Ne Plus Meuris*.

APPLES FOR ORCHARD (*Idem*).—*Dessert*: *Devonshire Quarrenden*, *Kerry Pippin*, *Margil*, *Court of Wick*, *Downton Pippin*, and *Wyken Pippin*. *Kitchen kinds*: *Lord Suffield*, *Keswick Codlin*, *Alfriston*, *Dumelow's Seedling*, *Northern Greening*, and *Bedfordshire Foundling*.

PICTURES, CARNATION, AND PINK PIPINGS FAILING (*J. Y.*).—We cannot perceive anything wrong with the piping sent, only it appears to have been drawn. We prefer to cut the piping with a sharp knife immediately under the second or third joint, and remove the lowest pair of leaves. Drawing answers well enough for Pinks, but we consider cutting better for Carnations and Pictories. For the last two, make a slight hotbed of well-sweetened dung about 2 feet high, and cover with about 6 inches of sandy loam and leaf mould. The pipings should be inserted from three-quarters of an inch to an inch deep, the soil made firm about them, and a gentle watering given. When the foliage has dried, cover them with hand-glasses or a frame and lights. Keep them close and shaded from the sun, but if any of the pipings suffer from damp a little air must be given, all decayed leaves being picked off. Dryness must be guarded against, a gentle watering being given whenever necessary, taking care to let the foliage be dry before the lights are again closed. When the pipings grow they will have rooted, and air may be gradually admitted and the plants by degrees hardened off. Pinks are treated in the same manner as the Carnation, only heat is not necessary, though it renders striking more certain, but it is desirable to cover the pipings with a hand-glass. Your pipings perish from exhaustion by the atmosphere, and the "very moist" soil is not good. It should be moist, that is all.

ARBOR-VITE FROM CUTTINGS (*Reader*).—The *Arbor-Vite* may be propagated from cuttings, but the best plants are those from seed. The end of August or beginning of September is the best time to put in the cut-

tings, taking the points of the growing shoots when they have become somewhat ripened. They will be rooted in from six to eight weeks. For further particulars see page 174 of No. 388. Your other questions will be answered next week.

FILLING CROCUS HOLDERS (*Ignoramus*).—No time should be lost in putting in the Crocuses. The best and only way that we know of filling them is to invert the holders, and place a Crocus opposite each hole in the holder, and so that the foliage and flowers will come through the hole. You may then put in some soil composed of two-thirds loam and one-third leaf mould or old rotten manure, adding more Crocuses when the soil is level, or nearly so, with the next tier of holes, and in this manner proceed until the holder is filled. The soil should be pressed firm; it is well that it should not settle much.

OLEA FRAGRANS CULTURE (*J. W.*).—It should be treated as a cool greenhouse plant, and succeeds under the same treatment as Camellias—that is, as regards heat, &c. Care should be taken to secure a well-formed plant by frequently pinching back and regulating the shoots. After a specimen is formed and the flowering is past, any pruning required should then be done, and the plant be potted if needed, keeping it rather close for a few days until the roots are working freely in the fresh soil. Secure a good growth by preserving a moist atmosphere, and by stepping the irregular shoots maintain the shape of the plant. After a good growth has been made expose the plant fully to light and admit abundance of air, keeping the soil moderately dry during the winter, but not so dry as to affect the foliage. It is propagated by layers, also by cuttings of the half-ripened wood in a hotbed. A compost of turfy loam two-thirds, and one-third sandy peat will grow it well.

PALMS for Rooms (*Salopian*).—What we stated at page 186, and a communication which we publish to-day, afford all the information we have on the subject at present.

DAHLIA IMPERIALIS.—"J. W." wishes to know if this has been bloomed here, and, if so, when? also if there is more than one kind. All that we know about this flower is stated fully in our fourteenth volume.

NAMES OF FRUITS (*W. Collier*).—1, Calville rouge d'Élé; 2, Tower of Glammis. (*W. B.*)—Easter Beurre Pear, an excellent late dessert variety, but in some situations and in some seasons it is difficult to ripen it thoroughly. The other fruit is Haeon's Incomparable. (*S.*, *Thirsk*).—Apples: 1, Unknown; 2, Rymer. (*G. T. M.*)—Pears: 1, Duchesse d'Angoulême; 2, Easter Beurre; 3, Old Colmar; 4, Unknown. (*Amateur*).—The Apple is unknown, it is most probably a seedling, but of no great value. We have had submitted to us frequently, Apples very similar to yours, from old orchards throughout the country. Irrespective of its size it is, in our opinion, very deficient in flavour. We do not think that the difference in the mode of training will make much difference as to the bearing properties.

NAMES OF PLANTS (*H. Ventnor*).—Your shrub is the Scarlet-berried Thorn, *Crataegus coccinea*. The French name for it is *Azerolier*. (*C. Thompson*).—*Linaria purpurea*. (*J. A. K.*)—*Segeta cæsia*; *Lythrum virgatum*, *Fuchsia*, apparently *F. Loxensis*. (*H. T. W.*)—1, *Scalagnella Kraussiana* (*S. denticulata* of gardens); 2, *Spiraea aruncus*; 3, *Blechnum bogneri*; 4, *Adiantum formosum*. (*A. Reid*).—*Tecoma jasminoides*. (*A. Bogner*).—*Hedychium coronarium*. (*Novice*).—*Hedychium Garancinum*; will thrive in a greenhouse. (*C. P.*)—Not recognised. Send a better specimen.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the week ending September 22nd.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

OTHER BANTAMS THAN GAME BANTAMS.

EVERY man has his hobby, and the breeding of Bantams is mine; but I prefer the comparatively peaceably disposed kinds, and am sometimes led to wonder how it is that those of a more pugnacious character have obtained such an ascendancy in the poultry world. Sometimes I am hurt, sometimes I am angry, at finding the exquisite little Game bird put at such an immeasurable distance above the not less exquisite Sebright, Black, White, or Japanese.

Tastes will differ, and upon the whole, perhaps (at any rate in the eyes of some people), the various races of Game possess the greatest number of points of attraction; but surely the difference is not so great as is implied in some of the poultry show schedules lately issued. Take the Birmingham prize list. I have always regarded Bingley Hall as the place where every description of fowl received its fair share of attention and reward; but this year I regret to say I am compelled to alter my opinion, since justice to my especial hobby has departed. The prizes offered to any variety of Bantams except Game have been reduced from £27 to £17; those for the various Game breeds remaining about the same as in former years—viz., £30. Now, in the name of my snubbed and slighted favourites I protest against this unjust treatment; and I have resolved that only half the number of voices which I contemplated sending from my yard shall be heard this year at the Great Show. As to Manchester, it actually insults Bantam breeders by offering £6 in prizes for "all varieties except Game," while the Game birds have £44 awarded to their different classes! Surely this is unreasonable, and such short-sighted parsimony will defeat its own object; for who will send valuable birds any distance on such a speculation? Certainly not your obedient servant—P. P.

THE MANCHESTER PRIZE LIST.

We quite agree with the remarks of Mr. Heath, in last week's Journal, regarding the time of holding the Manchester Poultry and Pigeon Show, but hope with such a liberal prize list the Show will meet with the same success that has attended

it in former years. Still, we think that for a chicken show it is at least six weeks too early. Birmingham will be quite early enough, and had Mr. Jennison held his show two or three weeks after the great poultry show of the year, birds would have been in better plumage, consequently the entries would be more numerous. Mr. Heath justly observes that Spanish are slow in feathering, they also have the disadvantage of other breeds, so much depending on the white face and lobes, which do not come out prominently until the birds are in feather, especially pullets; therefore, unless hatched in January, or at latest February, they cannot be ready for Manchester.

We have stated the prize list is liberal, almost too liberal in some classes. We refer to the prizes for Bantams, in which Game are offered £44, whilst all the other varieties are cut off with £6. Is this fair, with the same entry fees? We think if Mr. Jennison had offered a separate class for Black and White Bantams, he would have found the entries more numerous than in some of the Game Bantam classes. If he did not think Sebrights would pay for a class, he could let them fight it out with the Pekins, Japanese, &c. Although we believe Sebright would also pay for a class to themselves, we do not think the foreigners would pay, as they have never been out of the hands of some half dozen gentlemen; and it is certainly not right they should walk over those birds which have the legitimate right to the prizes, not only on account of their numerous entries, but for the length of time they have been known and bred by so large a number of fanciers. We all know the great weakness of judges for foreign varieties, so would, therefore, respectfully ask the Committees of Manchester, and other shows as well, to give the old Black, White, and Sebright Bantams, separate classes, and we feel sure they will find them pay.—TOKIN AND TUCKER, Bristol.

DERBY POULTRY SHOW.

It is quite certain that previous shows of poultry and Pigeons, held in connection with the Derbyshire Agricultural and Horticultural Society, have surpassed that which took place on the 16th inst. There appears to be a dearth of first-rate chickens this year throughout the country, possibly from the excessive heat of the late summer, and as just now most poultry are in heavy moult, very few birds can be shown to anything like advantage. The *Dorkings* exhibited by Mrs. Arkwright were, however, extraordinarily fine specimens, as were some other pens in the same class; but the *Spanish* were so bad, that not

even a single prize could be awarded to them. We were also much disappointed in the *Hamburgh* classes, for which this Show is usually in great repute, the falling-off being remarkable this year. A few good pens of *Game* were shown, but there was not a large competition.

The *Duck*, *Geese*, and *Turkey* classes were good. A very curious bird, a *Darling* hen that had entirely assumed the plumage of the cock, attracted much attention. The Show, as to attendance, was successful.

YOUNG BIRDS.

DORKINGS (Coloured).—First and Second, Mrs. Arkwright, Etwell Hall. Highly Commended, A. F. Hart, Alderwasley; Countess of Chesterfield, Brethly Hall.

DORKINGS (White).—First, Withheld. Second, G. J. Mitchell, Newton Mount.

GAME (Dark-breasted).—First, C. Spencer, Thulston. Second and Highly Commended, G. J. Mitchell.

GAME (White or Pile).—First and Second, C. Spencer. Highly Commended, E. Canner, Stanley.

HAMBURGS (Gold-pencilled).—First and Second, A. O. Worthington, Commended, C. Spencer.

HAMBURGS (Silver-pencilled).—First and Second, H. King, Melbourne.

HAMBURGS (Silver-spangled).—First, G. J. Mitchell, Second, Countess of Chesterfield.

COCHIN-CHINAS.—First, J. B. Story, Lockington. Extra First, R. Radford Aston-on-Trent. Second, A. O. Worthington. Highly Commended, G. A. Crewe, Etwell; W. P. Tomlinson, Allestree. Commended, R. Radford.

BRAMMAS (Light).—First and Second, A. O. Worthington. Highly Commended, W. Pares, Ockbrook.

BRAMMAS (Dark).—First and Second, Rev. E. Alder, Etwell. Highly Commended, A. F. Hart, Alderwasley.

CROSS-BRED.—First, Rev. E. Alder. Second, G. J. Mitchell.

DUCKS (Rouen).—First, A. F. Hart. Second, A. O. Worthington.

DUCKS (Aylesbury).—First, J. B. Story, Lockington. Second, A. O. Worthington. Highly Commended, G. J. Mitchell; G. A. Crewe; A. O. Worthington. Commended, W. Pares.

GEES.—First, W. T. Cox, Spendon Hall. Second, J. Nuttall, Chaddean.

TURKEYS.—First, G. J. Mitchell. Second, A. O. Worthington. Extra.—Highly Commended, T. H. Smith, Amboston.

SPECIAL.—First, A. O. Worthington. Second, Mrs. Arkwright. Highly Commended, Countess of Chesterfield; G. A. Crewe.

PIGEONS.

ROCK OR DOVECOTE.—First, T. L. Harrison, Belper. Second, G. J. Mitchell.

ANTWERP OR BELGIANS.—First, G. Haywood, Derby. Second, J. Langley, Mickleover.

TUMBLERS.—First, Second, and Commended, T. L. Harrison, Belper.

FANTAILS.—First, G. Haywood. Second, F. Sale. Highly Commended, A. O. Worthington.

ANY OTHER DISTINCT VARIETY.—First, G. Haywood (Blue Turbitts). Second, Rev. E. Alder, Etwell (Silver Runts). Highly Commended, F. Sales (Black Swallows, Red Turbitts, English Silver Owls, and Black Magpies); T. L. Harrison (Foreign Owls, Blue Turbitts, and Silver English Owls); G. A. Crewe (White Carriers); J. W. Eardley, Derby (Blue Dragons).

The Judges were Edward Drewry, Esq., Barton-on-Trent; J. Lowe, Esq., of Comberford; and Edward Hewitt, Esq., of Birmingham.

MORLEY POULTRY SHOW.

UNDER rather unfavourable auspices so far as the weather was concerned, the Morley Show was held on the 18th inst. There was, however, an excellent display of birds. *Cochins* were very numerous, and contained some first-rate pens. *Game* showed no less than twenty-nine entries, the cup going to a pen of Black Reds, while Mr. Mason, of Drighlington, exhibited some magnificent Pile chickens in the Any variety class. *Hamburghs* were the feature of the show; as last year, the cup went to the Gold-pencilled, Mr. Preston, of Allerton, Bradford, one of the best breeders of Pencilled *Hamburghs* in the county, being its fortunate possessor. Both Gold and Silver-spangled were rather numerous, and here, too, some good birds came into competition. *Bantams* were very numerous. In *Geese* Mr. Leech, of Rochdale, took the cup against nine competitors.

Pigeons were a good show, the competition in *Barbs* and *Jacobins* being very strong. The following is the prize list:—

SPANISH.—First and Cup, J. Thrash, Bradford (Black). Second, T. C. and E. Newbitt, Epworth.

DORKINGS.—First, W. H. King, Sandfield, Rochdale. Second, J. B. Britton, Leeds Pottery.

COCHIN-CHINA.—First, J. W. Wilkinson, Bradford. Second, T. Stretch, Ormskirk.

BRAMA-POOTRA.—First, E. Leech, Rochdale. Second, J. W. Wilkinson, GAME (Black-breasted Reds).—First and Cup for best pen of Game, H. Jennings, Allerton. Second, G. Noble, Stinchfield.

GAME (Brown-breasted or other Reds).—First, W. Bentley, Scholes. Second, E. Aykroyd, Bradford.

GAME (Duckwings or other Greys and Blues).—First, W. Fell, Adwalton. Second, R. B. Riley, Ovenden.

ANY OTHER VARIETY.—First and Second, H. Mason, Drighlington.

SINGLE GAME COCK (Any variety).—First, H. Mason. Second, Green and Sutcliffe, Queensbury, near Halifax. Third, H. Jennings. Fourth, E. Aykroyd, Bradford.

SINGLE GAME HEN (Any variety).—First, J. Preston, Allerton. Second, G. Noble.

HAMBURGH (Golden-spangled).—First, J. Preston. Second, J. White, Whitley Netherthorpe, near Wakefield.

HAMBURGH (Silver-spangled).—First, T. Fawcett, Northgate, Baildon. Second, W. Collins, Halifax.

HAMBURGH (Golden-pencilled).—First and Cup, J. Preston. Second, S. Smith.

HAMBURGH (Silver-pencilled).—First, T. Hansen, Keighley. Second, W. Barstow, Fearncliffe, Bingley.

HAMBURGH (Black).—First, J. Preston. Second, C. Sidgwick, Keighley.

ANY OTHER VARIETY NOT PREVIOUSLY MENTIONED.—First, J. S. Senior, Dewsbury. Second, T. Deans, Keighley.

BANTAMS.—First, G. Noble, Stinchfield. Second, F. Steel, Halifax.

BANTAMS (Black).—First, R. B. Riley, Ovenden, near Halifax. Second, S. & R. Ashton, Mottum.

BANTAMS (Any other variety).—First, J. S. Senior, Dewsbury. Second, S. & R. Ashton.

SELLING CLASS.—First, J. Berry, Silsden. Second, J. W. Wilkinson.

GESE (Any variety).—First, Cup, and Second, E. Leech. Third, S. H. Stott, Rochdale.

DUCKS (Rouen).—First, E. Leech. Second, J. Ward, Drighlington.

DUCKS (Aylesbury).—First, S. H. Stott. Second, E. Leech.

DUCKS (Any other variety).—First, S. Burn, Whithy (India). Second, T. C. Harrison, Hull.

PIGEONS.

CARRIERS.—First, E. Horner, Harewood. Second, R. Wilson, Thirsk.

OWLS.—First, H. Yardley, Birmingham. Second, J. Thrash, Bradford.

TURBITS.—First, J. T. Fishman, Bradford. Second, E. Horner.

BARBS.—First and Second, E. Horner.

TUMBLERS.—First, T. C. & E. Newbitt, Epworth. Second, D. W. Ing-ham, Thornhill, Wortley.

FANTAILS.—First, T. C. & E. Newbitt. Second, E. Horner.

POUTERS.—First, E. Horner. Second, T. C. & E. Newbitt.

NUNS.—First, J. A. Naylor, Barwick-in-Elmet. Second, J. Thompson, Bingley.

JACOBINS.—First, E. Horner. Second, J. Thompson.

TRUMPETERS.—First, E. Horner. Second, R. Wilson.

ANY OTHER VARIETY.—First, T. C. & E. Newbitt. Second, J. S. Senior.

The Judges were Mr. Henry Mitchell, of Hipperholme, and Mr. Alfred Hardy, of Wike.

WIRRAL AGRICULTURAL SOCIETY'S POULTRY SHOW.

THIS was held on the 16th inst., at Birkenhead, and proved a very successful exhibition.

The following is a list of the awards:—

DORKINGS.—First, R. W. Beachey, Kingskerswell. Second, Lord Turnour, Chilling, Petworth, Sussex. Third, J. G. Bull, Bromborough. Commended, J. P. Campbell, Burton Hall, Neston.

SPANISH (Black).—First, W. A. Taylor, Manchester. Second, T. & E. Comber, Middleton Hall, near Warrington. Highly Commended, R. Davies, Chester.

GAME.—First, J. Wood, Wigan. Second, W. Berry, Birkenhead. Third, W. Boulton, Dalton-in-Furness. Highly Commended, A. C. Lockwood, Chester.

COCHIN-CHINA.—First and Third, W. A. Taylor. Second, R. E. Brown, Wassa, Oswaldkirk. Commended, A. Darby, Stanley Hall, Bridgworth; B. S. Lowndes, Stony Stratford, Bucks.

BRAMA POOTRA.—First, C. Leyland, Warrington. Second, E. Leech, Rochdale. Commended, A. C. Lockwood.

ANY OTHER BREED.—First and Third, T. & E. Comber. Second, G. R. Rogerson, Liverpool.

GAME BANTAMS.—First, W. Berry, Bidston Hill Tollbar. Second, R. Barton, Caldy Manor.

DUCKS (Aylesbury).—Prize, E. Leech.

DUCKS (Rouen).—First, Miss Davies, Chester. Second, S. H. Stott, Rochdale.

DUCKS (Any other breed).—First, C. N. Baker, Chelsea. Highly Commended, J. Woods, Thornton Hough.

GESE.—Second, E. Leech. Third, S. H. Stott. Highly Commended R. Birch, jun., Orrell, Liverpool; J. P. Campbell.

TURKEYS.—First, E. Leech. Second, J. Wood, Wigan. Third, J. P. Campbell.

The Judges for poultry were Mr. Hindson and Mr. Joseph Cox.

WOODSTOCK POULTRY SHOW.

THIS Show was held on the 15th inst., was good, and there were more entries than previously, but the quality was not quite so fine.

SPANISH.—Prize, R. Hurman, Oxford.

DORKINGS (Coloured).—First and Third, Duchess of Marlborough. Second, Col. Thomas, Woodstock. *Chickens.*—Prize, Duchess of Marlborough, Etenheim.

BRAMMAS.—Prize, Duchess of Marlborough. *Chickens.*—Prize, Col. Thomas.

COCHIN-CHINA.—Prize, R. Hurman.

HAMBURGH (Spangled).—Second, R. Hurman.

HAMBURGH (Pencilled).—Second, Mrs. Aries, Thrapp. *Chickens.*—Second Mrs. Aries.

GESE.—Prize, J. Hunt, Thrapp. *Chickens.*—Prize, J. Hunt.

GESE (White).—First, J. Prior, Thrapp Farm, Shipton. Second, — Saunders.

GESE (Grey).—First, Duchess of Marlborough. Second, H. S. Gaskell, Kidlington Hall. *Goosings.*—First, H. Barnett, Glympton Park. Second, Duchess of Marlborough.

DUCKS (Aylesbury).—Prize, Duchess of Marlborough. *Ducklings.*—First, H. S. Gaskell. Second, Duchess of Marlborough.

DUCKS (Rouen).—Prize, J. Hunt. *Ducklings.*—Second, J. Hunt.

DUCKS (Any other variety).—Prize, T. Sester. *Ducklings.*—First, T. R. Pratt, Woodstock. Second, T. Lester, Glympton.

TURKEYS (Black).—Prize, Duchess of Marlborough. *Poult.*—First, J. Prior. Second, Col. Bowyer, Steple Ashton.

TURKEYS (Grey).—Prize, Duchess of Marlborough. *Poult.*—First, Col. Bowyer. Second, Duchess of Marlborough.

SPECIAL PRIZE (Given by the Duchess of Marlborough).—First, H. Dean, Deddington. Second, J. Hull, Thrapp.

CHAMPION PRIZES (Offered by Holford C. Risley, Esq., President).—First and Second, Duchess of Marlborough.

Mr. G. Botham, Wrexham Court, Slough, was Judge, the Rev. Mr. St. John, Woodstock, assisted him.

MIDDLETON POULTRY SHOW.

THE entries of poultry and Pigeons at this Show, which was held on the 17th inst., were extremely numerous, so much so that a much larger extent of ground had to be enclosed for the purposes of the Exhibition. The following is a list of the awards:—

CHICKENS.

GAME (Black-breasted and other Reds).—First, Duke of Newcastle, Clamber. Second, W. Bourne, Heavily, Stockport. Third, J. Holland, Manchester.

GAME (Any other variety).—First, R. B. Ryley, Jumbles Lodge, Ovenden. Second, J. Fletcher. Third, Duke of Newcastle.

GAME (Any variety).—*Pullets*.—First and Cup, J. Wood, Wigan. Second, H. Mann, Stand, near Manchester. Third, W. Bourne. Fourth, A. Haslem, Hindley, near Wigan. Highly Commended, T. Statter, sen., Whitefield; J. Fletcher; J. Jeken, Eltham. Commended, W. Bourne.

SPANISH.—First, Burch & Boulter, Sheffield. Second, J. Walker, Wolverhampton. Third, H. & S. Cooper, Walsall. *Pullets*.—First, J. Thresh, Bradford. Second, Burch & Boulter.

DORKINGS.—First, Duke of Newcastle. Second, Hon. H. W. Fitzwilliam, Wentworth Woodhouse. Third, J. Stott, Healey. *Pullets*.—First, T. Statter, sen. Second, Mrs. Hurt, Alderwasley, Derby. Highly Commended, H. Ashton, Prestwich; D. Gellatly, Meigs, N.B.; J. White, Northallerton.

BRAMA POOTRA.—First, K. Jopp, Aberdeen. Second, J. Siebel, Timperley. Third, Rev. J. F. Newton, Kirby-in-Cleveland. Highly Commended, C. Layland; W. Hargreaves, Bacup. *Pullets*.—First, Mrs. Hurt. Second, A. G. Worthington, Newton Park, Burton-on-Trent. Highly Commended, G. Dixon, jun., Whitehaven; E. Leech, Rochdale. Commended, K. Jopp; J. Siebel.

COCHIN-CHINA (Buff and Cinnamon).—First, W. A. Taylor, Manchester. Second, J. Lee, Middleton. Third, R. E. Brown, Wals. *Pullets*.—First, Hon. Mrs. Sugden, Wells. Second, C. Sidgwick. Highly Commended, T. Eveleigh, Bolton-le-Moors; W. A. Taylor, Manchester.

COCHIN-CHINA (Any other variety).—First, J. A. Taylor. Second, J. Horrocks, Middleton. Third, A. O. Worthington. *Pullets*.—First, H. Vaughan, Wolverhampton. Second, H. Lingwood, Bucklesham, Woodbridge. Highly Commended, J. A. Taylor; W. Bamford, Moston, Harpurhey; A. O. Worthington.

HAMBURGS (Gold-pencilled).—First, T. Wrigley, Tonge. Second, J. Robinson, Failsworth. Third, W. K. Park, Melrose. Highly Commended, H. Beldon, Goitstock, Bingley. *Pullets*.—First, F. Perriu, Killingbeck, Leeds. Second, W. E. Walker, Middleton.

HAMBURGS (Silver-pencilled).—First, H. Beldon. Second, M. M. Maur, Kendal. Third, F. Sharples, Rawtenstall. *Pullets*.—First, S. Newton, Chadderton. Second, W. & J. Bairstow, Bingley. Highly Commended, H. Pickles, jun., Early.

HAMBURGS (Gold-spangled).—First, J. Buckley, Taunton, near Ashton. Second, J. Chadderton, Hollinwood. Third, E. Brierley, Heywood. Highly Commended, J. Munn, Stacksteads; R. Simpson, Hollinwood; J. Preston, Allerton. *Pullets*.—First, T. Blakeman. Second, T. Scholes, Hollinwood. Commended, W. McMillan, Glossop.

HAMBURGS (Silver-spangled).—First, J. Fielding, Newchurch. Second, H. Pickles, jun. Third, W. H. Robinson. *Pullets*.—First, Ashton & Booth, Mottram. Second, A. Ludlam. Highly Commended, J. Fielding.

HAMBURGS (Black).—First, C. Sidgwick. Second, W. Robinson. Third, G. Fielding, Newchurch. *Pullets*.—First, W. Holt, Middleton. Second, T. Hanson, Castleton. Highly Commended, E. Buckley, Rochdale; Rev. W. Sergeantson, Shrewsbury.

FRENCH FOWLS.—First, Hon. H. W. Fitzwilliam, Wentworth Woodhouse, near Rotherham. Second, Duke of Newcastle. Third, J. K. Fowler, Aylesbury. Highly Commended, L. Biney, Manchester; W. R. Park, Melrose. Commended, Col. Stuart Wortley, London; H. M. Maynard, Holmewood, Isle of Wight. *Pullets*.—First, J. K. Fowler. Second, W. A. Bernel, Southwell. Commended, Col. Stuart Wortley.

ANY OTHER VARIETY.—First, J. S. Senior, Dewsbury. Second, P. Unsworth, Newton-le-Willows. Third, H. Beldon. Highly Commended, R. Loft, Woodmansey, near Beverley; J. K. Fowler. *Pullets*.—First, H. Beldon. Second, S. Farrington, Astley. Highly Commended, P. Unsworth. Commended, Mrs. E. Procter, Hull.

GAME BANTAMS.—First, W. F. Entwistle, Leeds. Second, J. Crosland, jun., Wakefield. Third, J. W. Morris, Rochdale. Highly Commended, J. W. Morris; Rev. G. Raynor; G. Birtwistle. Commended, J. Crosland, jun.; E. Toder.

BANTAMS.—First, S. & R. Ashton, Mottram. Second, E. Cambridge, Bristol. Third, M. Leno, Dunstable. Highly Commended, T. C. Harrison, Hull; Aykroyd & Scott, Sunderland.

SELLING CLASS.—First, W. A. Taylor. Second, A. Bamford, Middleton. Third, J. Lee, Middleton.

DUCKS (Aylesbury).—First, E. Leech, Rochdale. Second, J. K. Fowler. Third, S. H. Stott.

DUCKS (Rouen).—First, E. Leech. Second and Third, T. Statter, sen. Highly Commended, J. J. Waller, Kendal; T. Wakefield.

ANY OTHER VARIETY.—First and Third, C. W. Brierley. Second, T. C. Harrison, Hull.

GEES.—First, T. Houliker, Blackburn. Second, E. Leech. Highly Commended, J. K. Fowler; S. H. Stott.

TURKEYS.—First, T. Houliker. Second, T. E. Richardson, Cambridge.

SINGLE COCKERELS.

GAME (Black-breasted and other Reds).—First, Duke of Newcastle. Second, J. Fletcher, Stoneclough, near Manchester.

GAME (Any other variety).—Prize, T. Dyson, Halifax.

SPANISH.—First, H. & S. Cooper. Second, P. H. Jones, Fnlham.

DORKING.—First, T. Statter, sen., Stand, near Manchester. Second, Hon. H. W. Fitzwilliam.

BRAMA POOTRA.—First, Rev. A. G. Brooke, Ruyton XI. Towns. Se-

cond, A. O. Worthington. Highly Commended, Duke of Newcastle. Commended, H. Pickles, Southport; E. Ryder, Stockport.

COCHIN-CHINA (Buff and Cinnamon).—First, W. A. Taylor. Second, J. C. Brierley, Rochdale. Commended, C. Sidgwick.

COCHIN-CHINA (Any other variety).—First, H. Lingwood. Second, J. A. Taylor. Third, A. O. Worthington.

HAMBURGH (Gold-pencilled).—First, H. Beldon. Second, J. Preston, Allerton, near Bradford. Commended, B. Bee, Bullsnappe Hall.

HAMBURGH (Silver-pencilled).—Prize, W. & J. Bairstow. Highly Commended, F. Sharples.

HAMBURGH (Gold-spangled).—First, J. Munn. Second, T. May, Wolverhampton. Highly Commended, R. Ellis, Saddleworth.

HAMBURGH (Silver-spangled).—First, W. H. Bentley, Hipperholme, near Halifax. Second, H. Pickles, jun.

HAMBURGH (Black).—First, C. Sidgwick. Second, Mason & Walker, Denton.

FRENCH FOWLS.—First, Duke of Newcastle. Second, J. K. Fowler.

ANY OTHER VARIETY.—First, H. Beldon. Second, P. Unsworth.

GAME BANTAMS.—Cup, W. Adams, Ipswich. Second, J. Crosland, jun. Third, J. Bamber, Acerington. Highly Commended, T. Whittaker, Melton Mowbray; J. J. Cousins, Chapel Allerton. Commended, J. W. Morris, Rochdale.

SELLING CLASS.—First, F. Sales, Crowle. Second, W. A. Burnell, Southwell. Highly Commended, J. S. Senior, Dewsbury. Commended, W. A. Buruell; Master W. Horrocks, Middleton.

PIGEONS.

TUMBLERS (Almond).—First, F. Key, Beverley. Second, J. Fielding, jun., Rochdale. Highly Commended, J. Hawley, Bingley.

TUMBLERS (Any other variety).—First, R. Fulton, Deptford. Second, J. Fielding, jun.

BAIDS OR BEARDS.—First, J. Fielding, un. Second, T. Newell, Ashton-under-Lyne.

CARRIERS.—*Cock*.—First, E. Horner, Leeds. Second, Capt. Maignall. Highly Commended, G. F. Taylor, Preston; R. Fulton. *Hen*.—First, J. Hawley. Second, R. Fulton. Highly Commended, and Commended, J. Fielding, jun.

POUTERS.—*Cock*.—First, R. Fulton. Second, J. Hawley. Highly Commended, E. Horner. *Hen*.—First, E. Horner. Second, R. Fulton.

BARBS.—First, E. Horner. Second, R. Fulton. Commended, J. Fielding.

TURBITS.—First, J. Fielding. Second, J. Elgar, Newark. Highly Commended, E. Horner; Capt. Maignall.

JACOBS.—First, E. M. Royds, Rochdale. Second, T. Newell. Highly Commended, E. Horner.

FANTAILS.—First, E. Horner. Second, W. R. Park, Melrose. Highly Commended, E. M. Maynard, Ryde.

OWLS.—First and Second, J. Fielding. Highly Commended, P. H. Jones.

NUSS.—First, W. R. Park. Second, H. Yardley, Birmingham.

DRAGONS.—First, Countess of Derby. Second, T. Charuley, Blackburn. Highly Commended, E. Horner; P. H. Jones; G. Charnley, Preston. Commended, E. Horner.

TRUMPETERS.—First, E. Horner. Second, R. B. Chouler. Commended, E. Horner.

ANY OTHER VARIETY.—First and Second, E. Horner. Commended, Countess of Derby; H. Yardley.

SELLING CLASS (Any variety).—First, B. Carlisle, Blackburn. Second, J. Thompson.

RABBITS (Lop-eared).—First, A. H. Easton, Hull. Second, G. Jones, Birmingham. Highly Commended, F. L. Jones, York. *Angora*.—First, C. Rayson. Second, W. B. Etches. Highly Commended, G. Jones.

Himalayan.—First, T. & A. Schofield, Rochdale. Second, C. Rayson.

Silver-Greys.—First, A. H. Easton. Second, E. M. Royds. Commended, C. Rayson. *Any other variety*.—First, J. Grundy, Bury. Second, C. Rayson. Highly Commended and Commended, F. L. Jones.

JUDGES.—Mr. R. Teebay, Fulwood, Preston, and Mr. W. B. Tegetmeier, Fortis Green, London, for *Spanish, Cochins, Brahmas, Hamburgs, Pigeons and Rabbits*; in the other classes Messrs. Fielding and Martin.

NORTHALLERTON POULTRY SHOW.

WITH a very wet and unfavourable day, this Show, held on the 18th inst, was rather unfortunale. There was an increase in the entries. Of *Hamburgs* there was a good muster, containing some good specimens. *Spanish* were indifferent, while *Cochins* were very good. *Bantams* had no less than thirty entries, while young *Geese* mustered eleven couple. Of *Pigeons*, the show was small.

Subjoined is the prize list:—

DORKINGS.—First, O. A. Young, Driffield. Second, J. White, Warlaby.

GAME.—First and Second, W. Bearpark, Ainderby Steeple.

SPANISH.—First, W. & F. Pickard, Thorne, Leeds. Second, W. Bearpark.

COCHIN-CHINA.—First, R. E. Brown, Oswaldkirk (Buff). Second, W. Barnes, Thirsk.

BRAMA POOTRA.—First, A. Grainger, Thirleby. Second, W. Scrers, Kirby Fletham.

HAMBURGS (Gold-spangled).—First, J. Bell, Thorne-le-Moor. Second, W. Bearpark.

HAMBURGS (Silver-spangled).—First, G. Holmes, Great Driffield. Second, W. Scrers.

HAMBURGS (Gold-pencilled).—First, W. Ainderby. Second, R. Pennington, Market place, Thirsk.

HAMBURGS (Silver-pencilled).—First, O. A. Young, Driffield. Second, T. White, Warlaby.

ANY OTHER DISTINCT VARIETY.—First, G. Carter, Bedale (Polands). Second, J. Fox, Thirsk (Black Hamburgs).

BANTAMS (Any variety).—First, O. A. Young. Second, R. Trueman, Thirsk.

DUCKS (Rouen).—First, J. Mason, Boroughbridge. Second, Mrs. Morton, Leak Hall, Thirsk.

Ducks (Any other variety).—First, M. Harrison, Pocklington (Aylesbury). Second, O. A. Young (Aylesbury).
TURKEYS.—First, J. Braithwaite, Otterington House Farm. Second, Mrs. Booth, Warlaby.
GOSLINGS.—First, J. Braithwaite. Second, Mrs. Booth, Warlaby.
PIGEONS.—*Carriers*.—Prize, G. Sanders, Stokesley. *Pouters*.—Prize, R. Wilson, Thirsk. *Jacobins*.—Prize, J. Fox, Thirsk. *Tumbler*.—Prize, J. Mason. Any other Variety.—Prize, J. Mason.

CROOK POULTRY SHOW.

THE sixth annual Show of poultry was held at Crook on the 16th inst. The birds exhibited were far superior, both as regards numbers and quality, to those shown at any previous meeting of this Society.

The following is a list of the awards:—

GAME (Black-breasted or other Reds).—First, W. Bearpark, Ainderby Steeple. Second, J. Wilson, Whitworth Woodhouse.
GAME (Duckwings or other Greys).—First, H. S. Stobart. Second, J. Graham.
SPANISH.—First, W. Bearpark. Second, J. Graham. *Chickens*.—First, W. Bearpark. Second, Withheld.
DORKINGS.—First, O. A. Young, Driffield. Second, J. Graham. *Chickens*.—First, J. Graham. Second, D. Rutter, East Rainton.
POLANDS.—First, C. Proud, Binchester Lodge. Second, W. Whitfield, Hutton Station.
COCHIN-CHINA.—First and Second, G. H. Procter, Durham.
HAMBUROHS (Golden-pencilled).—First and Second, Miss A. Ridley, Frosterley. *Chickens*.—First, W. Bearpark. Second, Miss A. Ridley.
HAMBUROHS (Silver-pencilled).—First, W. Bearpark. Second, Miss A. Ridley. *Chickens*.—First, W. Bearpark. Second, M. Pickering, Bishopley.
HAMBUROHS (Golden-spangled).—First, W. Bearpark. Second, T. Mitchell, Mount Pleasant. *Chickens*.—First, J. Armory. Second, T. Mitchell.
HAMBUROHS (Silver-spangled).—First, D. Rutter. Second, J. Taylor. *Chickens*.—First, W. Emmerson, Frosterley. Second, J. Taylor.
BANTAMS.—First, J. Wilson. Second, C. Proud, Binchester Lodge.
DUCKS (Aylesbury).—First, M. Harrison, Pocklington. Second, O. A. Young, Driffield.
DUCKS (Rouen).—First, T. Roddam. Second, O. A. Young.
GESE.—First, M. Heslop, Hamsterley. Second, T. V. Johnson.
TURKEYS.—First, Mrs. Sanderson, Bradley Hall. Second, T. Blackett, Low Shipley.

The Judge was F. Greathead, Esq., of Darlington.

WELLINGTON POULTRY SHOW.

DURING a long succession of years, the shows of poultry and Pigeons annually taking place at Wellington and Bridgenorth, were such as to secure the most favourable opinions of both amateurs and the public generally. It is somewhat difficult for us to say why such shows were discontinued; but whatever may have been the cause of their abandonment, the introduction of poultry again at Wellington, on the 15th and 16th of September, proved that a poultry exhibition is there as popular as it was eight or ten years ago. The crowd endeavouring to gain admission was so great that for even 80 or 100 yards from the gate to simply move an arm was almost impossible. The difficulty of obtaining admission once surmounted, everyone seemed pleased with the general arrangements, and, undoubtedly, much to amuse was offered for inspection. On entering the tent the first object that met the eye was a most unexpected one; being a large number of cases of preserved birds and animals, chiefly foreign, but of great beauty, and although this collection included many rare specimens, all were ticketed at prices that would promote a ready sale. They were the property of Mr. Parton, of Tan Bank, Wellington.

The *Dorking* fowls were not equal to some of those shown many years back at Wellington, but the *Hamburgh* classes were good, and some of the *Game* fowls were well worthy of supporting the reputation of Shropshire in the *Game* classes.

Turkeys were good, and the Hon. Sec., Mr. Jones, exhibited some exceedingly fine Goslings. This gentleman had also sent, simply to increase the interest of the Show, a curious piece of mechanism—viz., a clock surmounted by a tree on which when wound up the birds in the branches appeared to sing loudly, fluttering their wings, and moving their bills in a most life-like manner. A Golden Manakin on the ground appeared to be constantly drinking at a waterfall, smacked its mouth as though pleased at its welcome beverage, and then moved its head as though looking at the visitors in a way that caused great admiration. It cost, we were told, twenty guineas.

GAME.—First, R. Ashley, Nantwich. Second, A. B. Dyas, Madeley.
GAME (Black or Brown Red).—First, T. Radcliff, Cheswell Grange. Second, J. Platt, Swanlow. Highly Commended, T. Groucock; A. B. Dyas.
GAME (Any other variety).—First, R. Astbury, Nantwich. Second, W. Dunnig, Newport.
DORKINGS.—First, E. Shaw, Plas Wilmot, Oswestry. Second, J. Edwards, Eytton. Commended, T. Radcliff.
SPANISH (Black).—First, J. Dean, Wharton, Winsford. Second, E. Shaw, Commended, W. B. Eches, Whitchurch.
HAMBUROHS (Gold or Silver-spangled).—First, Duke of Sutherland. Second, T. Bolton, Hanford. Highly Commended, T. W. Jones, Wellington. Commended, H. Yardley, Birmingham; T. W. Jones.
HAMBUROHS (Gold or Silver-pencilled).—First and Second, Duke of Sutherland. Commended, W. Speakman, Doddington Park, Nantwich.
ANY OTHER DISTINCT VARIETY.—First, H. Yardley. Second, E. Shaw. Highly Commended, Mrs. Walker, Keele, near Newcastle; G. E. Meredith, Ighfield; Duke of Sutherland; W. B. Eches.

DUCKS.—First, W. Hornby, Swanlow, Winsford, Cheshire. Second, T. Radcliff. Highly Commended, E. Shaw.
GESE.—First and Second, T. W. Jones. Commended, J. Edwards.
TURKEYS.—First and Second, C. Brown, Withington.
EXTRA STOCK (Duckwing Game Cock).—Highly Commended, W. Dunning, Newport.

Edward Hewitt, Esq., of Eden Cottage, Sparkbrook, Birmingham, was the Judge.

WEST GLOUCESTERSHIRE POULTRY SHOW.

THE Poultry Show of the West Gloucestershire Farmers' Club was held at Horfield, near Bristol, on the 18th inst. The *Game* fowls and *Brahma Pootras* were very good. The *Geese* fine, and the *Aylesbury Ducks* very large and perfect in bill; Rouen Ducks bad. There were also some perfect *Gochins*, the Partridge variety being the best; and the first-prize pen of *Game Bantams* was very small.

GAME.—First, Mrs. G. Langton, Stapleton. Second, J. Tiley. Highly Commended, C. J. Lambert, Two-Mile Hill; J. Pillinger, Kingswood; R. C. Highnam.

DORKINGS.—First, J. T. Howes, Kingswood Hill. Second, W. Bennett, Yate.

HAMBUROHS (Gold-pencilled).—First, W. Bennett. Second, W. Corbett, Yate.

HAMBUROHS (Silver-pencilled).—First and Second, W. Bennett.

BRABMA-POOTRA.—First, J. Pillinger. Second, J. May, Two-Mile-Hill.

COCHIN-CHINA (Coloured).—First, C. J. Lambert. Second, W. Bennett.

COCHIN-CHINA (White).—Prize, H. H. Howes, Kingswood Hill.

BANTAMS.—First, J. May. Second, J. Pillinger.

GESE.—First, R. C. Highnam, Doynton. Second, R. Hemmer, Westbury.

DUCKS (Aylesbury).—First and Second, W. Bennett.

DUCKS (Rouen).—Prize, Mrs. M. A. Shipp, Yate.

GUINEA FOWLS.—First, J. Batley, Durham. Second, R. Hathway, Frampton, Cotterell.

The Judge was John R. Rodhard, Esq., Aldwick Court, Wington, near Bristol.

WHITBY CANARY SHOW.

THE Show of Canaries held on the 15th inst. was very good. The number of entries exceeded that of last year by 39. The competition being an open one, some superior birds were sent. Last year it was limited to exhibitors within twenty miles of Whitby.

The following is the prize list:—

NORWICH (Yellow).—First, R. Simpson, Whitby. Second, C. Burton, York.

NORWICH (Buff).—First, J. Bexson. Second, J. Baines.

NORWICH (Marked Yellow).—First, R. Hawman. Second, C. Burton.

NORWICH (Marked Buff).—First, R. Hawman. Second, G. Moore.

BELGIAN (Yellow).—First, W. D. Skelton, jun., Leeds. Second, W. Bulmer.

BELGIAN (Buff).—First, J. Bexson. Second, R. Hawman.

COMMON (Yellow).—First, J. Stevens. Second, W. Cotton, Middlesborough.

COMMON (Buff).—First, C. Burton. Second, W. Raw.

CRESTED (Dark).—First, G. Moore. Second, J. Bexson.

CRESTED (Light).—First, R. Simpson. Second, J. Wynn.

CINNAMON (Yellow).—First, J. Wynn. Second, J. Grier.

CINNAMON (Buff).—First, M. Taylor, Whitby. Second, G. Moore.

LIZARD (Golden-spangled).—First, C. Burton. Second, R. Hawman.

LIZARD (Silver-spangled).—First and Second, R. Hawman.

MULE (Marked Yellow).—Prize, J. Bexson.

MULE (Marked Buff).—First, G. Moore. Second, J. Bexson.

ANY OTHER VARIETY.—First, J. Wynn. Second, J. Stevens.

SALE CLASS.—First, W. Raw. Second, W. Inson. A collection of not less than six of this year's breeding, and not more than two of each variety.—First, J. Baines. Second, R. Simpson. Parrot.—Prize, J. Wilkinson. Parakeet.—Prize, G. T. Knaggs.

DISTRICT PRIZES.

ANY BREED (Marked).—First, E. Barker. Second, J. Waters.

ANY BREED (Clear).—First, W. Porritt. Second, J. Hart.

MULE (Any colour).—First, W. Waller. Second, R. Corcor, Whitby.

GOLDFINCH.—First, J. Gray. Second, T. Thornton.

BULLFINCH.—Prize, J. Haw, Gosmont.

LINNET.—First, T. H. Woodward, Whitby. Second, I. Dickinson.

EIGHT YOUNG CANARIES.—Prize, I. Dickinson.

ANTWERPS—JUDGING.

THE most successful winner in the great Pigeon race from Agen to Brussels, though he does not profess selling any of his birds, has been persuaded to dispose of one of the winning birds, with one to match for breeding, to a gentleman at Leith for £20.

The Belgian amateurs select their birds, judging by the development of the skull, eye, length of wings, thickness of beak, colour, &c.; and the most admired of all are those of Liège, the *Smurle* with the Bullfinch shape, notwithstanding the remarks of "AN OLD FANCIER," who by keeping to the old fancy of the inferior Carrier, has been left behind by the tide of progress.

In answer to "AN OLD FANCIER," that any other half-bred Pigeon does for feeding purposes, I say it is as dear to keep half-bred Pigeons as Antwerps, which are in good demand; and

for example I may state that I know some of my fellow fanciers who will be glad to buy good birds of this season at from £1 each; that is some difference from the 9s. per dozen of the half-bred.

And now a word about the exclusion of dealers from shows. I say it is quite impracticable, because every dealer will find a substitute to serve the same object, but let every fancier's voice be heard against dealers undertaking the duties of judges; and it will be for the advantage of both dealers and exhibitors, as one of the greatest dealers said to me, that "Judging is not a pleasant office, as to do my duty I must offend some customers, which is contrary to my interest."

My next communication will be on the comparison and merits of the long and short-beaked Pigeons in general. I will also report the result of the roup pills as I promised.—A FOREIGNER.

THE HONEY HARVEST—LIGURIANISING.

I AM at a loss to account for having such a bad season this year, only taking 60 lbs. off nine hives, whilst last year I took 56 lbs. from a Woodbury bar hive, and 41 lbs. from one and 50 lbs. from another common straw hive. All my neighbours complain, but two of my friends at four miles distance say it is the best season they have had since keeping bees, one having taken 158 lbs. from six hives. Is it that there are too many kept round me? I can count nearly one hundred hives within a radius of three-quarters of a mile.

I have to relate a curious occurrence which I saw last year. I was requested to hive a first swarm that had just left one of my friend's hives, and was surprised to see the bees settle on the neck and shoulders of a boy who was passing down the street. I told him to take his coat off, on which were the bulk of bees, and shaking them off on the ground, I then placed over them a hive, which they still occupy. The boy was not once stung, but was very much frightened. It was a strong swarm, weighing about 4 lbs.

Would it be too late to join a Ligurian queen in October?

Last year I had a very weak stock, the weakest of seven. This year I was surprised by taking more from it than any other. Could the old queen have died in the summer, and a young one been raised?—A TUNBRIDGE WELLS BEE-KEEPER.

[The honey harvest has been very capricious, varying much in different localities, and in some only short distances apart. Overstocking can scarcely be the cause of your comparative failure, seeing that you did so well last year.

October is certainly not too late for putting Ligurian queens at the head of stocks of common bees. In fact, there is less than the usual amount of risk at this season.

It is by no means impossible that your whilom weak stock may have raised a young queen, although such a change of dynasty would be more likely temporarily to retard than immediately to advance the prosperity of the colony.]

BEEES DECAPING.

Two strong healthy swarms of bees in Stewarton boxes that had made abundance of fine honey in supers, which were taken, each weighing 24 lbs. and 25 lbs., and were left with an ample supply to last them till next honey season, disappeared suddenly, leaving the combs quite empty.—GADGIRTH.

[We should be disposed to ascribe this remarkable desertion to one of two causes—either you were deceived in the supposed amplitude of the supply of honey, and when provisions ran short the bees quitted their hives as "hunger swarms," or the desertion was not quite so sudden as you imagine, in which case it may possibly have arisen from the loss of queens. We have known instances of this kind in which stocks have been plundered of every particle of honey before their proprietors have become aware of their loss, the systematic operations of active bands of freebooters having been in the meantime mistaken for vigorous working on the part of the lawful but really dispossessed inhabitants.]

EXHIBITION OF BEES.

Nor having seen in "our Journal" any account at any time of bees having been exhibited at poultry shows, I send the list of the winners in that class. I think if prizes were given at most of our shows for best collection of bees in improved hives, also for best bell-glasses of honey collected in the year, it would encourage bee-keeping, and be a source of pleasure

and profit to the working man. All shows held after the 1st of September would suit bee-keepers to exhibit both bees and honey.

I may say that I have acted as Judge at the Middleton Show for two years for bees. There were nine entries. The following are the names of the winners:—Best collection of bees, First prize (£2), J. Hall, Tonge, Lancashire. Second (£1), C. Turner, Foxdenton, Lancashire.

Last year there were prizes for the best bell-glass of honey, &c.—SOUTH LANCASHIRE BEE-KEEPER.

OUR LETTER BOX.

MOULTING (J. A. Bantam).—Relative to promoting moulting, the following is stated in our "Poultry-Keeper's Manual":—"All birds require more warmth and more generous diet during this time of drain upon their system. This is especially the case with old fowls. Do not let them out early in the morning if the weather is chilly, but feed them under cover, and give them warm soft food chiefly, such as bread and ale, milk porridge made very thick with oatmeal, a little boiled meat, such as liver, &c., cut small, potatoes mashed up with pot liquor, and a little ground pepper mixed daily in their mess."

HATCHING BANTAMS (Philornis).—If you wish to breed very small Bantams, hatch them late, in the end of June or in July. If you want strong birds reared with little trouble, hatch them in April or May.

FOWLS' EVENING MEAL—INFLUENCE OF HATCHING HEN (*Idem*).—If fowls will not leave their perch for food, they do not want it; never attempt to coax or force them. Your informant is either very credulous himself, or he thought you were. It is utterly impossible the breed of the sitting hen should have any effect whatever on the produce of the eggs she hatches.

FOWLS EATING SHEEP'S DUNG (E. A. S.).—All birds like to scratch and pick in the way you mention, and on the same material. It is harmless, but pleasant neither to see nor think of.

SPANISH COCK BLIND (Subscriber).—Spanish cocks and hens are subject to the swelled face you mention, and it always ends in the loss of the eye; but we have seldom, if ever, known it attack both sides of a face. It is incurable.

GREY AND TUFTED BANTAMS (A Novice).—The Bantams, grey and tufted, are not Game Bantams, and must be shown in Class 3, "Any variety except Game." There used to be a breed of Lark-crested Game, but they had no tuft between the eye and ear-lobe. Such were called Muffets. They were once admired, but are now seldom seen. All Bantams are now so much noticed, that we should expect these you have to be very attractive.

THE POULTRY CLUB (Egomet).—We believe the Poultry Club ranks among the things that have been. We know not the source whence come the cups at the Birmingham Show, unless they were the legacy of the defunct, or of some members who wish to enshrine the memory of the deceased. As two poultry clubs have died a natural death, we do not think it likely there will be a third.

BREWERS' GRAINS FOR CHICKENS (X. X. X.).—We have tried brewers' grains as food for poultry. We found it too stimulating, except for laying hens. We believe the grains are injurious to all poultry, and have a tendency to produce dropsy. We sometimes give grains mixed with meal, one part of grains to two of meal, but only in hard weather.

PIGEONS (J. T. C.).—We do not know where Mr. Eaton's work can be obtained. It is one of the crudest of books.

HARTLEPOOL POULTRY SHOW.—"In reply to Mr. Hawkins respecting the decision of the Judges in 'Any variety not named above,' the first prize was given to Brahma Pootras, not Houdans. There were only two pens of Houdans exhibited, both mine, one with crests, whiskers, and beards, the other only with crests. The second prize was given to the inferior birds only with crests. The better birds bred from a cock and hen which won the first prize last year at Preston, and which I sold for £3, were awarded no prize. My Rouen Ducks were second to Mr. Leach's when Mr. Dixon, of Bradford, was Judge. Of those which were awarded the second prize at Hartlepool, the Ducks had white feathers in their necks, and it is well known that Rouen Ducks ought to be similar to the wild ones.—J. G. MILNER, Bellerby Vicarage, near Leyburn."

ERRATUM.—In the fifth line of the second paragraph of the article in page 214 on the Manchester Poultry Show prize list, for "do little," read "do battle."

"BEE-KEEPING FOR THE MANY" (S. B.).—A new edition (the seventh), is just published, and may be obtained of any bookseller, or direct from this office for five stamps.

HIVES AND BEE APPLIANCES (Mrs. Francis).—Of Messrs. Neighbour, 149, Regent Street, and 127, High Holborn; also of Mr. Marriott, Tropical Department, Crystal Palace.

TOMATO JAM.—"In answer to 'T. W. W.' who wishes to know my receipt for making tomato jam, it is as follows:—To every 3 lbs. of fresh-gathered ripe tomatoes, add the juice and fine cut rind of two lemons. Boil together half an hour, then add 4 lbs. of loaf sugar, and a little crushed ginger, and boil the whole during another half-hour.—LOVEAPPLE." The request of a correspondent for a receipt for making tomato jam induces me to give our experience in making this really delicious preserve. The red tomato, to keep well, requires much boiling, and close careful tying-down with bladder. Take note of the weight of the dish, fill it with five ripe tomatoes, and put it in a moderately warm oven for several hours, until they will pull without difficulty. Either before or after this taking, remove the skin. Weigh the tomatoes, add to them half their weight of sugar, and the juice of a lemon for every 4 lbs., boil them in a preserving pan until the juice will set, put the jam out in jars, and fasten them down securely. I believe the small cherry tomatoes are the best of the red kinds; but all these require a good deal of boiling. The small yellow variety requires no more cooking than plum jam, and is very fine in flavour.—E. W."

From observations taken near London during the last forty-one years, the average day temperature of the week is 52°; and its mean temperature 43.2°. The greatest heat was 80°, on the 5th, 1834; and the lowest cold 25°, on the 5th, 1865. The greatest fall of rain was 1.06 inch.

EARTH HEAT.

(Continued from page 41.)

COLD PITS.—These structures being well known, and extensively employed for the preservation and growth of plants, any remarks upon them must necessarily possess little novelty; but considering that few improvements on pits of this description have been made, and that they remain almost in their original condition, I will point out what

I consider would tend to diminish their great, and, I believe, only drawback—damp. I do not think cold pits are the ideal of perfection; indeed, I am persuaded that for affording protection to plants from the cold and wet of winter, and the fluctuating heat and drought of summer, they are but in their infancy. It seems strange that we should employ for the summer decoration of the flower garden plants that are in winter the better of roasting in what is very often little less than a glass oven. We are told that if fire heat be not given in frosty periods, and to dispel damp, the plants will all perish. I do not consider frost need be so much dreaded as it is, nor that it is necessary to maintain such high temperatures as are often given to keep it out; and as to damp, surely that is not dissipated by putting on a fire when very commonly the structure is kept closely shut up as if there were a danger of frost or damp air entering. Now, for plants which need no further protection in winter than from frost, I look upon the erection of a place with glass at the top, ends, and sides as simply striving to build so that as much artificial heat as possible will be required. Is it possible to obtain warmth by employing a material so favourable as glass to the cooling of heated air? Its use to twice the extent that is necessary in the construction of houses in which plants are required to be wintered safely, and with as small an expenditure of fuel as practicable, is simply waste, involving an additional first cost and a maximum of annual expenditure. It is vain to seek for a heating apparatus that will afford the maximum amount of heat from a minimum of fuel, so long as we go on building our greenhouses and hothouses with double the extent of glass roof and sides that is requisite, employing glass in place of some frost-resisting material.

We must, however, not only seek to secure the preservation of plants from frost, but other conditions essential to their existence. These are, besides a suitable temperature, light, air, and a sufficiency of moisture. The first of these, temperature, we have stored up for us in the earth; all that we have to do is to prevent its escape or ward-off cold. This may be effected by affording sufficient covering, but as there must at times be waste, any loss of stored-up heat should be made up for by catching more heat in mild periods when the external is warmer than the internal atmosphere, and enclosing it before it becomes cooled. As regards light, erecting houses with side lights for wintering plants not required to grow, but to be kept safe and in health, is a mistake. If plants are excited by heat, and growth takes place, by all means afford light; but if they are stimulated

by artificial heat when Nature would have her subjects at rest, the case is not then one of the preservation of plants, but of forcing, and to that I intend none of my remarks to apply, for I shall not introduce any heat beyond that of the sun, and what it leaves stored-up in the earth. There is, therefore, no fear of the plants being unduly stimulated; no growth will take place but when the external temperature is equal to or above that of the pit or house, and at such times the exposure of the pit will have a tendency to give increased heat, instead of reducing the internal temperature, and the plants thus derive the light required for healthful growth. What good a powerful light can do plants that are inactive I cannot comprehend. Side lights, and in a measure end lights, I look upon as worse than useless. All the light we require is that admitted by covering with glass in the most economical manner the area occupied by the plants. "What, dispense with side and end lights! The plants will draw." Not at all, if only artificial heat be afforded, and the plants be allowed to rest. Look to your fathers in these matters, the Dutch. "And return from the very elegant and aristocratic span-roofed house to the Dutch pit?" Just so, and why? Because these structures cost less, are less expensive to keep up, and answer their purpose quite as well. "But this is a retrograde step." Perhaps it may be, but I think it a very necessary one, for of late very many have so extended their taste for the massing of tender plants that, finding it such a drain on their resources, they are glad to back out, and advance Beetroot, Scotch Kale, and the like as substitutes: which, at the risk of being thought singular, I consider as much out of place in a flower garden as vegetable quarters devoted to flowers are in a kitchen garden.

Air, it may be said, cannot be given plants in pits when the external atmosphere is frosty, and without it there will be an excess of damp. This may be the case when artificial heat is employed; but in an unheated structure there is little to dread on that head, as the evaporation is extremely small, and what excess of moisture there is may be carried off by judicious ventilation.

As to damp, that certainly is a serious evil in pits; but why should it not be overcome? Great as the evil is, I look upon it as an evil arising from the bad selection of a site and from bad construction, rather than as an obstacle to the preservation of the plants. In the selection of a site prefer high to low ground, but if there is undulating ground, take the southern side of a ridge; or a sloping bank will be an excellent place, particularly if it face south. The more sheltered the situation the better, and if the soil is sandy or gravelly, if water does not remain stagnant within 3 feet of the surface, and there is a good fall for any drain that may be necessary, so far as site is concerned such an one is eligible, but as there are not sites offering all these advantages in every garden, take the driest, most sheltered, and most easily drained. If the ground slopes, it will be necessary to remove the soil at the back, so as to form a pit that will be of the required depth, which for plants planted out or put in as cuttings in the bed need not exceed 15 inches in front and the same at back, but for

plants in pots the pit may vary in depth according to the size of the plants, and in the generality of cases need not exceed 2 feet 6 inches in front, and 4 feet at back. For *Calceolarias*, *Verbenas*, *Gazania*, *Lobelia*, and similar plants, the first-named depth is quite sufficient, but as we may require drainage, and shall need soil, we will excavate 2 feet, making the excavation wider than the required breadth by 2 feet 6 inches. The section of the excavation will appear as shown in *fig. 1*,

Fig. 1.

the soil being taken out 2 feet deep in front, and only 6 inches at back. This will give a good slope to the front, and will answer quite as well as going down the same depth at back as in front; and in digging it out let the soil be thrown clear of the excavation, to the north of the pit.

The walls are to be built hollow, and may be 4½ inches in thickness, with a 4½-inch cavity between them. Commence by laying a course of bricks all round, and headers, so that there may be an 18-inch base for each double wall. The inner walls are to have the first course of the 4½-work laid pigeon-hole fashion, and in or on asphalt instead of mortar, and the course of bricks above it also set in asphalt, but the remainder of the work should be done in mortar. Within a course of bricks from the top half a brick should be left out at every 3 feet, commencing at 18 inches from the end; and a 3-inch earthenware pipe ought to be introduced through the openings left in the outer walls, and having a bend it will fit exactly, and come somewhat above the ground level. The course above the openings must have a heading course of bricks, and this so as to close the cavity, and for the front I would recommend it to be laid in Portland cement, but at least make the joints good by pointing with cement. The back course I would supplement, after the frame is put on, with a course of bull-nose firebrick on edge, and make the joints good with Portland cement.

The frame, of red deal, may be 4½ by 3 inches, and that of the lights 2½ by 2 inches, the sash-bars 2 inches by 1½ inch, and in place of chamfering the edges on the under side, or beading or moulding, rebate them for glass the same as the upper side, and you will have means for double glazing. Paint with three coats of white lead and oil, and put in the inner or under side of the lights 15-oz. glass without a lap, and use no putty, but secure with a light wood moulding. Glaze the outside with 21-oz. sheet glass in the ordinary way. The whole of the wood-work should be well puttied and painted, and made drip-proof, and a 3-inch semicircular iron spout should be fixed in front to the frame to carry the water from the lights.

Fig. 2.

We have in the pit, *fig. 2*, a winter mean temperature of 38°, or we have that temperature in the earth, and may have it in the pit providing sufficient covering be given to retain it. Though sunk in the ground the pit will be fairly dry, for the walls, *a, a*, will keep damp from the inner walls, *b, b*, and damp cannot rise up them on account of the lower courses being laid in asphalt. Any water accumulating in the area or cavity, *c, c*, will descend to the bottom, and pass, as regards the back, into the drainage through the pigeon-holes, whilst the front will take the water from the drainage, and that in the front cavity should communicate with a drain. Any damp rising in the cavities is to be dissipated by removing the wood plugs that close the pipes, *d, d*, which will cause a change of air in the pit at any time, and that may be effected without opening the lights in dull, damp weather, when the heat of the pit is deficient.

Much may be done in the way of securing more heat by keeping the lights closed in sunny days, and ventilating through the pipes, *d, d*; and another use of the pipe ventilators is, when the external air is warmer than 38°, they may be opened for a few hours in the middle of the day, and a change of air thus given the plants, as well as the temperature increased, and this without removing the covering. The pipes all have wood plugs, kept close when the atmosphere is below 38°, and open when above that temperature, day and night.

The lights being double-glazed a more uniform temperature is secured, and the temperature is not so quickly lowered, such lights being equal in protection to a single covering of mats. No water can enter the cavities from above; it is cut off by the cemented course of bricks, and the water does not run from the lights and enter the ground by the front wall, and make that wall wet, but is taken off by the spout. The soil is placed all round the pit, level with the under side of the wood frame, or level with the course of bricks set in cement. We have, therefore, the full benefit of the heat of the earth. Without protection 10° of frost will be kept out when not of longer continuance than an evening, or a night, and with a 9-inch covering of dry straw, or litter of any kind, which must extend over the pit as far as the pipes, *d, d*, the pit is proof against any frost occurring in our climate; but a 6-inch covering will in most cases be sufficient. The covering put on should remain day and night so long as the ground continues frozen; but in case of fine days, when the frosts at night are thawed before midday, the covering should be daily removed, and replaced on the approach of frost. The pit should not have less than 6 inches of drainage, two-thirds of coarse material, and then one-third of finer, finishing with 6 inches of soil.

To winter plants safely, it is necessary that the soil be kept dry. The plants, therefore, should be rooted in good time, the cuttings of all kinds being put in in August, except those of *Calceolarias*, which are best put in during October, just before frost; and the plants should be well hardened off, and the soil dry by October. The reason of many plants being lost in wintering, is that they are struck late, are succulent in growth, and very susceptible to cold. So long as the foliage of the plants does not flag, the soil cannot be too dry.—G. ABBEY.

MARÉCHAL NIEL ROSE.

THE Bath Horticultural Society is one which Nature most assuredly seems to smile upon, for it possesses a charm in having almost, as a matter of course, a fine day, and a splendid one it was on the 9th of September, and a wonderfully good show, taking into consideration the intensely hot summer we have experienced.

Tent No. 1, filled with a rich display of fine-foliaged plants, Ferns, Cacti, and cut flowers in great abundance, is that to which I wish to draw the attention of the readers of THE JOURNAL OF HORTICULTURE, and let them imagine one hundred and fourteen fine blooms of *Maréchal Niel* Rose being exhibited by Mr. Samuel Pavitt, Rose Cottage Nursery, all in different stages of development. A glorious sight they were, clearly proving that this choice variety can be successfully cultivated in the west of England. Mr. Keynes, of Salisbury, had also some remarkably high-coloured blooms.

Mr. Pavitt's were cut from a number of robust and healthy plants growing in his garden. This Rose is there budded on the Briar, which seems to suit it in every particular, as numbers of blooms in all stages are now (September 15th) to be seen in the garden. There is no mistake about its being a free bloomer, and I know no reason why it may not prove quite hardy when thoroughly established.

What a fine sight it would be at any future exhibition, if some spirited nurserymen and amateurs were to agree to grow a number of plants of select varieties, and exhibit boxes of such Roses as *Maréchal Niel*, *Cloth of Gold*, *Gloire de Dijon*, *Souvenir de la Malmaison*, with Hybrid *Peperuals* *Alfred Colomb*, *Charles Lefebvre*, *John Hopper*, and *Comtesse Cécile de Chabrillant*. If these were shown together in a tent devoted expressly to them, what could be more beautiful? and does not he who has written this article wish he may live to see such a sight!—AN ARDENT LOVER OF ROSES, Bath.

POTATOES AND HOPS.—We have been obliged by the following official returns from the Statistical Department of the Board of Trade. The average of land in Great Britain under

Potatoes in 1868, was 539,954 acres, against 492,217, in 1867, and 498,813, in 1866. The average under Hops, in 1868, was 64,488 acres, against 64,281, in 1867, and 56,578, in 1866.

NOTES ON PEACH AND NECTARINE GROWING.

(Concluded from page 221.)

PROTECTION.—The main object of protection is to keep the blossoms dry. On the tops of hills, where hoar frost does not prevail as it does in valleys, less protection is needed. Thatched mud walls do not require so much protection as brick walls with narrow copings. Fir boughs may suffice for such situations and circumstances, but in valleys they will only harbour the damp without keeping it out of the blossoms. If the blossoms are wetted and a frost succeeds, they will wither away as soon as the sun is powerful. I have often been amused at seeing these trees protected (?) by rabbit nets. As well might a shepherd on Salisbury Plain put a hurdle against his back to keep out a driving rain! To make up for the loss of night dews I water my trees, which are protected by sheets. These sheets I put on soon after Christmas to prevent the whole tree being injured. People suffer rain and snow to fall on their trees, a thaw melts the snow, which subsides to the knots, a frost comes on before the tree is dry, and canker at the knots ensues. Canker is more from without than from within. The skin is killed at the knots, where the passage of sap is always difficult, and hence canker and gum are produced. Strong roots are not the cause of canker, but merely ancillary. I am inclined to think that glass copings resting on brackets, and removeable at pleasure, would be a good plan. In cold, wet sunless summers they would greatly help to ripen the fruit, also the wood. The success in the future year depends mainly on the management and ripening of the wood of the current year. Peach and Nectarine trees should be mulched, at any rate during the first winter and summer after planting.

THE FORMS OF TREES.—I think the fan form is best. I, however, use cordons, also trees on high stems to go between the trained trees, which should not be suffered to grow higher than 7 feet, with 14 feet expanse. By allowing trees to ramble high and wide, especially with long-pruning, their centres and bases become bare, and their main stems like rake-handles. It is a good plan to fill up spaces between the trees with single, double, or triple cordons placed perpendicularly. If cordons are placed at an angle of 45°, you must plant so as not to be obliged to strain them with tight ligatures, which will stop the circulation of the sap and produce gum in proportion to the sap. I plant mine upright.

REMOVAL OF LEAVES.—After the crop is gathered, the sooner leaves can be removed without violence the better, to let in the sun and air to harden the bark and buds. In a cold sunless autumn this is a material point. Last year I cut all my leaves in half, without any injury that I can perceive. This year I have done the same. I see it is recommended by Mr. Earley. I am glad to have his confirmation, for I did not know whether it was right or wrong practice. It should not be done while there is a flow of sap. I cut my leaves in half on the 7th and 8th of September. Before this was done the leaves were so green and thick, that some of the wood looked tender.

TRAINING THE ROOTS.—After cropping is over, keeping the roots dry greatly helps the tree to harden its wood, also to ripen it and prevent late, useless, secondary growths. To effect this I shall lay four or five loose tiles, overlapping each other, over the roots near the stems. Unless the winter is very severe they would be sufficient protection to the roots without any further mulching.

INSECTS.—So far as my experience goes, I have never found any trouble except from scale and red spider. Till I came here I never saw the former. Both have been very troublesome this season, so favourable to these pests. They have, however, done no material mischief to my trees. The best remedies are hand-killing the scale and syringing, and constantly syringing the trees affected by red spider. At one time there were a few Peach aphides, of a duller colour than the Rose aphid. These were destroyed by hand-killing and syringing. In syringing, people should jet the water sideways; first one way, and then the other. It is of no use to stand opposite the tree, as red spider and aphides are concealed under the leaves. All curled leaves should be taken off, as the insects conceal themselves and propagate under the edges of the leaves, where water cannot touch them. As the fruit is nearly all picked, I have cut off

half of every leaf, in order to better reach any remaining enemies. I have also poured from a watering pot blue vitriol and water over the leaves so cut. I am persuaded that the spring and autumn, no less than the summer, are the times to keep insects down. They propagate with wonderful rapidity, and the neglect of syringing only for a few days will be followed by a dense population. In order to detect them, people should have a magnifying glass. When the leaves look yellowish on the upper side, and silvery on the under side, the mischief is done. The leaves will not recover their colour. I admire Mrs. Pollock and Lady Cullum Pelargoniums, but I cannot admire bicolor or tricolor Peach and Nectarine leaves.

FUNGUS.—I never remember seeing out of doors any on my Peach and Nectarine trees. I believe mildew is the more common disease, and confined to glass culture. Glandless leaves are said to be more affected by mildew than those which have glands. The reason, I believe, is that viscid secretions, where there are no glands to carry them off, pass through the leaves, that the spores adhere, and in due time, when the weather is favourable, root into the tissues of the tender leaves. Where there are glands, these secretions pass off by the glands. Probably sorts with glands have leaves with closer tissues. I have always observed that Rose plants which have close-textured glazed leaves, are not so much affected by mildew as others. I never remember seeing any on Soliflorae Rose. I mean to dress my trees again after Christmas with blue vitriol and water. Two ounces of blue vitriol (sulphate of copper), to three gallons of water, could do no harm, and might destroy much that would prove injurious. Soft-soap, which contains arsenic, dissolved and added to water, is, I should think, a good winter dressing. With regard to the blue vitriol and water, observe it is only an experiment, and not a recommendation. At any rate, whether our foes are insects or fungi, the sooner we are free of them the better. We may be assured that whatever does harm to the foliage during the time of growth will injure the health of the tree, decrease its longevity, and spoil to some extent the flavour of the fruit. The value of leaves, as respects flavour, is seen in the difference between a Peach or Nectarine that has a terminal leaf, and one that has none. More care must be taken of the foliage.—W. F. RADCLIFFE, *Okeford Fitzpaine*.

POTATOES SUPERTUBERATING.

YOUR correspondent, "A WILTSHIRE FARMER," requires advice, as the earliest-formed tubers have numerous young tubers issued from them. I reply, Allow the crop to remain undisturbed, as there may be just a chance of the young immature tubers becoming ripe before the frost comes. On them "A WILTSHIRE FARMER" must now rely for a table supply, as the first tubers, from which the young tubers issue, will on cooking be found centred with fibre as tough as boiled straw, and worse than a boiled Dahlia tuber. At taking-up time these old tubers whence the young ones sprang should be separated, and boiled down at once for lean store pigs, making the mess palatable by adding salt, with bran or pollard.

I presume fresh haulm is not growing from the young tubers, as it frequently does this season, for in that case the sooner the whole crop is out of the ground the better, and the supertubers merely kept for seed, as I explained in page 146 of this Journal.

I promised to say something about my class Regents, and I now take the opportunity. I took them up last week from three different soils—namely, a light loam, stone-brash, and a gravel-brash, well dunged.

Almond's North Riding Beauty, Regent (second early)—I watched them narrowly, and dug them up the moment they began to "spear," or they would have thrown up a thicket of young tops without forming supertubers.

Gryffe Castle Seedling, the best of all the Regents (I shall grow no other of them for the future), is a capital crop. I believe it would have remained in the ground till next spring without "spurting."

York Regents were a thicket of sprouting greenery, with no crop at all, and of Sutton's Finest Regent, there was a miserable supertuberated crop.

Walker's Second Early Regents supertuberated very badly, and had feathers to their bonnets.

Prolific Regents were small Potatoes, and a few in a bill.

Scotch Rough Whites supertuberated. A miserable crop, rough enough in all conscience, having cracked skins to an unlimited extent.

So much for Regents. The class served me the same in

1859, and 1863, and so they will again to anyone who may choose to pin his faith to them, excepting, I think I may affirm, the *Cryse Castle* Seedling. I have yet three more sorts I grow in the above soils—viz., *The old Flake*, a spare, very ugly crop, speared with greenery; *Salmon Kidney*, with some tubers perfect, and others with "small fry;" *Paterson's Victoria*, good crop. I watched them narrowly, and dug them when they were offering to "spear," otherwise they would have thrown up a forest of green tops without forming any spertubers. These features were the same in all the differing soils, and as regards the last sort in the garden included.

I was lately inspecting several acres of *Flukes* and *York Regents*, at *Redenham*, near *Andover*. The tops were as green as in spring, and in full blossom. As to the crop, three out of four of the *Regents* might be said to have produced two or three tubers, the remainder having some of them strong fibrous roots, and others stout tap-roots striking directly down into the subsoil like young *Oak* trees, having no *Potatoes* attached. The *Flukes* were slightly better, but a remarkably ugly sample, throwing up green independent tops. It was painful to witness the extent of ground that had to be forked over to gain a basket of tubers, and when cooked I likened them to chopped-up, earthy-flavoured candles, wicks and all. In my garden I left the *Lapstone Kidney* to take its own way, and what few tubers it did produce formed spertubers, which threw up independent haulm, and then caught the disease, which killed them all. My beautiful crop of *Taylor's Yorkshire Hero*, and many others of my garden sorts, would have followed suit in this last respect, if I had not copied the "early bird."—*UPWARDS AND ONWARDS*.

THE IMPROVERS OF THE HOLLYHOCK.

As my name has been mentioned by Mr. Abbey, as one of the improvers of the *Hollyhock*, I may, perhaps, be allowed to recall the part I have taken in this work. I have always understood that the late Mr. Baron* was the first great improver of this flower, and that to his efforts more than to those of any other are we indebted for the beautiful varieties we now possess. He broke the ice, cleared away the fragments, and left a smooth and open sea for his successors to sail in. Mr. Chater, Mr. Parsons, and Mr. Roake followed him, and each of them accomplished great things.

To speak of my labours, I must go back twenty-two years. At that time my father, the late Mr. A. Paul, had a large good collection of which he was very proud. I thought them unequalled, until the day I happened to call on Mr. Parsons, then living at *Ponder's End*, and found several kinds superior to ours, and of them he obligingly offered me seeds and cuttings in exchange. I understood him that these varieties were principally Mr. Baron's, but that some of them were his own seedlings. I went to work crossing and raising seedlings, and in 1833 had, I believe, the finest collection in Europe. In that year I obtained thirteen first prizes for *Hollyhocks*, in *England* and *Scotland*, principally with my own seedlings. I think the following, which were raised by me, those who remember that period will say were the best of their colours then known:—*Beauty of Chesham*, *Dizzy*, *White Globe*, *Fireball*, *Superb*, *Argo*, *Darius*, *Romulus*, and *Shylock*. Later I was fortunate in obtaining *Avalanche*, *Primrose Perfection*, *Queen of the Whites*, *Village Maid*, *Blushing Bride*, *Lord Jocelyn*, *Celestial*, *El Dorado*, *Lady Franklin*, *Lady Palmerston*, *Ossian*, *Plutarch*, *Queen of the Yellows*, *Sir Colin Campbell*, *In Memoriam*, *General Havelock*, and many others, all gems of the period, one of the latest being *Beauty of Waltham*. More alluring paths in horticulture (commercially considered, as *Roses*, *Fruits*, *Pelargoniums*, &c.), have kept me from following out the department of raising seedling *Hollyhocks* to the extent then practised: but after the above instances of success, which I have no doubt many living growers can attest, I think it is rather hard of your correspondent, "A HOLLYHOCK AMATEUR," to leave me out in the cold.—*WILLIAM PAUL, Paul's Nurseries, Waltham Cross, N.*

GESNERA EXONIENSIS.—Messrs. *Lucombe, Pince & Co.*, of the *Exeter Nurseries*, have sent us a coloured drawing by Mr. Andrews, of their superb new plant, *Gesnera exoniensis*. Its numerous scarlet flowers are very rich, and standing very erect they are remarkably striking, and the more so on account of

the dark green foliage. It is certainly one of the richest of the *Gesneras*, and a valuable addition to our winter-flowering plants.

MESSRS. RIVERS' NURSERIES, SAWBRIDGEWORTH.

(Concluded from page 170.)

GRAPES have long been a pet subject with Mr. Rivers, and numerous are the varieties which have been introduced by him to our notice, chiefly cuttings from the almost endless mass of continental varieties of the *Chasselas* class, of which the *Royal Muscadine* is a good type. Mr. Rivers has a very large and fine collection; these are excellently suited for orchard-house cultivation, they ripen well and freely without any artificial warmth further than is obtained by solar influence, and the protection from cold blasts. It is really astonishing to see what can be done with *Grapes* without the slightest assistance from fire heat; with the ground vineries, of which we have all heard so much, and with few exceptions believed so little in their favour, Mr. Rivers works wonders. This simple contrivance has been so often noticed and described in these pages, that it will be unnecessary for me to do so. Mr. Rivers was about the first to adopt this simple structure; years ago its success had been proved at *Sawbridgeworth*, and this year the results were even more remarkable. One of the original Vines, a *Trentham Black*, planted from five to six years ago, is now 50 feet in length, is in the most perfect health, and is bearing about 120 bunches of fruit, good heavy bunches; and this, be it remembered, is a variety which is known to be somewhat difficult of cultivation. The berries were of fair size, and colouring well—indeed, much better than one would expect in our best heated vineries, looking at the enormous crop upon the Vine. One-third would have been ample. Mr. Rivers, however, labours not in this instance for the production of a few highly-finished bunches of *Grapes*, such as would gladden the heart of a *Meredith*, but rather to demonstrate the practicability of the system. That it is successful is abundantly manifest. The next Vine, a *Black Hamburgh*, has twenty bunches, the weight averaging nearly a pound each, and they were ripening and colouring off in splendid style, superior to many that I have seen in fine and expensive houses this season. Who need be—who would be, in fact, without his dish of *Grapes*, when it is seen how easily and cheaply they can be obtained? The labourer and the mechanic can by the outlay of a few shillings for the glass, with their rod of ground, produce as good a dish of *Grapes* as a peer.

In one small house about 20 feet long, Mr. Rivers has the Vines planted out vineyard fashion—the same way, in fact, as we have our *Raspberries*—*in*, in lines about 3 feet apart, and trained to stakes about 4 feet in height. In Mr. Rivers's house there are four lines, two on each side of the centre path. This house is not heated, and many of the varieties tried have not succeeded well. Some of them, however, are growing splendidly, and bearing good crops, such as *Foster's White Seedling*, *Ingram's Hardy Prolific Muscat*, &c. The idea of growing Vines in houses in this way, is a very happy one; I like it exceedingly. The plants look extremely handsome, and there is something very pleasing in being thus able to walk round, in, and amongst a grove of Vines, and to be able to inspect every berry and every leaf at ease, instead of being in danger of breaking one's neck by climbing up a pair of rickety steps, as in the ordinary way. It is questionable whether even a greater amount of space is not obtained for the Vines in this manner, than by any method of training over the roof. At all events, for the sake of variety alone, in which there is much enjoyment, it is worthy of adoption. In one of the span-roofed orchard houses, in which the principal rafters are some 10 or 12 feet apart, some *Black Hamburgh Vines* are trained over them very neatly, which when the *Grapes* are ripening gives the house quite a jaunty and elegant appearance.

Oranges are cultivated here very largely in pots. This season's stock of plants exceeds three thousand, in number. They are all of them in most splendid health, and many of them are loaded with fruit. They are principally of the dessert or sweet kinds, such as the little *Otaheite* and *Mandarin*. I have tasted some of the Oranges grown by Mr. Rivers, and they were really splendid, quite as rich as any of our imported fruits, and much more pleasing. It seems strange that there is so very little attention paid to the cultivation of the Orange for the fruit in this country, seeing how very simple it

* See my "Hour with the Hollyhock," Second edition, pages 7 and 8.

is. What a fine addition to our dessert at Christmas would a dish of fresh-gathered ripe Oranges be, dressed up with their own leaves and Orange blossom. I long to see the day when home-cultivated Oranges will be as common at the dessert table as Peaches are now.

Mr. Rivers has such a number of structures and contrivances for the cultivation of fruits, and carrying on his experiments amongst them, that it is impossible to notice all, although there may be some little peculiarity pertaining to each that makes it interesting. There is one large structure 400 feet long, the roof of which only is of glass, the back composed of boarding, and the front open, excepting the slight protection of a common net just to break the severity of the cold blasts. This is used for housing Pears and Plums in pots in spring, until the danger of frost is over, when they are placed out of doors; also for Roses, the whole saleable stock of which is taken up on the approach of winter, and placed here. In this way there are no losses from winter frosts. In a house of this size about four thousand trees may be placed. If these are Pear trees, estimating the produce at six fruits a-piece, and there is no danger of not having that quantity, a very neat return is obtained for the outlay. Mr. Rivers's trees which he had turned out from structures of this sort were, both Pear and Plum trees, loaded with fruits. In one group alone I counted some hundreds. Many of the Pears were of large size, and, no doubt, of excellent quality; they had that full, juicy, warm appearance, which tells of lusciousness. Some of the earlier varieties I tasted. Summer Beurré d'Arenberg (noticed at page 171), is a seedling of Mr. Rivers's, and is in all respects excellent. It has that nice, brisk, rich acidity which makes the old Beurré d'Arenberg, when well ripened, such a favourite. This brisk acidity with juiciness, to some tastes—to mine at least—is far more refreshing than so much muskiness and sweetness, especially in summer.

On the Plum trees in pots there were enormous crops; the little trees were literally loaded, all sorts of them—Green Gages, Golden Drops, from the big Magnum Bonum, to the little Mirabelle. This last is a variety very much like a small Bullace, which is much cultivated in France for dessert. It is very sweet and agreeable, and a most enormous cropper. There were many seedlings amongst these Plums, some very promising, and like the Peaches, of somewhat curious origin; one, a large late blue sort, was raised from Reine Claude de Bavay, which is a rather early green sort. This introduces me again to the subject of raising Peaches, in which I must correct a slight error I have made. The Princess of Wales Peach was raised from the Pavie de Pomme, not from the Silver; and one of Mr. Rivers's theories is, that the Madeleine Blanche, the Malta, and Noblesse Peaches, which are all pale in colour, and piquant in flavour, owe their origin to the White Nectarine, one of the oldest of the race, imported from Syria many, many years ago. The flowers of all of these are similar to those of the White Nectarine.

Of cordons, about which we have heard so much lately, Mr. Rivers has many examples to show, some have been in existence for several years. In France, this style of training in all its various forms is greatly practised, and where well carried out, the lines perfect, and the trees loaded with fruits, as I have seen them, they are certainly extremely pretty. When I first visited France some years ago, and saw the cordon Apple trees as edgings along the sides of the walks, covered with beautiful fruit, as they were then. I was much struck with their beauty, and fancied that when I got home again I would do wonders with them. Subsequent experience, however, has convinced me, that, as a general rule, they are unsuited for this climate, and that after all is said, it is too much like playing at fruit-growing; the expense for attention, &c., is too great for them ever to be largely adopted. As pretty objects of ornament, in suitable soils, where plenty of care and attention can be bestowed, then by all means have your cordon trees, but if all this cannot be given, then avoid them. Mr. Rivers has some lines of these long cordon Apple trees doing extremely well; the best are those grafted on the English Paradise stock, which Mr. Rivers considers the same as the French Doyenné. Those on the French Paradise are not doing so well; some are trained to a fixed wire, the same way as the French do, and which is decidedly preferable to that of pegging them down with hooked wires—another mode adopted by Mr. Rivers, my objection to which is, the difficulty of growing the shoot straight, owing to there being nothing to fix it to; we can peg down, but we cannot peg up, and the tree bends just as often the one way as the other.

The oblique and vertical cordon Plum and Pear trees on the walls and trellises under glass and in the open air, were all looking well, the trees being in fine condition, and full of fruit buds. The masterpiece of all, however—without exception the finest piece of training and gardening in the whole establishment, is a line of thirty-two upright cordon May Duke Cherry trees in the open ground. They are grafted on the Mahaleb stock, and range from 8 to 10 feet in height. Never have I seen more beautiful trees than these, perfect in every sense; from the very ground to the very tip, they form just one unbroken column of beauty, the stems being densely clothed with fruiting spurs, none exceeding much more than 3 inches in length. How beautiful they must have been when in flower, and again when the fruit was ripe. When I saw them the crop was just over; by the stalks remaining on one, I could see that the produce had been immense. Day by day for years, these trees must have been attended to with the greatest care for them to have attained their present beauty. How beautiful a garden would be with lines of trees like these! and Mr. Rivers shows that it may be done.

Another feature here, which in some respects resembles these Cherry trees, was the pyramidal Prince's Englebert Plum trees. There are great numbers of this variety growing in the fruit-tree quarters, the trees about 5 feet high, all loaded with beautiful fruit, from the ground upwards. They were extremely handsome. This is a most excellent Plum, the quality good, and the tree is an extraordinary bearer. What an enormous quantity of fruit could be obtained from an acre of ground planted with trees like these. They might be planted in lines like hedges to divide the quarters in the kitchen garden. Mr. Rivers grafts from five to six thousand a-year of it, so much is it in his favour as a profitable market variety.

I must not omit to notice a most remarkable variety of Cherry—the Belle Amélie, which is to be seen here. There are two goodly-sized trees of it just at the back of Mr. Rivers's house, loaded with fruit. This is the latest variety of Cherry in existence, ripening generally in the end of September, and hanging on the trees until October. I have seen them in November. It is a free-bearing variety, of rather small size, when well ripened very pleasant in flavour. Its peculiarity, however, is this, that the birds do not eat it. Why they do not, it would be interesting to find out. It is sweeter than many others that they do eat. It is well known that our feathered friends also do not meddle with the yellow Cherries, which are as sweet as any. That, however, has been accounted for on the supposition that the birds never know when they are ripe. This theory, however, scarcely holds good, as there are many yellow fruits very greedily devoured by them. Here is a question worthy of the notice of our scientific men.

There is here also, in one of the compartments near the orchard houses, a group of about one hundred dwarf bush Apple trees, that are well worthy of notice. They are about 3 feet in height, just resembling little Gooseberry bushes, and planted 3 feet apart each way. Pretty little trees they are, abundantly set with fruit-buds, and some of them well loaded with fruit, on an average from eighteen to twenty-four on each. These trees are from seven to eight years old, and are kept in their present fruitful condition by being every alternate season transplanted, at least each of them as may seem to require to have their vigour suppressed. It is only by this continual removal, and checking their superabundant growth, that these trees can be kept in such a dwarf and fruitful state. The soil in Mr. Rivers's grounds, however, is one much well suited for this system of culture, being of a light calcareous nature, with a sandy or gravelly subsoil.

It cannot fail to be observed, in walking through Mr. Rivers's nursery, how stubby, short-jointed, and fruitful all the trees seem to be, even in their youngest stage. This may partly arise from the stock on which they are worked, or from their repeated removals. I find, however, chiefly owing to the calcareous sandy nature of the soil. In all like soil, I have always observed that fruit trees grow not so bushy, but bear fruit enormously. It would be quite correct to plant fruit trees by the acre, at 4 or 6 feet apart in ground of this nature. I would be decidedly the more preferable. The trees, whether Apple, Pear, Plum, or Cherry, would bear well in a young state, and through growing bushy, it would be many years before they began to crowd. I have seen, at Harold House, however, the case would be far different, such as in the Malaga seedling of the Thorns. These young trees set out like Willows, and bear but little fruit, all the time being produced on the other side of the trees that have been allowed a little more of Nature's way. The

attempt to keep them within the same compass, by pruning, pinching, or transplanting, as those that may be growing on the lighter soils, is always done at the expense of the crop. The trees may be formed, but the fruit will be wanting, and it is for the fruit that they are grown. A rule that may be perfectly suitable for one district, is totally inapplicable to another, and to plant trees, and pursue the same methods of cultivation in different situations, without regard to the constitution of the soil is simply absurd. I would recommend all who are fond of this fancy miniature fruit-tree gardening, before adopting it to visit Mr. Rivers's establishment, and see how it is done there; that they will be delighted I have not the slightest doubt, but it is that they may be benefited that I recommend it. A day at Sawbridgeworth or Bonks Hill (the old name of the place), with Mr. Rivers, is a day well spent.—ARCHAMBAUD.

AUTUMN-FLOWERING WHITE PINK.

I do not know whether this desirable plant is well known. I never saw it until to-day, when taking a stroll through the Dorset Nurseries, at Blandford, now being entirely remodelled under the care of the present proprietor, Mr. H. Blandford. I noticed a bed of it in bloom; it is simply the white Pink, with which we are all so familiar, but evidently grown a double flower. As it was full of flowers and buds ready to open, it might surely be made a valuable plant for bouquets if grown in pots, as it would, doubtless, go on flowering for some time; and for places such as Brighton, where flowers are much needed during the autumn months, I should think it would be very useful.—D., *Deal*.

GOLD AND BRONZE PELARGONIUMS.

I HAVE at various times been surprised at the amount of misconception existing respecting the origin and parentage of the varieties of Gold and Bronze Pelargoniums, it being frequently asserted that Beauty of Oulton is the parent of all this section of popular plants, than which nothing can be more contrary to fact. For several years prior to its appearance, such varieties as Mrs. Milford, Annie Williams, and Mrs. Hutton, were catalogued by Messrs. Henderson, of the Wellington Road Nursery; Luna, by Mr. Saltmarsh; and Sceptre d'Or, by Messrs. Downie, Laird, & Laing. Any one of these has a better claim to be called golden than Beauty of Oulton, which clearly had nothing whatever to do with their production. It is a representative of a section of Bicolors which have more green than yellow, and which, as usually seen, might with propriety be called the Bronze and Green section. They have, it is true, enough yellow to make them under certain circumstances a very pretty class of plants, but unfortunately they are wanting in constancy of character. Model, one of this class, is really very pretty, but too dull and heavy for a bedder where distant effect is studied. Beauty of Calderdale is, perhaps, the best for bedding, though better suited for pot culture. Like Beauty of Oulton it lacks constancy of character when planted out. Glowworm and Circlet are far too green to have any claim to be called Gold and Bronze. Beauty of Ribblesdale, again, is often quite green. A narrow-belted variety which would, when planted out, retain the yellow ground throughout the season, would be a great acquisition.

Advances on the varieties to which I have referred, are those of which Egyptian Queen may be considered a type; these have a bronze-yellow ground with broad heavy zones, and in the hands of a skilful cultivator become very beautiful objects for the exhibition table; but so far as we may judge of them, as seen at Battersen Park, the bronze and green shades render them anything but the effective subjects for bedding purposes which the flower gardener will always require for out-door decoration.

Sceptre d'Or was the first of the bright Gold and Bronze varieties, and where known it has been a great favourite, though, like many others, it must give way to the improved varieties of which it may be considered a type. These have a different habit of growth from those already mentioned, are much brighter in colour, and form a better contrast with *Coleus Verschaffeltii*, than any other yellow-leaved plants, the Golden Pyrethrum not excepted. This is especially the case with Kentish Hero, which will, and without any trouble, keep pace with the *Coleus*. Having also a large leaf, with a distinct zone, which may be seen from a great distance, and a robust habit, it is one of the most desirable plants of the season. It has held its own

against all others at Chiswick, and will, no doubt, become a great favourite, being not only beautiful, as seen when near, but at a great distance it is quite as effective as a good bed of yellow *Calceolarias*. I fear I may have trespassed too far on your space, but this is a section of Pelargoniums of which I am very fond, and which I think will quite eclipse Tricolors as bedding plants, though they may not surpass them as examples of individual beauty; but even this remains to be proved.—W. B. G., *Rutland Road, Perry Hill*.

A FRAGMENT OF DORSETSHIRE.

A FEW weeks only have passed since I was staying at Weymouth, or, to speak more truly, at Melcombe Regis, for all the most worthy of residences are here, although the name of its twin borough of the other side the river Wey prevails so far as now to include the whole. So soon as I had provided the where to rest and the wherewithal to gladden the heart and to give a cheerful countenance—though be it observed that the latter effect was brought about by other agents than oil—I pursued my wonted course, and sought for the local guide books. I am prone to patronise local literature; but (that is a benumbing monosyllable), I am obliged to confess that, bad as such literature usually is, the local literature of Weymouth is in the superlative of defectiveness. I would forgive its meagreness if even it was correct meagreness; but it is just the other thing, and especially upon topics which interest me most. I believe that Iridical blood is in my veins, for I venerate "Gospel Oaks," and have pilgrimed to every tree of celebrity between the Wallace Oak and Burnham Beeches. So when I read in one of the Weymouth guides of "Culliford tree" I rejoiced inwardly, and prepared to unravel legends, and jot down for your pages marvels of interest. Now, I will wager my golden pen against a crowquill stump, that not one of the readers of those pages would guess that no such tree exists. Yet such is the fact, and Culliford tree is the corruptly spelt name of one of the divisions of the county! So I put no faith in the guide books, and accepted that most unerring of informants, the Ordnance map; and with that in pocket I know of no more enjoyable mode of "looking around" than strolling on to a church the tower or spire of which peers up above distant trees, and, having reached it, inquiring the name, and then rummaging one's memory and books to find out "all about it." This was my occupation during a day in August last past; and the church I reached was that of Portisham, a village distant from the old highroad, and further still from the iron way, nestling into the base of the chalk hill rising above it. Such quiet out-of-the-world places seem suited only to the production of men whose "talk is of bullocks," and of women to sit in the sun and knit stockings; so it comes upon us surprisingly when we find that such a place of quietude has produced one of the world's great ones. And Portisham causes this surprise, for here was born that Sir Thomas Hardy who was the brave companion of Nelson and Collingwood. Your pages are not the fitting place in which to dwell upon their naval deeds; but space may be spared to note that they all delighted in gardening. Nelson used to set-to and dig in his garden at Merton as if he was doing piecework. Collingwood's charming letters to his daughters show how his heart yearned to be at home, to make holes with his walking-staff, and drop acorns into them where a fitting vacancy offered itself.

There was but little to detain me at Portisham, so I rested beneath the shade of one of its Elms, and consulted the unerring map. It revealed that the road before me led to Abbotsbury, and of the swannery there I had often read, so I was promptly up and away thitherward.

The previous day I had reached Fleet, the fishermen's village whose church was swept away by the wondrous tide of the 23rd of November, 1824, and the height of which is shown to have been 23 feet above its usual high mark by the record on a pole, to which you have to raise your eyes at the Abbotsbury Decoy. To the interior of that treacherous enclosure I was now admitted; but the swannery at that, the breeding, season, was forbidden ground. It is in the broad part of the Fleet, as the narrow strip of sea there is called, and there are kept six hundred and more swans, though it is certain that more than twice that number were there formerly; and including "hoppers"—that is, a small species, which fed, ranged, and returned, some accounts enlarge the numbers to eight thousand. It is certain that five hundred were there in the reign of Elizabeth, each of the value of 2s. 6d., and possessed by Joan, widow

of Sir John Young, Knt. All the unmarked white swans, four hundred in number, were then seized in pursuance of the Queen's writ, for if found in a river unmarked they belong to the Crown. Joan then pleaded that "there was time out of mind a game, or flight, of wild swans," belonging to the abbots of the monastery of Abbotsbury; that the swans were not marked, but the abbot marked some of the cygnets yearly, by cutting off part of the pinions, and these were for helping to sustain the monastery's hospitality. She further pleaded that Henry VIII. at the time of the monastery's suppression granted the swannery to Giles Strangeways, Esq. Joan's plea prevailed; she was wedded to one of his descendants, and to his descendants, now Earls of Ilchester, the swannery still appertains.

Swans were especially valued by our ancestors, in whose banqueting regard to quantity far surpassed daintiness as to quality. This is testified by the boars' heads, barons of beef, and porpoises which loaded their oaken tables. So the law specially protected the said swan for its cut-and-come-again merit. It was the only bird that could be claimed by its owner as a stray; and he who stole one had to render to its owner as much corn as was necessary to cover another swan hung up by the beak, which, considering its length of neck, must be not a few bushels. One of the standard dishes of the first course for Henry VIII.'s dinner "on a flesh day," was "swanne, great goose, or storko;" and as early as the fifteenth century this was the orthodox sauce or "CHAUDERN FOR SWANNES:—Take the lyver and al the offall and make hit clene, and let hit sethe, and when hit is sothen, take hit up and pyke oute clene the bones, and dresse the lyver and al the entraile, and chop the best; and take bredde steped in brothe, and drawe hit up with the blode and brothe thurgh a streynour; and do hit in a pot, and let hit boyle, and do therto wyn, and a lytel vynegar, and ponder of pepur, and of elowes, and of gynger, and serve hit forth."

Foiled in my purpose I strolled back to Abbotsbury, and in its churchyard near the door through which he passed into the church, is a raised gravestone thus inscribed:—

WILLIAM THOMAS HORNER,
4TH EARL OF ILCHESTER.

BORN 7TH OF MAY, 1795; DIED 10TH JANUARY, 1865,
"The Memory of the Just is Blessed."

At one end of the gravestone is the family heraldic shield and motto, "*Faire sans dire*," (To act without boasting)—by his example especially appropriate, for no one looking at that gravestone, neighboured as it is by the greensward mounds over the village dead, would think that a descendant of the Plantagenets lies there. Yet so he was, for the Strangeways come lineally from one of the sons of Edward III.; and William Thomas Horner Fox-Strangeways, whom that stone commemorates, was one of the most worthy of the race. He had long been employed in the diplomatic service of England; and whilst acting as Secretary of our embassy at Vienna in 1832 he noticed the *Pinus austriaca*, or Austrian Pine, and introduced it into this country. When Under-Secretary of State at our Foreign Office he had the opportunity, and fully availed himself of it, to promote the acquirement of new plants; and the Transactions of the Royal Horticultural Society record the names of many rarities which he contributed to its stores. When he retired from public life he made the culture of plants still more his recreation. The mild climate of Abbotsbury rendered that the favourite repository for his plant treasures, and this, and other associations telling of a loving heart, prompted him to direct that, though he died at Melbury, his last resting-place should be near his mother in Abbotsbury churchyard. The best testimony to the Earl's worth was this by Mr. McNeil, the gardener at Abbotsbury—"He was liberal to his tenants and servants, and a true friend to the poor."

I had often heard of Melbury as the mansion of the Ilchesters, but no one ever talked of their Abbots Castle residence. The keeper of the decoy first aroused my attention by saying, "There is a wonderful many strange trees in the garden." Then I remembered a photograph of an Agave that flowered there—but it is a photograph probably unknown except in the cottage window of Mr. Green, the really clever photographer at Abbotsbury. These facts combined made me resolve to see the Earl's garden, and thoroughly well was I repaid for my determination.

Every great patron of plant collectors has some special mode of enjoying the novelties they introduce. The late Duke of Devonshire, for example, had them one at a time brought before him as he sat in his easy chair, and he had the then Mr. Paxton with it to talk over the plant's peculiarities. The

Earl of Ilchester, on the other hand, had no delight in potted plants, but he was unwearied in accumulating those into his Abbotsbury garden which he thought might endure our climate. The result was before me, and never did I see such an accumulation in a small garden in any other corner of the British Islands. Mr. McNeil, the obliging and well-skilled gardener, really bewildered me as he took me from one shrub and tree to another, planted without the slightest attempt at order, but evidently stuck in as soon as received in any place where there was a vacancy.

For the following list of some of the trees, shrubs, and other plants I am indebted to Mr. McNeil:—

Garrya macrophylla
elliptica, male
elliptica, female
Aralia longifolia, 12 ft. 10 in.
trifoliata, 11 ft.
Shepherdia
Sieboldii
papyrifera
Eriobotrya japonica, 15 ft. 10 in.
Clethra arborea
Kerria japonica
Ceanothus puniceus
Laurus indica
coriacea
fortens
canariensis
lurbonica
regia
carolinensis, and others
Hovenia dulcis
Sterculia palmata
Lagerstroemia indica, 14 ft. 6 in.
In the shrubby in perfect health, but has never flowered. One on a south wall for the last twelve years is now in beautiful bloom for the first time.
Thea assamensis
bohea
viridis
Punica, red and white, flowering well.
Psoralea glandulosa
Pittosporum undulatum
bracteolatum
scoparium
Mayii
tobira, and others
Ilex magellanica
perado
serrata
ferox
crassifolia
fructu-luteo
balearica
dahoon
latifolia
opaca
vomitoria
mexicana, and others
Carmichaelia australis
Quercus agrifolia
japonica
reticulata
annulata, beautiful. And Alcock's, Turner's, Miller's, and a great variety of American and other Oaks, fine.
Edwardsia microphylla
macrophylla
grandiflora
recurva
chrysophylla
Pistacia lentiscus
narbonensis, and others
Nandina domestica, 11 ft.
Prinos glaber
prunifolius

Benthamia fragifera. Of late years fruited well, this season deficient.
Olea exelsa
ibicifolia
Nerium splendens
Phloxia boxifolia
Cantua dependens
Smilax in variety
Escallonia pterocladon
montevicensis
organensis
Eurybia furfuracea
Ceratonia siliqua
Myrtus bullata
Viburnum japonicum
Tetranthera japonica
Primys Winteri, 19 ft. 9 in.
Rhododendron Falconeri
Tasmanian aromatica, 6 ft.
Ceratopetalum apetalum
Mitraria coccinea
Mysimic africana
retusa
bifaria
Rhynchospermum jasminoides
Callicarpa purpurea
lanceolata
Elaeagnus argentea
densata
Eucalyptus montana, 25 ft. 10 in.
coccifera, 7 ft.
cordata, 11 ft.
Magnolia grandiflora, standard, 19 ft. 10 in.
Mandevilla suaveolens
Physianthus albens
Billardiera frutescens
Kadsura japonica
Dentzia gracilis
Dianella cerulea

FERNS.

Cyatium falcatum
Doodia caudata
aspera
Osmunda spectabilis
cinnamomea
gracilis
interrupta
Lomaia magellanica
chilensis
alpina
Polystichum vulgare proliferum
Nephrodium acrostichoides
Adiantum fulvum
Cunninghamii
Phytolacca Billardieri
Pteris erecta
longifolia
serrulata
Asplenium decompositum
eburnum
fontanum
incidum
Microlepia novae-zelandiae
Onclea sensibilis
Woodwardia radicans
Platyloma falcatum

I have not recorded these as specially rare; but I do ask for attention to the fact that the Loquat, *Eriobotrya japonica*, quite a standard tree, *Lagerstroemia indica*, the *Theas*, the *Pittosporums*, *Ilex vomitoria*, *Primys Winteri*, *Rhododendron Falconeri*, the *Callicarpas*, *Mandevilla suaveolens*, and *Billardiera frutescens* have endured many winters unprotected in the shrubberies. I do hope, and all lovers of gardening will hope, that the present Earl of Ilchester will enable Mr. McNeil to extend the garden, and to give more space by judicious shiftings and arrangements to the many beautiful specimens suffering from overcrowding. They are truly worthy of the outlay.—G.

POMEGRANATES RIPENING IN THE OPEN AIR.—Mr. Dauhuz informs us that the Pomegranates have ripened this year out

of doors in his garden at Buckingham Villa, Ryde, Isle of Wight.

OKEFORD FITZPAINE IN THE AUTUMN.

I HAVE recorded my visit to my good friend Mr. Radclyffe in July, and I should now, at the close of this most trying season, just like to say what I have seen to-day (September 23rd); and you, my friend, who are mourning over your mildew and orange fungus, over puny growth and weakly shoots, who begin to think that Briars are after all doubtful, would only have to come here and have all your doubts confirmed, and go back and say, "Nothing but Manetti for me." I have been through all my friend's garden to-day, and everywhere the proofs of high cultivation, great skill, and thorough knowledge of all that he takes in hand are to be seen. Mr. Radclyffe holds the first place as a rosarian, if by that we mean one who thoroughly understands the nature and culture of the Rose—who loves it for its own sake, and not for the prizes which it brings. Well, all Rose-growers know how this season has "bothered" them, and in how many cases it has conquered their energies, and made them give up in despair all hopes of doing anything this season with Roses. But not so with my friend. "Never despair" is his motto; and so he has fought and fairly conquered his enemies. With knife in hand and scissors at his belt, he cut off all wilding shoots and mildewed leaves; while a bucketful of manure to a tree, and a gallon of water every second day to each, for seventy-five days of this broiling summer, supplied the moisture and vigour that the skies denied. And now what is the result? Clean foliage, shoots from 5 to 6 feet long, heaps of flowers all over his garden; blooms of Charles Lefebvre 5½ inches across, of Souvenir de la Reine d'Angleterre 5½; beds of Souvenir de la Malmaison a sheet of snow; and Triomphe de Rennes with corymbs of flowers that would not disgrace a stand at the best time of the palmiest year. I have been through many a Rose garden this autumn, and have seen thousands of Roses and plenty of mildew; but I have not seen—I say it advisedly—any plants to equal in vigour and beauty those at Okeford Fitzpaine. Mr. Radclyffe has added again to his rosery this autumn, and I expect his garden next year will be indeed a fine sight.

Mr. Radclyffe's three Peach trees at Rushton have often been noticed with approbation in the columns of THE JOURNAL OF HORTICULTURE, and I believe we shall have by-and-by to say as much of the Peach trees here. His wall is now covered with a number of young healthy Peach and Nectarine trees; and I was quite surprised to find that they were all denuded of their leaves—so much so that I thought they were dead, but found that they had been half cut off, and then syringed with water in which blue vitriol, in the proportion of two ounces to three gallons, had been dissolved. This had caused the leaves to drop off, and given the wood a fine opportunity of ripening. The blossom buds were all well developed, and a fair chance given to them. We had some delicious samples of that first-rate fruit, the Princess of Wales, raised by Mr. Rivers, to-day. It is one of the most luscious and juicy Peaches I ever tasted, and Mr. Rivers may well be proud of having raised such a fruit. It is not often that a prize is obtained by Peaches grown on trees the first year of planting, and yet Mr. Radclyffe was enabled to do this at the Blandford Show this year.

Another fruit here taken in hand is the Strawberry—indeed, has not Mr. De Jonghe dubbed Mr. Radclyffe the prime arbiter of the destinies of every new Strawberry? Here, assuredly, the Strawberry is well treated. Noble plants were to be seen on all sides, runners of this year making splendid growth, and well furnishing themselves to withstand the winter's frost. Dr. Hogg, Mr. Radclyffe, Cockcomb, Wonderful, Bieton Pine, Lucas, Frogmore Late Pine, and Rivers' Eliza were the sorts most grown, and with them Galande, Red and White Alpine, and Royal Hauthois. Nor is it for himself all this is done. I do believe his greatest pleasure is to send "Steevie" round to his neighbours with the well-filled dishes of fine fruit produced by such skill and labour, for nothing is done without high cultivation here; and whether it be the Peach, the Rose, the Strawberry, or the Potato, nothing is left to chance, constant care and liberal supplies of good food being provided for all his pets.

I have just mentioned the Potato, about which there has been such difference of opinion. Mr. Radclyffe has strenuously maintained that where the haulm was green then the tubers ought to be left. We examined some to-day treated thus, and the produce was wonderful—in one instance fifty Potatoes

from one plant, and from another 11 lbs. weight! and this, in such a season as the present, is a result by no means to be despised.

There are many more things that might be said about my excellent friend's garden, but enough has been said to show that what he advises he practises himself, and the results which he promises to follow from his mode of treatment are realised in his own garden.—D., Deal.

METEOROLOGICAL DEPARTMENT BOARD OF TRADE.

HAVING annually remarked the great superiority in quality of the second crop of Figs in a warm orchard house over the first, and having attributed it to the dryness of the atmosphere in the autumnal months, when the Peaches are removed from the house and syringing discontinued, I was curious to learn what was the state of the atmosphere in those places where the Fig out of doors attains its greatest perfection. With this object I referred to the tables furnished daily to the papers by the Meteorological Department of the Board of Trade, but the only place that fulfilled my requirements was Toulon. Great was my surprise to find that on every day during the last fortnight on which I have seen the tables, the wet and dry bulbs stood exactly at the same figure, though no rain was falling, which is absurd.

Now, these tables, coming out as they do from a Government office, are likely to carry great authority with them, and to be made hereafter the foundation of meteorological science. A medical man, relying on their accuracy, might forbid his patient going to Toulon, on the ground that it had a damper climate than any known locality on the globe. When Admiral Fitzroy was alive, I pointed out to him that the temperature recorded as of Dover was obviously too high, and he afterwards added a (°) to the figures. I inspected personally the position of the instrument, and found that, though sheltered from the direct sun, it received some reflected heat. Upon this I urged the Admiral to depute some competent person to visit the several stations, and to examine—first, whether the instruments were trustworthy; and secondly, whether they were rightly placed. An accurate observer is a third desideratum.—G. S.

LECTURE ON PARASITIC FUNGI AFFECTING PLANTS.

By TUFFEN WEST, F.L.S., F.R.M.S.

It may not be amiss to preface the following by a few introductory remarks on Fungi, the parts of which they are composed, and the way in which their presence may induce disease, either in vegetation or in animal life.

Fungi may be defined as plants of a low type, and of the humblest structure. Mushrooms, Toadstools, and Puff-balls are Fungi; so are the blue moulds of paste and of cheese, whilst brewers' yeast presents us with one of the tribe in its simplest form.

Fungi are almost universally present in decaying organisms. The multiplied observations of scientific men in various parts leave no room for question that they are the principal agents in inducing ferment-changes and decay. Many kinds infest plants, occurring principally on the under (or respiratory) surface of the leaves. When such occur in greater number than usual, their effects may prove of serious consequence to the gardener or the husbandman, and even may be sources of national calamity, when, as in Ireland, the produce of one kind of vegetable is too exclusively relied on for the staple article of food. The injury done to Vines by their parasite Fungus—the Oidium—will be in the recollection of all. As examples of these leaf-loving Fungi, readily accessible and familiar to most, may be named the one found on Bramble leaves, whilst it is almost impossible to take up a straw without finding brown spots on it (called mildew by the farmer). These spots are constituted by masses of spores of a minute Fungus.

The term mycelium is given to delicate transparent filaments, which represent the root fibres of higher plants; these are present in all Fungi. In favourable circumstances these threads become, by multiplication with repeated forking, much matted together, and are then called thallus. The structures bearing the fruit are in their simplest condition only short upright branches, but various forms, often very elaborate, are

assumed by combination of these elements. The fruits of Fungi are designated spores. Sporules, sporidia, sporidiola, are synonymous terms, and should be disused. At the ends and along the edges of mycelium threads it is common to find rounded or oval bodies, having much the appearance of, and commonly designated, spores, from which, however, they should be distinguished as being merely buds, here called conidia. The mycelium is so much alike in all cases that it is practically hopeless to seek to distinguish Fungi by any characters resident in this part of their structure. The place of growth and arrangement of parts due to this cause, furnish useful provisional characters. Dimorphism—the occurrence of the same plant in two or three different states—has been well authenticated in several Fungi, and is on good grounds suspected to occur in more. The occurrence in many plants of cutaneous diseases from the presence of parasitic Fungi is in itself a fact of interest, when it is remembered that certain of the skin diseases affecting mankind are due to the same cause. Is it possible that transplantation from one to the other may occur? The present state of science seems quite to favour such a view, and the subject has been thought to possess sufficient interest to justify its being thus brought before the notice of the profession.

The existence in many of the higher plants of diseases accompanied with parasitic Fungi, and unquestionably induced thereby, has led to the attempt to ascertain how far careful study of these plant parasites may throw light on some difficult questions connected with analogous structures found in certain diseases of the human skin. The greater simplicity in the conditions of vegetable growth, and the readiness with which its processes can be observed under the microscope, lead to a reasonable expectation that in time questions relating both to practice and to hygiene may be assisted in their solution by such study.

The epiphyllous Fungi attack plants entirely irrespective of the health of their "hosts," which, however, when attacked, manifest symptoms of irritation and ill health in various ways, due to chemical changes set up in them by the parasite, and altering their nutrition. "Redness and swelling" are with some very marked (e.g., *Æcidium compositarum* Lapsani, *Trichobasis beta*, *Aregma bulbosum*), and there are good reasons for supposing that heat is also a concomitant. These indications of suffering from the presence of the parasite correspond strikingly with the classical definition of inflammation.

The parts of plants are not always invaded alike; some—indeed, most of the Fungi in question—prefer to nestle in the tissues immediately beneath the cuticle of the leaves on their lower surface, others on the stems (e.g., *Puccinia graminis*, *Ustilago hypodytes*), whilst a few invade one or other of the parts composing the flower (smut and bunt).

The effects of the Fungi differ greatly on different plants, some of which are sufficiently hardy to recover rapidly; but the softer herbaceous plants, through sap-drainage and deterioration, are usually quickly destroyed. In their mature condition they occur on leaves of different ages, according to the genus, and, in some cases, the species. *Æcidium* in its different forms almost always inhabits the young leaves; the *Uredo* fruits mostly affect older leaves; the *Puccinia*, leaves whose most vigorous condition is past; and in two species, occurring on the stems respectively of Hemlock and Asparagus, the fruit is not matured until winter, after the stalks of the plants have been long dead. It is not yet quite settled whether the *Erysiphei* pass into the tissues; in their official condition (e.g., Vine-blight), they appear on the most vigorous leaves, and some pass to the state of mature fruit, with very slight, if any, visible disturbance to the tissues of their host. Plants growing near together are often attacked by the same species of Fungus. The explanation of the fact is easy. The spores from an infected plant of the previous year, or motile gemmae just thrown off by members of the genera *Cystopira*, *Peronospora*, *Oidium*, however brought, whether carried by the wind or by insects, present in the soil, in or upon the seed, do undoubtedly spread in the way of a contagion induced by pre-existing germs.

Care must be taken not to confound the action of true parasites with that of the Fungi appearing on dead or dying vegetable matter. The first grow with the growth of their hosts, and in their vegetative portion, die at and through their death; with some there are evident precautions to prevent premature injury to the tissues of an infected plant. The latter feed upon, and reduce to simpler elements, decaying matters

which would otherwise cumber the ground and even prove noxious: these belong to totally different tribes.

The parasitic Fungi are apt to recur with so much regularity year by year in the same spots that, when their habitats have once been found, a supply from the same place may at the right period be calculated on with tolerable certainty. The presence of fungus-mycelium may be readily demonstrated (if present) in the apparently healthy tissues of healthy-looking plants. Parasites of this class produce changes differing greatly in appearance according to the kind of plant attacked and the invader—hence red in some, sickly pallor in others, blackness followed rapidly by offensive decay in a third division. These appearances are so characteristic that the educated eye may often diagnose the kinds met with in a quiet stroll through country lanes, by their effects, with as much ease and certainty as in practice; the types of disease presented will not seldom betray their nature by their peculiar *physique*. Seasons largely influence the prevalence or scarcity of these Fungi; moisture favours their growth. As yet the present exceptional summer has produced large numbers, whilst some kinds, found but sparingly hitherto by me, have been abundant notwithstanding the heat and drought. Special meteorological conditions are known to largely influence their growth; a close still air likewise: hence their luxuriance often in shady spots, and on plants sheltered from the breezes by rank, thickly crowded herbage. The Fungi which attack plants placed in situations which are (for them) unusually moist (as Ferns in a wet Fern-case, or plants in a damp greenhouse) are quite different from those to which they would have been liable in their native habitats. It is doubtful if the feeble health of the vegetables have any direct effect in inducing the attacks of parasitic Fungi, as it is certain that intestinal worms develop when their germs are placed in favourable situations, and that the health of their hosts has nothing to do with facilitating access to such places. The state of weather favouring growth of the Fungi is unfavourable to healthy life in the higher plants; hence the rapidity with which the latter fall a prey to the abounding parasitic Fungi in unhealthy seasons. During winter the epiphyllous Fungi disappear, but the first fine days of spring rapidly call forth again their latent vitality; with the leaves they come, and with them disappear. A few (*Melampora*) which appear as "rusts" in the autumn continue their growth on the decaying leaves, in damp spots, on which, in the following spring, they are found to have attained to a higher type of structure. Evergreens are almost free from them; five only are known to be subject to their attacks in this country—all rare except perhaps the *Puccinia buxi*. This comparative immunity may be due in measure to the density of their cuticles.

It may be stated as a general rule that each species of plant has its own parasitic Fungus, except in some of the larger natural orders, as the Leguminosae, Compositae, &c., where the same parasitic Fungus will be found attacking many of the specific forms therein included. It is rare to find plants belonging to different natural orders attacked by the same species of Fungus. There are many species, and even genera, of plants which have not been ascertained to be liable to parasitic Fungi. It is difficult to suggest any reason for such exemption. Hairiness of the surface will favour the arrest of floating spores, smooth polished surfaces the contrary. As in the case of galls, so it is again here. An abundant supply of nutritive juices, with thin cuticle, favours their production: hence the mutual preference for young leaves, stalks, and twigs in a state of active growth and sap-circulation. It is well known that the cellular are the least specialised of the tissues of plants, the woody and vascular the most complex; and it may not be without interest to remark that the first stages of decay are attended by Fungi of the simplest types—*Fusarium*, *Penicillium*, *Mucor*, *Botrytis*—whilst the reduction of the more specialised tissues seems to demand Fungi of more elaborate organisation—*Sphaeria* (ascigerous Fungi with corneous envelopes), *Peizize* (naked ascigerous Fungi)—and in vastly greater variety of specific type. As during life one plant furnishes oil of lavender, a second quinine, and a third strychnia, so during life will the tissues of the Potato seem only adapted to nourish its peculiar *Peronospora*, Corn its *Puccinia*, Mint its *Æcidium*, yet after death will all alike be preyed upon by the same kinds of Fungus, and suffer alike.

There are 235 reputed species of epiphyllous Fungi described as native to Britain, but several of the supposed genera are now considered by the best authorities to be only transitory conditions, so that the number is certain to be eventually

much reduced. The following represent some of the principal types;

I.—ECIDIUM.

Fig. 1. — A: Spermogone containing spermatia ("sperm-cells"); B. "Spores," germ cells produced in special sheaths (peridia).

With this genus are associated three others separated only by slight characters—Roestelia, Peridermium, Endophyllum. Spermogonia freely produced, ultimate destination of the germ-cells unknown; it has been thought, and may possibly be so, that from them, on the same or other plants, Puccinia-fruits may arise.

II.—UREDINEI (Rusts).

Fig. 2. *Uredo*, spores developed within cells, afterwards free. 3. *Lecythia*, spores free, along with them elongated cells (paraphyses). 4. *Trichobasis*, spores free, often with a short peduncle attached. (Spermogones are known to accompany some of the forms).

Several of these are known to be, and perhaps all may be, conditions of

III.—PUCCINIEI.

Fig. 5. *Xenodochus* (grows on Burnet). 6. *Arcyria* (Rosaceae). 7. *Triphragmium* (Meadow Sweet). 8. *Puccinia* (Grasses). 9. *Uromyces* (Vetches).

Sperm-cells rare, but known to occur with some species. Podisoma and Gymnosporangium are associated genera, in which the Puccinia-fruits are imbedded in a tremelloid, gelatinous mass.

IV.—USTILAGINEI (Smut and Bunt).

Fig 10. *Ustilago* (Smut), sexual conditions unknown. 11. *Tilletia* (Bunt): a, spores, which on germination, b, emit a filament, at the extremity of which short branches arise—these conjugate in pairs (as with *Syzygites* and some Algae), after which union a secondary fruit, c, is produced.

The essential nature of these changes has yet to be ascertained.

V.—PERONOSPOREI.

Fig. 12. *Cystopus*: a, "spores," arranged in headed threads, at first subcutaneous, then external through rupture of the plant-integument; their contents undergo segmentation and afterwards become motile; b, sperm-cell; c, germ-cell: a filament is produced from the former, which becomes closely applied to the latter, whilst without investment, after which a strong warted coat is formed.

Both "sperm," and "germ-cells" grow immersed in the tissues of the plant.

Fig. 13. *Peronospora*: a, arborescent threads, external to the surface of the leaf, bear at their tips gemmae, the contents of which, after segmentation, become motile; b, germ-cell ("oo-spore"), immersed; sperm-cells??

In this genus, the most deadly in their effects on vegetation of the epiphyllous Fungi are comprised. Suckers, analogous perhaps to the tendrils of higher plants, occur on the mycelium of members both of this and the former genus.

VI.—ERYSIPHEI.

11.

Fig. 14. *Erysiphe*: mycelium creeping over the external surface of the leaf, and throwing up at intervals jointed threads. a, the contents of the joints after segmentation become motile gemmae; b, fruit borne externally, globular and bony in texture, containing within them asci (c) or "spore-sacs"; d, spores; e, appendages.

The immature conditions of Fungi in this order constitute the spurious genus *Oidium*, so well known in connection with the Vine disease. Sexual conditions obscure.

With regard to the Fungi found parasitic in diseases of the human skin, so much of their life history yet remains to be discovered that speculation on their affinities cannot at the present time be other than barren of result. The well-known

mycelium represents principally the vegetative system or root-fibres of the higher plants, whilst it is very doubtful if the so-called "spores" (sporules, or sporidia), have any claim to be regarded as other than gemme—portions of mycelium thrown off to spread the plant, but having no connection with true sexual reproduction or its results. The greatest care and patience will be required ere we can hope to learn their entire life history, sufficiently even to know if what we meet in the different affections be really true species, native to the skin—forms fruiting when growing on plants, but barren on the skin—or common moulds (*Penicillium*, &c.) vegetating in conditions unfavourable to the production of true fruit. Artificial growth in water, glycerine, or liquor potassæ (!) can in nowise imitate the conditions under which they occur naturally; growth on rice starch, having been successful in resolving some other cases of similar difficulty, appears likely to prove the best material for furnishing the requisite pabulum. Beale's carmine fluid has in some cases enabled me to trace mycelium amongst surrounding tissues in a very happy manner.

Puccinia favi resembles *P. grammis* so closely (to judge from the figures and descriptions given of it), that one is led to ask whether it be not more probable that spores of the latter may have occurred to its discoverer as an accidental concomitant with *favus*-crusts than that it should be so excessively rare as to have eluded all further search for seventeen years by an array of good observers skilled in the use of first-class instruments. The incidental notices of its occurrence by subsequent observers do not produce on the mind a satisfactory conviction that they have really met with what Ardsten described. Spores are abundant in the air at particular periods; is it not possible that a *favus* patient or two, engaged in threshing, or passing near a spot where this operation was going forward, may have got a few spores of the corn mildew on their skin, and so been the means, all unwittingly, of causing grave error? In such a view of the case, notwithstanding the eminent authorities who have regarded it differently, we must consider the *Achorion* as having no connection at all with the *Puccinia*. It seems not improbable that "alterations of generations" may occur—that is to say, that a certain point in development may be reached by a fungus on one plant, that the parasite may reach a further stage on a second plant under a different form, whilst maturity may not be attained until it have passed through a third or fourth stage, characterised in each case by a different outward condition, as well as involving a different plant each time as host.—(*Medical Times and Gazette*.)

PHYTOLACCA DECANDRA OUT OF DOORS.

ABOUT a fortnight since, while making a tour through the principal Belgian gardens, I met with a beautiful bush of the above growing in the open ground in a partially shaded situation. It was certainly one of the most interesting objects I saw, and the most skilful in-door culture would give but a faint idea of the splendour of the plant as seen by me. It was composed of at least fifty stems, upwards of 8 feet high, of a bright crimson colour; the foliage was very luxuriant, and of a dark healthy green, the whole being surmounted by numerous and immense spikes of its Grape-like fruit. I might add that it was growing in an amateur's garden, about six miles from Brussels, on a broad open plain; therefore, I cannot at all perceive why it should not be extensively grown out of doors, at least in the south of England.

I was told that the plant above-named had been in the same place for a great number of years.—W.

TASMANIAN APPLES.

I HAVE sent per ship "Harrowby" one ordinary bushel case, containing three varieties of Apples—viz., Sturmer Pippin, Pearson's Plate, and Scarlet Nonpareil. I wish to know how they will carry a long distance. They were gathered from the trees and placed at once in the case on the day the ship sailed (April 15th). I have great hopes of the Sturmer Pippin arriving in good condition.

The Apple trees are suffering severely from a blight, apparently arising from atmospheric causes. It is a fungus of the lowest order, destroying the young wood every year. In appearance it resembles the mildew of England, but it is not that. I have tried every remedy that I could think of, but without any apparent benefit. It would be useless to send

you a specimen of the blighted wood, for by the time it arrived the fungus would all be dead.—WILLIAM THOMAS, *Nurseryman, Sandy Bay, Hobartown, Tasmania.*

The case above referred to arrived on the 6th of August, 114 days after its dispatch. The Scarlet Nonpareils were all quite decayed, and the fruit of Pearson's Plate were for the most part either much bruised and partially decayed, or wholly so. The few quite sound were excellent samples of the variety, sweet, and tolerably good, but the briskness was gone. With regard to Sturmer Pippin Mr. Thomas's conjecture proved perfectly correct, for only about one-fourth of the fruit was damaged and decayed, the remainder being excellent samples so far as appearance went, but in flavour they were sweet, yet without the briskness which English-grown fruit of the same variety possesses; still they were very palatable, and were equal to the fruit which is hawked about the streets.]

POMOLOGICAL GLEANINGS.

SANDALLS PLUM.—Mr. Dancer, of Little Sutton, Chiswick, has just called our attention to this, as he terms it, "really good Plum." An opinion like this, coming from such a quarter, is entitled to due respect, Mr. Dancer being one of the largest and most successful cultivators of Plums for the London markets. The great merit of this Plum is its lateness. It comes into use in September, after nearly all our Plums are over; moreover it will hang on the trees after being ripe a very long time without cracking, thus prolonging its season and making it doubly valuable. Everyone knows what a nuisance it is that the most of our Plums crack and split when they are ripe, after a little rain; our great growers frequently lose hundreds of bushels from this cause. This variety, then, which resists the effects of the wet is quite a treasure. In size the Sandalls Plum is about that of the Orleans, in colour dark purplish violet, with a thick bloom, slightly spotted. The flesh is firm, reddish yellow or amber-coloured, clinging to the stone, juicy and pleasant, with a slight Damson flavour. It is, however, more suited for a kitchen variety than for the dessert. It is a moderate bearer. The tree is small-leaved and twiggy like the Damson, attaining a great size. It is one of the few Plum trees that make timber.

There has always been some doubt as to the correctness of the name, "Sandalls," given to this Plum. The variety was discovered at Fulham, and is known in the market gardens under that name only. We have never been able to trace its true history, or detect a synonyme.

—**STIRLING CASTLE APPLE.**—This, in the south of Scotland where we have seen it during the past month, is considered the most valuable Apple grown. It is not so well known in the south of England as its great merits deserve. It is one of the Hawthornden class, a well-known one. In appearance it sometimes resembles Small's Admirable; indeed, we have seen examples of it which could not be distinguished from that variety. Others, again, more nearly resemble the Wormsley Pippin. In all respects it is, however, a most excellent sort. At Hopetoun House and Bothwell Castle, where we lately saw them growing, the trees were loaded with fine fruit. It is rather over medium size, roundish, flattened, slightly angular near the eye, of a pale green colour, a little russeted near the stalk, with a flush of dull red on the sunny side. Flesh whitish, tender, with a nice briskness, which makes it agreeable to eat, although it is in reality a kitchen variety. It is fit for use in September, and will keep good until February. The tree is healthy, and a most abundant bearer.

—**CHARLES VAN MONS PEAR.**—We allude to this Pear in order to notice how extremely fine it has been this season. It very much resembles the Napoleon, but is somewhat larger in size, the flesh more yellow, and richer in flavour than that variety. It might, indeed, be called an improved form of Napoleon. We have never tasted it so fine as it has been this season from an open pyramid on the Quince. It was exceedingly rich and juicy. The tree is very hardy and robust, and bears well as a pyramid on the Quince.

DISTRIBUTION OF PLANTS.—We are requested to announce that the First Commissioner of Her Majesty's Works, &c., intends to have distributed this autumn among the working classes and the poor inhabitants of London the surplus bedding-out plants in Battersea, Hyde, Regent's, and Victoria Parks,

and in the Royal Gardens, Kew. If the clergy, school committees, and others interested will make application to the Superintendents of the parks nearest to their respective parishes, or to the Director of the Royal Gardens, Kew, in the cases of persons residing in that neighbourhood, they will receive early intimation of the number of plants that can be allotted to each applicant, and of the time and manner of their distribution.

REPORT ON NEW FRUITS BY THE AMERICAN POMOLOGICAL SOCIETY.

APPLES.

THE MARTIN APPLE.—Originated at South Salem, County Ohio. It was a seedling planted by James Wilson, and first fruited between 1815 and 1820; after which it was propagated by root suckers. No trees have been grafted from it away from the farm upon which it grows. The original tree is said to be very productive, and has borne crops for nearly twenty-one years in succession, since the present owner has occupied the farm. It is thrifty and healthy, and always full of fruit; foliage large, branches upright.

The name was given because a little boy named Martin discovered its good qualities, and frequently stole the fruit from the original seedling tree.

DUZENBURY APPLE.—Specimens from Dr. James Fountain, Jefferson Valley, Westchester County, N.Y., who informs me that it originated on the farm of Charles Duzenbury, of Phillips-town, Putnam County, N.Y. Tree a vigorous grower, a good keeper, and retains its flavour well; fruit of medium size, roundish conical; skin greenish yellow, shaded, and rather obscurely splashed with red nearly over the whole surface; flesh whitish-yellow, crisp, tender, juicy, mild, sub-acid, excellent; somewhat of the New-England Seek-no-farther flavour. Ripe December till April.

STYMUS.—A new fruit, introduced by Dr. Fountain, and originated on the farm of Jacob Stymus, Dobbs's Ferry, on the Hudson. It came up by the side of an old Spitzenberg Apple tree (the whole orchard being Spitzenbergs). Growth rather more upright, but resembling it; a good bearer; fruit of medium size or above it; oblate, inclining to conic; skin yellowish, shaded, splashed, and striped with light and dark crimson nearly over the whole surface, some of the splashes of purplish crimson; flesh of fine texture, whitish, tender, juicy, with a mild, rich, sub-acid flavour, slightly aromatic; quality, best. Ripe October and November.

MOTE'S SWEET.—A new, beautiful, white Apple, raised from seed by L. S. Mote, West Milton, Ohio; to whom we are indebted for specimens, and who says the tree is hardy, of moderate growth, rather spreading, and productive. Fruit large, roundish, oblate, slightly conic, angular; skin pale whitish-yellow, with a tinge of red in the sun; flesh yellowish, fine-grained, juicy very tender, with a rich, sweet, honeyed flavour. Ripe September.

DEMOCRAT, OR VARICK.—Received from George L. Conover, West Fayette, Seneca County, N.Y., to whom I am indebted for specimens. Origin uncertain, but supposed to have originated in the vicinity of Trumansburg, Tomkins County, N.Y. Tree vigorous, upright, and productive; fruit always fair; size medium, or above, roundish, conical, inclining to oblong; skin pale whitish yellow, rather faintly striped and splashed with light and dark crimson nearly over the whole surface; flesh whitish, fine-grained, sometimes slightly stained next the skin, very tender, juicy, mild, pleasant, sub-acid flavour. A fine dessert fruit, ripening from December till March.

CREEK.—Received of Daniel Engle, Marietta, Penn., who says it is a native of Hellam Township, York County, Penn., where it has been fruited to a considerable extent, and is highly prized on account of its quality and extraordinary productiveness. It derives its name from Crenty Creek. Fruit medium, or below, oblate; skin greenish yellow, thinly shaded, and rather obscurely striped and splashed with light and dark red; flesh white, fine-grained, very tender, juicy, mild, sub-acid; quality very good at least. Ripe November.

HICKS APPLE, OR BUCKRAM.—Introduced by Isaac Hicks, of Westbury, North Hempstead, Long Island, N.Y., who found it in a hedge about the year 1853, and says it has proved the most productive and largest very early sweet Apple cultivated in that section,—earlier than Sweet Bough, and more productive. Fruit large, roundish, or roundish-oblate; skin pale greenish-yellow, considerably striped and splashed with crimson; flesh

whitish, tender, moderately juicy, with rich, sweet flavour, slightly aromatic. Ripe August.

PARK.—Introduced by William S. Carpenter, of Rye, Westchester County, N.Y., who values it highly as an amateur and market fruit. It originated on the farm of Roger Park, town of Harrison, N.Y. The original tree is still standing, and about seventy-five years old. Tree thrifty, and quite upright in its growth, and bears large crops every other year; fruit medium, roundish, inclining to conic, angular; skin yellowish, shaded, and rather obscurely splashed and striped with light and dark crimson nearly over the whole surface; flesh yellowish, rather firm, moderately juicy, with a rich, mild, sub-acid, slightly aromatic flavour; very good. Ripe January to March.

FAMILY, OR M'LOUD'S FAMILY.—An excellent early Apple of Southern origin, received from P. J. Berckmans, of Augusta, Ga. Mr. Berckmans says it is a beautiful grower, bears enormously, always regular. Fruit smooth, ripening for six weeks,—the most distinct foliage of any of our Southern Apples; fruit rather large, oblate, conical; skin yellowish, shaded, striped and splashed with dull red over two-thirds its surface; flesh white, tender, juicy, with a very mild, pleasant, sub-acid flavour; quality very good, or best.

SLIGHT'S LADY APPLE.—A new seedling, raised by Edgar Slight, Fiskhill Plains, Dutchess County, N.Y., from the Lady Apple, and like it in every respect, except that it is double the size, and the skin a little more yellow and waxy, and comes into eating earlier in the season.

BRILL'S SEEDLING.—Raised by Francis Brill, Newark, N.J.; and he values it highly for market and culinary purposes. Fruit large, oblong, conic, angular; skin yellow; flesh yellowish, tender, juicy, slightly sub-acid. Ripe October, November.

CELESTIA.—Received specimens from L. S. Mote, West Milton, O. One of his new seedlings, which promises to be an acquisition. Fruit rather large, roundish, inclining to conic; skin pale yellow; flesh yellowish, fine-grained, crisp, very tender, juicy, with a rich, mild, sub-acid flavour, with considerable aroma; quality best. Ripe September.

PINE-CREEK SWEET.—Specimens of this fine sweet Apple were sent us by John Hamilton, of Jersey Shore, Penn.; and he writes us that it originated at Pine Creek, Jersey Shore, Clinton County, Penn., where the original tree is still standing. Fruit large, roundish, conical; skin pale whitish-yellow; flesh white, crisp, very tender, juicy, with a very rich, honeyed flavour; quality very good, if not best. Ripe October to November.

COCKLIN'S FAVOURITE.—Originated with E. H. Cocklin, of Shepherdstown, Penn., who describes it as a very fine dessert fruit; keeps well, and continues in use from September till February. Tree a beautiful upright grower, and very productive. Fruit rather small, roundish oblate, inclining to conic; skin whitish, with a thin shade of crimson in the sun; flesh white, fine-grained, crisp, very tender, juicy, mild, pleasant, sub-acid; quality very good.

FLAKE'S FALL.—Received from James A. Nelson & Sons, of Indian Run, Mercer County, Penn.; and they inform me that it originated near that place, and is a very profitable sort for market. Moderate, rather upright grower, great bearer, and a large valuable variety for that section. Fruit large, oblate, inclining to conic, slightly angular; skin yellowish, shaded, striped and splashed over the whole surface with light and dark crimson, almost purplish in the sun; flesh white, fine-grained, crisp, tender, moderately juicy, with a very pleasant, mild, sub-acid flavour, peculiarly aromatic; quality very good, or best. Ripe September to November.

PEARS.

EDMUNDS.—Originated with Eliphalet Edmunds, of Brighton, near Rochester, N.Y., and promises to be one of the best of its season. Tree a very strong grower; fruit medium to large, somewhat irregular in form, and surface uneven, obtuse, pyriform, angular; skin yellow, with slight nettings of russet; stalk very long, set in a shallow cavity; flesh fine, whitish, juicy, melting, with a sweet, rich, peculiar flavour, somewhat like Almond or Walnut; quality very good or best. Ripe middle of September to middle of October.

MARY.—Not having seen the fruit of this Pear, we give F. R. Elliott's description: "Raised by Christopher Wiegell, of Cleveland, Ohio, from seed of the Seckle. Tree upright, vigorous, an early and abundant bearer; fruit a little below medium in size; form generally globular, obtuse, pyriform, occasionally one-sided; skin rich, pale yellow, mostly overspread and dotted with bright, rich red, becoming deep next the calyx, and a little russet next the stem; flesh white, finely granulated, almost

buttery, juicy, sweet; very good; season before the Madeleine, or early to middle of July."

MARGARET.—Another of Christopher Wiegell's seedlings. "Its history the same as the Mary. Fruit medium size, oblong, ovate; colour lemon yellow ground,—when fully ripe mostly overspread with deep, dull red, small russet dots, and patches of russet; flesh white, finely granulated, juicy, vinous, sweet, and free from astringency. Season last of July and early August."

Other new kinds, such as Dr. Turner's, Dr. Shurtleff's new seedlings, Painter's Seedling, Howard, Richardson's seedlings, Clapp's new seedlings, and Hebe, are spoken of as valuable.

REEDER'S SEEDLING.—Specimens of this new Pear were sent us last fall by Dr. Henry Reeder, of Varick, Seneca County, N.Y.; and, judging from the fruit, we should think it of superior quality. Mr. Reeder writes that the tree is about twelve years old, and was raised from the seed of Winter Nelis; which tree grew near a Seckle, and is, no doubt, a cross of the two varieties. Tree healthy and vigorous, rather spreading in form, and an excellent bearer; fruit small to medium size, obovate, truncate; skin yellow, netted and patched with light russet nearly over the whole surface; flesh fine, juicy, melting, somewhat buttery, very sugary, sufficiently vinous, perfumed with musk, and slightly aromatic; quality best. Ripe November.

RUTTER.—An excellent late variety, raised from seed of Van Mons Léon le Clerc by John Rutter, of West Chester, Chester County, Penn. Tree a vigorous grower, an early and an abundant bearer; fruit medium size, obovate, obtuse, pyriform, angular; skin rough, greenish yellow, often considerably sprinkled and netted with russet; flesh white, not very fine in texture, sufficiently juicy and melting, with a rich, sweet, vinous flavour, slightly aromatic; quality very good. Ripe October and first of November.

ELLIS.—A new Pear, highly prized where known, and was raised by Mrs. Annie Ellis, of New Bedford, Mass., from seed of the Seckle. Tree a thrifty grower, very hardy, and an abundant bearer; fruit medium or rather large, obovate, pyriform, truncate; skin greenish yellow, considerably patched and netted with russet, and sometimes a shade of crimson in the sun; flesh yellowish white, juicy, melting, with a rich, sweet flavour, slightly vinous, and a little aromatic; quality very good, or best. Ripe October.

BRONX.—Specimens received from Prof. George Thurber, of New York, who writes us that it was raised by James R. Swain, of Bronxville, Westchester County, N.Y. about the year 1850. An upright grower, inclined to pyramidal; an early, regular, and abundant bearer. Fruit medium size, obovate, pyriform; skin greenish yellow, partially netted and patched with russet; flesh whitish, juicy, melting, with a sweet, slightly perfumed flavour; quality very good. Ripe from the 1st to the middle of September.

PLUMS.

FOOTE'S EARLY ORLEANS.—Grown from seed of Wilmot's Early Orleans by Asahel Foote, of Williamstown, Mass. Tree hardy, much more vigorous than its parent, symmetrical, bears heavy crops, and almost free from rot; fruit medium size, roundish, inclining to oval; skin deep black, covered with a blue bloom; flesh greenish, moderately juicy, with a sweet, pleasant, vinous flavour; adheres to the stone. Ripe from the first to the middle of August.

RASPBERRIES.

Many new varieties have been on trial; but the Clarke and Belle de Pallaun have given the most general satisfaction. The Clarke is claimed to be hardy; and, if it prove so, it will add to its value. Duhring, Naomi, and Mrs. Wood, are said to be valuable; and Charles Arnold, of Paris, C.W., has raised some seedlings that are said to be of fine quality and hardy. There are also several new kinds of the Black Cap family that are highly praised, but not fully tested.

BLACKBERRIES.

Kittatinny and Wilson's Early are before the public as superior kinds, and, so far as tested, are worthy of extensive trial; the Kittatinny being hardier and sweeter in flavour than New Rochelle, and equally as vigorous and productive.

BLANCHING CELERY.

I HAVE had some experience in blanching Celery with sawdust, both for exhibitions and for private use, and I never succeeded in keeping the Celery from rotting in such material;

therefore I differ from the remarks of your correspondent, Mr. Bartrum, in the Journal of the 10th ult.

I have used sawdust varying from six months to two years old, and I have found that as soon as it became saturated with rain the Celery began decaying.

I prefer sand to sawdust, for with me Celery keeps fresh much longer in the sand than I ever could have preserved it in the sawdust. Sand requires wooden boxes to keep it in its proper position, exactly in the same way as Mr. Bartrum describes.

I have also found peat earth an excellent material for blanching Celery. I believe peat blanches it whiter than either sawdust or sand, and the Celery in it keeps much longer.

In this neighbourhood (Blackburn), cottagers grow Celery to great perfection, and some of the leading growers among them use nothing but brown paper to blanch their exhibition specimens. The paper is put twice round the plant from the ground upwards as high as the Celery is to be blanched, and pasted up the side to exclude air. A handful of soil is put round the bottom, and the top of the paper is tied round. In this way they manage to grow and blanch Celery fit for either a nobleman's table or an exhibition.—L. BLACK, Blackburn.

WORK FOR THE WEEK.

KITCHEN GARDEN.

We never believe that we are so near winter until we are actually in October. You may see crops seeding, ripening-off, or falling into the sere and yellow leaf all through the summer, and yet think no more about winter than if everything was fresh. Hand-glasses should now be in proper repair for protecting Cauliflowers, and frames cleared out ready to receive Endive and many other things. Temporary hotbeds must soon be in requisition for *Asparagus*. Those who still adhere to the old practice of giving all sorts of rich manure to *Asparagus* beds in winter and spring when the plants are dormant, and neglect doing so in summer when they require it, will now have the satisfaction to see the tops fit for the hook or scythe, and the beds may be cleared now whenever hands can be spared for the work; but those who neglect them altogether in winter, and feed them the whole summer through, cannot tell when the crop may be ready for the sickle, for their beds are yet green. Carrots, no one, I presume, will now leave the crop of Carrots, Potatoes, &c., long in the ground, if only for the sake of having the ground dug over before wet weather comes on. Carrots, Parsnips, and Beetroot, keep well packed in sand or ashes in a dry room or cellar. These crops when taken up during dry weather, and stored away in a dry state, not only keep much better, but the ground is not injured by the operation of lifting, which is the case when they are taken up in wet weather, especially in stiff clayey soils.

FRUIT GARDEN.

After the fruit is all gathered there will be much work in the fruit room for some weeks, in arranging, naming, and storing the late sorts after they are ascertained to be quite sound. Large currents of air should be admitted during this time, but after the work is finished the fruit room should be kept close, and as uniform in temperature as circumstances will allow. The best time to transplant fruit trees is the next six weeks; but where this is impracticable the fruit trees ought to be ordered without waiting till the ground is ready, as they are sure to be good thus early, whereas if the order be delayed until the spring, the stock is selected from by so many other customers, that you must be content with what you can obtain.

FLOWER GARDEN.

The Heliotrope is the first affected by frost; many of our stove plants stand more cold than this. It may seem strange to some to have flower beds matted over to save them from early frosts; but it has been a regular practice in some places to save the plants in flower by such means, particularly the beds near the house, till the beginning of December, for it frequently happens after a night or two of early frosts that we have fine weather for some time afterwards. The great requisite in the winter management of plants is to have them well hardened off before severe weather sets in, so as to have them in a perfectly dormant state—that is, without any sign of growth, and to keep them as dry as is consistent with their not suffering from the want of water.

GREENHOUSE AND CONSERVATORY.

The finest plant that can be placed in the conservatory for the next twelve months is the *Luculia gratissima*, the earliest of

which is now about opening its delightfully fragrant flowers. The standard temperature here in winter is 45°; it should never exceed that by fire heat, and for six weeks after Christmas it should be kept at about 40°, and little or no air given for three or four months. With this treatment most of the half-stove climbers flourish and bloom as well as could be wished. *Stephanotis floribunda*, *Echites suberecta*, *Ipomæa Horsfallii*, *Combretum purpureum*, and many others are thus treated. About this time it is advisable to remove the soil from the stems down to the main shoots, and to replace it with charcoal broken small; this protects them from damp. The surface of the borders should be kept porous by frequent stirring, and no water should be given until the leaves begin to droop from want of it, and then as much should be afforded at once as will reach the bottom of the border. In a day or two afterwards a little dry soil may be placed over the parts watered, to lessen evaporation. On this principle all plants in a dormant state in winter should be watered, whether they are in borders or in pots, provided these are well drained. We scarcely ever miss a slight frost or two from the middle to the end of October, and we have all seen at times that if our plants and flowers had escaped this early frost, they might have gone on safely enough for a month or six weeks. Except in the case of very young and softwooded plants, few greenhouse plants are much hurt by a slight frost late in autumn. Two or three rainy days do them much more harm, and it is really a very bad plan to house these plants early. Nurserymen never consider some of their finer *Heaths* safe out of doors after August, and they house almost all their plants from the middle of September to the middle of October, but theirs are all young, and many of them have been much forced for propagation, and have hardly yet recovered from the confinement of the propagating house, so that they require early protection.

STOVE.

When stove bulbs are about done growing, water is withheld from them by degrees, till at last the leaves turn yellow and die off. The pots are then turned on their sides and placed out of the way on shelves near the glass; but when room is scarce, and the bulbs are at rest during the winter, they are often shaken out of the soil and put by in drawers in the seed room, or in a dry cupboard in-doors. Now the whole tribe of *Orchids* which rest for the winter, and more especially those which cast their leaves, may be treated after the manner of stove bulbs, and to those who find any difficulty in wintering them in the usual way, this is the safest plan. The winter-growing kinds, on the other hand, require now to be put nearer the glass, and all shading is of course dispensed with after this time. *Lælia superbiens* throws up its flower stems at the rate of an inch a-day, and they are now upwards of 2 feet high, and promise to grow much longer yet. Mr. Skinner says that "the flower stems of this most magnificent plant grow from 9 to 12 feet long, and carry from eighteen to twenty flowers each," and that its "native place, Chantla, is very cold."

COLD PITS.

All the *Roses* that are to be forced before Christmas should be pruned forthwith, and placed in different pits for forcing and protection; at any rate, let no more rain touch them this season, it chills and soddens the soil about their roots. A good way to begin to force *Roses* is to stir up the surface of an old *Melon* bed after removing the soil, and, perhaps, to add a few fresh leaves or some tan to create a mild heat of 80°; to plunge the pots in this, not to cover the frame for the first week, and then to begin by drawing the lights only half over the frame for the next week, and to draw them closer by degrees, but still leaving large portions of air till the flower buds appear. Moss and Cabbage *Roses* worked on free stocks of China breeds, will thus flower three weeks or a month sooner than others on their own roots or on the Dog *Rose*.—W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

Horn among all advancing crops, filled up every foot of spare ground with winter and spring vegetables, examined all plantations of Cabbages, Broccoli, &c., to destroy grubs, which are troublesome this season: banked up Celery with litter where it would not have been advisable to use much earth, but for this see previous weeks' remarks. The heavy rains have rendered watering unnecessary; the chief point to be looked after is the saving of water for next season. If this is not done we must blame ourselves, and gardeners generally, and not the season.

Salsafy and *Scorzonera*, often thought little of, come in this season as helps in the kitchen. To have them good the ground should be well trenched as for Carrots, and any manure given should be placed at the bottom to entice the roots to go straight down. *Salsafy* is almost as sweet and crisp as a hazel nut when well grown and well cooked.

Jerusalem Artichokes make a nice dish at this season when other vegetables are scarce. They will stand for years in the same ground; but to have them in abundance and good in quality, they should be planted every year like Potatoes. We have frequently so treated them, and can recommend them to those who prefer a waxy to a flour-ball Potato.

Celery.—We have had letters from several correspondents, and we will answer the pith of their inquiries by saying that a 4 or 6-inch litter-covering blanches as well as earth, and presents no inconvenience in the way of earthing-up and damping.

FRUIT GARDEN.

We have still a considerable quantity of fruit ungathered. We have taken in the most of our Margil Apples, and as yet they are as sound and as hard as bullets, and we are told that in some gardens they are nearly over, so great is the difference in different soils, thin gravelly soils bringing fruit much earlier to maturity than clayey and deep loamy soils. For instance, after using Williams's Bon Chrétien, the Albertine, and Ambrosia Pears, we have had to bring in the Marie Louise and Louise Bonne of Jersey with some forcing, whilst some of our neighbours have used these, and have none left. One of our friends has told us that his Margil Apples and Marie Louise Pears are gone. With us, as stated above, we are forced to bring them on artificially. We have stated previously, and we would state again the fact, that we have one tree of Williams's Bon Chrétien Pear, and a beautiful fruit it is. If left to itself the fruit would scarcely meet our wants for a week, so soon does it become "sleepy" after gathering when nearly ripe; but from that tree we generally have a month's supply, and even more, simply by gathering the most forward fruit, wrapping them in paper, and giving them a little artificial heat near the chimney corner. When there is likely to be a break, we adopt the same system with other Pears, as Marie Louise and Louise Bonne of Jersey, &c., and thus keep up a regular succession of sweet succulent fruit. The chief point in thus forwarding fruit that would otherwise be much later, is not only to give additional heat to it, but to prevent the moisture evaporating. When we are particular we wrap each fruit separately in paper, place all in a large pot, and cover thickly with paper, when we set the pot in a rather warm place. We have seen Apples and Pears ripened for use fully exposed in a hothouse; but by such a method there is the liability to lose the juices of the fruit, which is not the case when treated as above stated. Of course it would not do to forward much of the same fruit artificially. When properly forwarded a few weeks before the usual time, many connoisseurs have formed no idea that what they partook of was forwarded artificially.

Planting.—Where much fruit-tree planting is to be done the sooner the ground is prepared for the trees, or at least stations made for them, the better they will thrive; and could we have our way we should like to plant by the third week in October, or sooner if the leaves and buds were tolerably ripe. Now is a good time to select the trees, and in all cases where numbers are wanted it would pay to give something more not to draw the trees, but take them up carefully, and puddle the roots before packing them. Some nurserymen put the roots in damp litter, which is next best to puddling, and others just send them as they are in dry litter. The success of autumn planting depends partly on saving all the fibres, that they may grow at once instead of having them all dried up, and the plant being obliged to make fresh ones before the roots are able to supply the expanding buds in the spring.

ORNAMENTAL DEPARTMENT.

The same remarks apply here as to planting, whether in pleasure grounds or for permanent wood plantations and covers. The press of work in most gardens renders it difficult to commence this work in time, but the sooner that preparations are made for it the better will the plants succeed. As a rule, trees and shrubs planted even in November have double the chance to succeed as compared with those planted in February or March. Spring planting often does well enough when there is a moist spring and summer; but in such a season as we have had, nothing but the water cart—and that is out of the question when planting has to be performed on a large scale—could keep the plants alive. The money that was wasted in labour and trees last spring ought to teach a lesson. Never

was spring planting more unsuccessful, even under general circumstances, and the want of success was still more ensured in special cases by exceptional liabilities, which are not met with in autumn or early winter planting. Trees planted in February and March were soon exposed to a fierce sun and a dry atmosphere before a fresh fibre was formed to meet these drying effects, and in many thousands of instances the plants burst their buds and then slowly died. The money and the labour thus wasted in the past season will not have been spent in vain if the result demonstrate the propriety of early planting, so that the roots will begin to make fibres before the cart is sealed up by frost. In planting early in November there is no risk of having the roots killed by exposure to severe frost, as they are apt to be when large quantities of trees are sent from great distances in January or February.

The heavy rains of the past week have greatly injured the flower beds. On this day week the flower beds were fine, but the rains have dashed the flowers off, though still the beds are passable, more especially as the grass is so beautiful; and a fine lawn and neat firm walks do much to neutralise some deficiencies in the blaze of colour in the beds.

Proceeded with propagating and potting, as detailed last week.—R. F.

TRADE CATALOGUES RECEIVED.

Lucombe, Pine, & Co., Exeter.—*Select List of New and Rare Plants, Conifers, Ornamental Trees and Shrubs, and Roses.*
Charles Turner, Royal Nurseries, Slough.—*Catalogue of Roses, Fruit Trees, Coniferae, Hardy Trees, Shrubs, &c.*

COVENT GARDEN MARKET.—SEPTEMBER 30.

OUR markets are very steady, and supplies both of home-grown and foreign produce are well kept up. Soft fruits, such as Plums and Peaches, are nearly over, the latter being confined to the Salway and October varieties.

TO CORRESPONDENTS.

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

* * We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely to The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.*

BOOKS (*Anemone*).—"Florists' Flowers" and "Flower Gardening for the Many," give the information you desire. You can have the two free by post from our office for nine postage stamps.

EDGING PLANT (*C. T. H.*, Dorset).—Of the two variegated plants, we

prefer the *Polemonium caruleum* to the *Dactylis glomerata*, but we can hardly say which of the little *Alternantheras* is the best.

PHYSANTHUS ALBENS (*A. H. Tuckerm.*).—Your climber which is ripening a large pod is *Physianthus albens*, or White Bladderbloom. It is a native of South America, and usually cultivated in the stove. That it should not only endure our climate against a south wall near Bristol, but ripen its fruit there is very interesting. We think that the late tropical summer is the cause of its success. I have seen your *Hoya carnea* also fruiting in the greenhouse. Will you oblige us by stating whether the *Physianthus* has borne exposure to one of our winters, and if so, whether it had any protection?

PEAT CHARCOAL. (*An Old Correspondent*).—We do not know where this can now be procured. The most likely way to obtain it would be to write to Mr. J. Smithson, Messrs. Goulding's Manure Manufactory, Dublin. "T. K." (see page 79 of our last volume), stated, that being unable to obtain peat charcoal, he was induced to try common charcoal, and found it answered even better than peat charcoal. He also stated that he was unable to give the name of the party of whom he purchased it, but, perhaps, "The Charcoal Burner, Betchworth, near Welwyn, Herts," would find him.

HEATING A FERNERY AND PIT (A *Three-years Subscriber*).—A small space for a Fern house, if furnished with a vessel for evaporation, would injure neither the hardy Ferns nor the Rose. There will be no difficulty in heating your pit from the large kitchen boiler, if the boiler is a close one. The boiler being so much below the level of the pit, it is in its favour. If you did do, we would be obliged to put it into the Fern house instead of having a separate one. Such hardy Ferns will do very well, however, without any heat, if the air be kept still under glass in winter; but a fire would make it all the better and more pleasant.

ERECTING A SMALL VINERY (H. Mash).—If you do all your work yourself, of course you can do it at a very different cost from what you would pay when a tradesman has to come and travelling expenses, as well as wages, must be paid for. But we believe the materials can be had for such a price as you can afford. Then there is the carriage, and then there will be something of a stove, but then there is the chimney. A small cylinder heater that might heat your place can be had for 40s., but to keep on the safe side, you would need one costing 41 mere. But for your wish for great cleanliness, as you must do your own stoking, for such a small house and only gentle forcing, we would have recommended merely a brick stove against the back wall, with a pipe and small chimney through and outside the wall, and cleanliness could be secured by having the feeding door outside the wall. This, at least, would cost a mere trifle.

ROSES FOR MARKET (Clemens).—"If you have bought the *Roses named*, it is of no use my saying anything about them. If you have not bought them, the following are the best of the summer *Roses* for your purpose, neat soil, and aspect. They are good *Roses*. La Ville de Bruxelles, Madame Socquet, and Charles Lawson, Chénodé, Madeline, Kean, Boule de Napoléon, and the two Bourbons Acidalie and Sir J. Paxton. Hybrid specimens of the Manetti stock are quite as early as the summer *Roses*. The following are great bloomers, and fit for bouquets to send to market or show—viz., Jules Margottin, Baronne Prevost, Gloire de Dijon, Maurice Bernardin, Charles Lefebvre, John Hopper, Madame Victor Verhier, Baronne de Maynard (pure white, an unceasing and great bloomer), Souvenir de Dr. Jumais, Marchal Vaillant, Madame Boutin, Duc de Cazes, Sénateur Vaisse, and Prince Camille de Rohan. They are a noble lot.—W. F. RADCLIFFE."

TRANSPLANTING AND POTTING CAMELLIAS (S. F. DA.)—You may now remove the Camellias planted in a conservatory border, but it would be safer to do so at the end of February or beginning of March; if they are in bloom at that time the moving and potting may be deferred until the flowering is over. The plants being small, you can remove them without much disturbing the roots, preserving a ball to each plant. If removed now the flower buds will probably fall. The border should be well drained, also the pots. For soil use a compost of two-thirds turf cut about an inch thick, from an old pasture where the soil is a good, rich, rather light loam, and torn into l-inch pieces. The other third should be fibrous sandy peat. In potting the compost should be made rather firm, and the surface finished off with a little finer soil. The compost should be used fresh. It would not hurt Heaths and Epacris to repot them now, but unless you have some particular object in view it would be better to defer doing so until March.

doing so until March.

WINTERING COMMELINA CELESTIS (Berks).—We have splendid beds of it. We treat it as a hardy perennial, merely giving early in November, or after the first severe frost, a top-dressing of leaf mould 2 or 3 inches thick, and whether the plants are from seed or from the old roots we have a splendid bloom. They do much better in this way than when taken up, but we take up, and place on a shelf in the greenhouse. They are kept tall and sandy during the winter, and when they begin to grow are supplied with water more copiously. You may keep the roots in dry sand during the winter in any place secure from frost, and in March they may be potted, placed in a frame or greenhouse, and planted out in May. A cellar is a good place to keep the roots.

APRICOTS FOR A SOUTH WALL (*Libani*).—Having Moorpark, you may add Keisha, earlier than it; Hemskerk, and St. Ambroise.

CULTURE OF BELLADONNA AND GUERNSEY LILIES (*Dromely*).—These bulbous plants should be kept in a growing state during the winter, and be placed on an airy shelf in the greenhouse, not shaded by climbers or other plants. They should be well supplied with water, but not in excessive quantity. The pots may be set on a pan filled with wet sand, which in summer should never be allowed to become dry, but when the foliage is mature the plants should have little water and full exposure to the sun's rays. Do not repot until the roots split the pots, or not often more than every two or three years. It is seldom the bulbs bloom the second year, or if they do so it is but sparingly, owing to their being disturbed the previous autumn.

TRIMULA FAFINOSA (*Stenhopa*).—It is probably the prettiest of the British Primroses, but is not suitable for an ordinary herbaceous border, though it will succeed in such if a little care be taken with it. It is best grown on moist ledges or rockwork. In a border it should have good drainage, a depth of 6 inches or more of pieces of stone being placed under it, and on the stones 6 inches of soil composed of light fibrous loam, peat, or old cow-manure refuse, with one-half grit. The situation

should be shaded from the midday sun, and the plant should be well supplied with moisture whilst growing in summer.

ECHEVERIA METALLICA PROPAGATION (R. E. G.).—You will best succeed by dividing the plant, taking off a few leaves with a portion of root. The divisions should be potted, and the plants, if possible, placed in a house where there is a brisk heat, keeping them moist and shaded until they are growing freely. It will be all the better if the pots can be plunged in a bath of from 75° to 80°.

CLEMATIS JACKMANI NAKED (A. Subscriber, Ireland).—Your plant of this beautiful Clematis should be cut down to within a foot of the soil; and to induce the production of more shoots, those starting from near the ground may be stopped when they have grown a foot or 18 inches. Training them zigzag will also cause the production of more side shoots.

LILIUM LANCEFOLIUM CULTURE (Idem).—It succeeds in an open border. Plant in November, cover the bulbs with about 3 inches of soil, and put a like depth of leaf mould over the place where they are planted.

TACSONIA VAN-VOLKEM FLOWER BUDS FALLING (A. Lady Subscriber).—We can only account for the flower buds falling by the plant not being trained near enough to the glass, and a deficiency of light owing to the Passion-Flower, and we imagine the soil is not sufficiently moist. The soil should be well watered, but not so as to saturate it. Weak liquid manure may be given once a week. For winter blooming do not prune, but thin out the shoots if too close, and train them about 6 inches apart, and from 6 to 9 inches from the glass. It ought to bloom well this autumn and winter. *Mandevilla suaveolens* is a fine climber. Train it near the glass, and keep it well watered. It is not a shy bloomer, all it requires is age and strength.

SEEDLING FUCHSIAS (G. T. M. Purvis).—Your double flowers appear to be of great substance, with a smooth outline, but not differing from many other double varieties. The single flower with long sepals is too coarse to be of any use.

REMOVING AND POTTING CARNATION LAYERS (An Ignoramus).—Your plants, if of the choice sorts, will be best potted and wintered in a cold frame, and be planted out in spring. If well rooted, the layers may, when detached from the old plant, be now planted where they are to remain.

HOLYHOCKS WINTERING (Idem).—The plants would be best taken up, potted, and wintered in a cold frame, the pots being plunged to the rim in coal ashes. Plant out in spring.

MANURING STRAWBERRIES WITH SEAWEED (Idem).—For plants in beds or rows, the seaweed may now be placed between the rows, and about the plants, in the same manner as manure. A dressing of this kind now, 1 or 2 inches thick, will be highly stimulating and enriching, and if a little fresh loam be placed on the seaweed, so as to cover it, all the better. Before applying the seaweed remove all weeds, runners, &c., and the space between the rows should be lightly stirred, merely scratching the surface. The seaweed ought not to be dug in.

PROPAGATING MAGNOLIAS (Cornubio).—Layering is the best mode of propagation. It may be done now or in spring. The layers take better when a slit is made about half way through the shoot, commencing the cut immediately below an eye or bud, and on the under side of the shoot. This part ought to be placed in the soil and securely pegged down. By next autumn the layers should be examined, if well rooted detached from the old plant, and planted out; but if not well rooted they should be left another year.

SHIELT FOR WISTARIA SINENSIS (Idem).—The *Wistaria* will not grow in the shade, nor will it succeed in the open ground. It requires a wall with a south or west aspect, and sheltered, and does best in soil dry rather than moist. It may, however, succeed if your wooden house faces the south.

QUINCE AND MEDLAR TREES (Idem).—In ordering, it is well to specify what kinds you require. Of Quinces, the best are the Apple-shaped and Pear-shaped; and of Medlars, the Dutch, but the Nottingham, though smaller, is better flavoured.

TROPEOLUM JARRATTI GRANDIFLORUM FOR A BAY WINDOW (E. Taylor).—It is a pretty climber, and will succeed trained near the glass in a bay window, if first be excluded. Now is the time to procure and plant it in a pot well drained, using for soil a compost of sandy peat one-third, and two-thirds sandy turfy loam. It is well to put in a rather small pot, and insert this in one of larger size, placing crocks at the bottom so as to bring both rims level, and fill in between the pots with soil. The plant should be rather sparingly watered until it is growing freely, then water freely, but not so as to saturate the soil.

CUTTING OFF A VINE STEM (An Old Correspondent).—If from your two-stemmed Vine you cut off one stem, the roots would not perish, but would increase the vigour of the remaining portion, provided you prevented bleeding. This may be done by removing the stem and branches after the Vine has grown a few inches in spring, or by applying Thomson's Styptic to the wound if the stem be cut at the winter pruning.

CLEMATIS NOT FLOWERING (Poplar).—Your plant growing very vigorously, it would appear that the soil is rich, and this circumstance will account for the plant not flowering. It will not flower freely until its vigour be subdued; but we would not check growth by root-pruning if the plant has a large space to grow over; but if limited, we would hit it in autumn and replant. You may, however, by keeping the branches or shoots closely secured to the wall, and at equal distances apart, and thin rather than thick, effect the better ripening of the wood, which we think will give you flowers in a year or two.

INARCHING ON A SWEETWATER VINE (J. T. N.).—We would prefer inarching a white Grape on a Sweetwater, but the kind must depend on the heat you can afford the Vine, as Royal Muscadine for the open air or a cool house; Marchioness of Hastings for a viney, if large bunches are desirable; and a Muscat, as Bowood Muscat, where heat can be given freely; or Trebbiano where late-keeping is considered an object.

SEEDLING PANST AND GOLDEN-LEAVED PELARGONIUM (G. McDermott).—Of the Rose, the whole of the petals had dropped and lost their colour. The *Panst*, *Katy Bell*, is good of its kind, very circular, but rather thin in the petals. The *Pelargonium* leaves are nothing new. It is unsafe to judge of the plant by a single leaf. A plant should be sent to judge of the merits of its foliage.

VINES UNFRUITFUL (C. J.).—It will help your healthy but unfruitful

Vines, with roots deep in the soil, to make a deep drain in front of the border. Take away as much of the surface soil as you can without injuring the roots, put on a couple of inches in thickness of sweet fibrous loam and some old mortar, &c., to encourage the fibres to come up. Entice them still more by keeping the border dry and warm by covering with 12 or 15 inches of dry litter, and keep the house drier and hotter with fire heat for a time now, as long as the leaves continue green. If the wood is rank and unripened, you will have but little fruit. If these remedies do not prove effectual—and the heating should have commenced in September—then the best plan next year would be to take up the Vines carefully and replant nearer the surface, after draining, &c.; but the above will often be successful.

VINES NOT FLOWERING (J. H. B., Dorset).—With a concrete bottom, we should think your Vine roots have not gone down too deep. The yearly surfacing perishes the idea of scarcity of food being the cause. If the border is not drained in front of the bed of concrete, there may be too much moisture at the roots, and that would prevent the wood being well ripened. The drain may make all right. Again, as the Vines, though refusing to flower, seem to grow well, try what a little more air and dry heat will do for them this autumn. We presume that the yearly dressings have not buried the roots too deeply; but if so, they will be better if replanted nearer the surface. If the roots are only a fair distance from the surface, we would try hardening the wood with extra dry heat now.

PRESERVING SCARLET PELARGONIUMS IN WINTER (J. Beresford).—The best plan of keeping Scarlet *Pelargoniums* hung up in a cellar, is to shake all the earth from the roots, prune off all the soft parts of the plant, wrap the roots in moss slightly damp, and hang them up. They will do best in a dry cool cellar. They will need no attention until they begin to break all over the old stems in spring, when they must have light and air, and if put into small pots all the better. Of course some will die, but many may be expected to live. We think if the plants are pruned of all soft parts, all foliage removed, the roots also cut-in to a length of 6 inches or so, and these roots packed firmly in large pots or small wooden boxes, the *Pelargoniums* will keep better still. A 10 or 12-inch pot will thus hold a good number of stumped plants. Very little of the late summer's growth should be left, as it will be sure to decay. It is well to dip the top of the plant in dry lime or wood ashes, as it prevents the juices bleeding. A hay loft or garret, where a little light can be given in mild weather, is even better than a cellar.

CULTURE OF OUT-DOOR VINES (J. Reader).—*Esperance* will suit you best for the open wall, and the Black Hamburgh would do well in your warm sheltered position thirty miles south-west of London for a low wall, say 6 or 8 feet in height. We prefer the rod system of training, though spurting does well enough. For a high wall there may be several rods if that plan be adopted. The spurting mode will require less trouble in the management. Of the list of Grapes given, we would plant in your sheltered place only the Black Hamburgh and the *Esperance*. You would be less likely to ripen the *Barbarossa*, &c. If you fancied a white Grape you might use Royal Muscadine or Buckland Sweetwater. We have ripened the Dutch Sweetwater very well in and near London.

TIGHTENING WIRES FOR CORLONS (Reader).—Common thumbscrews may be found in any ironmonger's shop. They are greatly used by bell-hangers. We recommended them as being the easiest to procure. A thumbscrew is like a common screw, with an eye at one end for fastening the wire to. Place this screw through your already fixed support, and then, with a nut on the thread, the wire may be tightened with the thumb and finger—hence the name. There are many ways, however, well known to every worker in iron. The French use some very neat little things for this work, called stretchers or tighteners. You may train your trees in any form you please; for diagonals, however, the wires should be closer together.

CLIMBING ROSE (Poplar).—The best hardy climbing Hybrid Perpetual Rose is *Luc de Clugny*. It flowers freely and continuously, early and late. We cannot tell from the leaves sent what your Rose is. The stronger a wall Rose grows the less should it be cut. Next spring merely take off the points of the strong shoots to a good eye on sound wood. However good a climbing Rose tree worked on a Briar may be, it should be cut to three or four eyes the first spring after planting. It will ultimately become more successful than if the whole plant were left untouched. Manetti Rose plants need not be cut down. Mr. Kadylye never cuts down his Manetti Roses to the stump, unless there is a cause. Prince Camille de Rohan would make a fine dark wall Rose, but it is much given to mildew.

PHASEOLUS CARACALLA (A. M. G.).—This is called the Snail-flower and Caracal, in consequence of its hooded flowers, which are large and showy, in colour purple and yellow mixed. It is believed to be a native of Brazil, whence it was brought by the Portuguese, who gave it the name of Caracalla, which was also applied to a hooded dress worn by the ancient Gauls. The plant is often grown in southern Europe, South America, and India. It is easily cultivated in rich sandy loam in a cool stove, but, like all the tender Bean tribe, it is liable to red spider. In such a summer as this has been, we would expect the plant to do out of doors for a few months. Your *Ipomoea* seeds, from Buenos Ayres, are not likely to stand the winter out of doors.

VINE ROOTS DISEASED (A. J.). The top spit from the pasture, and mortar rubbish, and a few boiled bones, would have been safer than peat, straw, leaf mould, and half-rotten dung. The soil should also be examined for spawn of fungi. We fear that the roots are attacked with fungi or mildew. We can hardly think that the roots can be suffering from wet, as the border is floored and drained, and this has been a peculiarly dry season. Of course, we conclude that the roots have not been dried with the drought. If the roots are injured by fungi you might work in about 4 lbs. of flowers of sulphur in the border, and six bushels of shelled quicklime, allowing it to go in for the depth of an inch or two. If that do no good, we fear you must remove the soil, and use what will be less likely to produce mildew.

SEEDLING APPLES (James Cathach).—No. 1, which is below medium size, is a pretty-looking fruit, with a hard and rather dry but sweetish flesh. It is not rich enough for dessert, and we do not think it would cook well. It will, no doubt, prove an excellent keeping sort. No. 2, seedling from Nonington Wonder (Hammond's Seedling), has very much the appearance and character of its parent. The eye is close, and the fruit somewhat angular; these are its only distinctions. In our opinion it is inferior to Dame's Seedling.

NAMES OF FRUITS (H. G.).—Your Grape is the Black Hamburgh. (G. Y.).—We had to pay 10d. carriage for your parcel. (A Subscriber).—We had 6d. to pay for carriage to our office. If we receive the above amounts in postage stamps we will endeavour to name the fruits. (H. C.).—Apple: Lemon Pippin. The Pear was quite decayed. (A. Y.).—Apple: Munche's Pippin.

NAMES OF PLANTS (A Country Subscriber, Eastwood).—*Bryonia laciniosa* (*Disciplinus Mibneri*).—*Crataegus crus-galli*, var. *ovalifolia*. (A. C. W.).—*Cyclamen neapolitanum album*, *Viburnum plumbaginoides*, *Alchemilla alpina*, var. *conspicua*. (An Old Subscriber, Cardiff).—*Aspidium lonchitis*. (S. Bryon, Dudley End).—1, *Athyrium Filix-foemina*; 3, *Lactuca dilatata*; 4, *Nephrolepis exaltata*; 5, *Adiantum tetraphyllum*; 6, *A. adline*; 7, *A. hispidulum*.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the week ending September 29th.

DATE.	BAROMETER.		THERMOMETER.				Wind.	Rain in inches.	GENERAL REMARKS.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

THE BIRMINGHAM SHOW PRIZES AND ITS JUDGES.

HAVING seen a prize list for the approaching Birmingham Show, I was gratified to observe that several alterations and additions in enps had been made, which will, no doubt, offer a stronger inducement to some persons than a mere money prize; and I anticipate that the results will prove the step to have been a judicious one. Poultry-exhibiting ought not, in my opinion, to be so much a matter of pecuniary profit as a useful recreation calculated to improve the respective breeds.

If I remember rightly, at the last Show the Committee, or the gentlemen deputed to appoint the judges, made an addition to the original judges, which in my opinion was quite a step in the right direction. I believe, however, that as a rule the majority of those who fill the office of judges at Birmingham seldom, if ever, exercise that function elsewhere—a course which I think is a mistaken one, as they cannot be supposed to be equally competent with those gentlemen who are constantly performing that duty. Among others I would mention Mr. Hewitt, who has filled that office in every part of the country; and considering that his appointment never fails to give additional confidence to exhibitors, I should very much regret to find his name omitted from the list on the occasion in question. I would also suggest, in addition, the name of Mr. Hutton. He has judged at several shows at which I have been present, and his decisions appear to have given very general satisfaction.

I would further recommend that, in the selection of judges, the choice should fall upon gentlemen whose position and life, and the character they have at stake, place them above temptation or suspicion. To appoint, as has lately been the case at some shows, persons who hold or have held the position of servants to, or are in any way dependant on parties in the habit of exhibiting, cannot fail to be unsatisfactory to the majority of exhibitors; for however impartial their awards may be, the same confidence will not be placed on them as on persons whose position and circumstances furnish a stronger guarantee for independent judgment and action.—Cocern.

MANCHESTER POULTRY SHOW—ENTRY FEES.

I THINK your correspondent Mr. A. Heath, of Calne, has done good service by drawing attention to the early period for which the Manchester chicken Show is fixed. It is at least six weeks too early, as there are not many exhibitors who have convenience or opportunity for having many chickens (most early sittings do badly, this year's singularly so), hatched before April or May, and those hatched in these months will, of course, be unfit for exhibition, especially the larger varieties, for two months or so.

A uniform rate of entry per pen would lead to a much larger number of entries, as the present plan is only favourable for those who are able to keep several breeds—say 7s. or 7s. 6d. instead of 15s. for the first entry and 5s. afterwards, as many amateurs have only room for one variety, and perhaps are not

able to form more than a couple of good pens. I think the Middleton Show illustrates the advantage of this plan. There no difference is made on entering one or more pens, and the entry fee is regulated according to the prizes offered.—J. W. C., JUN.

I HAVE not yet seen the prize list of this Show, but read in "our Journal" the remarks made by Mr. Heath on the state in which birds must be at the date on which it is advertised to be held. I quite agree with Mr. Heath, and feel convinced that fanciers generally are of the same opinion.

My birds, with few exceptions, are now deep in moult. The few that are not will be so in eight or ten days; and the few young ones that are unable to do for themselves are being left by their parents, owing to the sickness which always prevails during the moulting season.

It was considered a matter of no small moment by the members of our Society (the North British Columbarian), to decide which was the best time for exhibiting Pigeons in perfect feather, and they came to the conclusion that December was the first month in which birds could be shown to advantage after moulting; but even then a few individuals are not perfect in the flight feathers, and until the feathers are not only fully developed but the quills hardened the Pigeon seldom recovers its wonted spirits.

If this question were fully considered by the members of Societies I think there would be fewer shows, if any at all, during the breeding and moulting seasons; and were the various shows to take place at the proper time—say from December to February inclusive—a greater number of entries would certainly be secured. Thus the numbers would be encouraged, and visitors be enabled to view the various breeds of Pigeons in all their beauty.

Manchester is a fine centre for a poultry and Pigeon show; and it is to be hoped that in future the show in that city will be held, as Mr. Heath suggests, "at least a month later." I venture to recommend two months later, as many delicate birds would by that time have a chance in the young classes.—JAMES HEIE.

POULTRY SHOW JUDGING.

To avoid partiality there should be two judges. A and B being provided with a pocket-book, A begins to judge at the first pen, and B at the last. They go on until they meet each other. The order is then reversed, B commences where A began, and *vice versa*. Having gone over each other's ground they compare their books; where they agree the prize is at once awarded, and where they differ it is either left to the decision of a third judge, or decided between themselves.—FAIR PLAY.

LONG SUTTON POULTRY SHOW.—We have just been favoured with a sight of the prize schedule of the Long Sutton Poultry Show, the entries for which close on the 3rd of October. Messrs. Hewitt, Teebay, and Tegetmeier are announced as the Judges. The prizes offered are liberal, and no less than four dozen classes are appointed. The prizes for every variety of Cochins, Brahmas, and Dorkings, for which there are separate classes, are £1 and 10s., but two silver cups, each of the value of five guineas, are to be awarded to the best pen. In Spanish

these money prizes are doubled. Hamburgs, Game, and any other distinct variety have £1 and 10s. prizes in each class, and prizes of £2 and £1 are allotted to Ducks, Geese, Turkeys, the Selling class, and also to a new class for any description of ornamental or song birds. In short, any variety of birds is in this class eligible for competition. The prizes for Pigeons are £1 and 10s., and in the portion devoted to local competition there are £5 5s., £1, and 10s. prizes. In all, thirteen silver cups are to be awarded. The new breeds of French fowls have one of these cups expressly for their own class.

THE FYLDE DISTRICT AGRICULTURAL AND POULTRY SHOW.

(From a Correspondent.)

This was held at Blackpool on the 15th of September, in two fields near the Poulton Road. All the departments were well managed by a very able and attentive Committee, and great praise is due to the Secretary, Mr. Rae. This being only the second Show, and seeing the great success it attained, I feel that it will become one of the first shows in Lancashire.

The poultry shown were of any age, and, as might be expected at this season, the young birds showed to the best advantage. There were some very good pens of *Game*, although the entries were not very numerous. The *Hamburgs*, as a whole, were not so good as I expected to see at a Lancashire show, and many of the young birds were very rumpy. The *Game Bantams* were a good and numerous class (twenty-four entries), and the "Any variety" class contained about twenty good pens. The first prize went to *Polands*, the second to *Black Hamburgs*, and the third to *Brahmas*. I should like to hint to the Committee to give another year a separate class to *Brahmas*, one to *Black Hamburgs*, and one to *Polands*. Even if the prizes were reduced, such classes would be more in accordance with the wishes of exhibitors, and the extra entries would pay the Committee well.

The *Duck* classes were of average merit.

I was pleased to see a class for ornamental water fowl, and although there were only three entries, no doubt they will increase another year: a pen of *Ruddy Shell Ducks* was much admired.

Mr. James Dixon, of Bradford, acted as Judge.

LEIGH POULTRY SHOW.

From a very small affair at its first institution, about eight years ago, the Show at Leigh has gradually increased in public estimation, until it ranks very highly among the poultry shows of Lancashire. This success, no doubt, is attributable to the very excellent arrangements of the Committee, and the staunch manner in which it has always adhered to the rules. Every year brings with it an increase in the number of entries; and in the quality of most of the classes this season, there was an improvement, more especially as regards those breeds of poultry most adapted for table purposes. The weather was delightful, and the number of visitors far exceeded that at former exhibitions. There was a drawback to the general appearance of the Show, arising from most of the adult birds being in very bad feather, and as chickens and old birds competed together, this circumstance gave a decided advantage to the former. It is but very rarely four such good pens of *Spanish* fowls compete together as those at Leigh; both for quality and condition they were unexceptionable. *Brahmas* and *Cochins* were also remarkably well shown. *Houdan*s were unusually good, and an extra prize was given to a large coop of twenty-four *Silver-spangled*, exhibited as extra stock. A very singular feature of this Meeting was, that the class for single *Game Bantam* cocks proved, without exception, so indifferent that no prize whatever could be awarded them. *Geese* and *Ducks* were well represented, and among the latter were to be seen the *Ruddy Shell Ducks*, the *Garganey*, and other choice varieties. A very handsomely-made cage, containing *Squirrels*, was exhibited, and musical bells were so arranged that the interesting little animals kept almost incessantly playing a variety of tunes, a feat we never before witnessed, the change of tune being entirely dependant on a change of rollers hidden from observation, striking the bells. The prizes were as follow:—

GAME (Black-breasted Red).—First, L. Biney, Manchester. Second, F. J. Ashbury, Enfield.

GAME (Brown Red).—First, C. W. Brierley, Middleton. Second, A. Haslam, Hindley.

GAME (Any other variety).—First, W. Painter, Abram. Second, C. W. Brierley.

SPANISH (Black).—First and Second, N. Cook, Chowbent. Highly Commended, T. & E. Comber, Middleton Hall, near Warrington.

COCHINS (Buff).—First, C. Sidgwick, Ryddlesden Hall, Keighley. Second and Highly Commended, W. A. Taylor, Manchester.

COCHINS (Any other colour).—First, E. Shaw, Plas Wilmot, Oswestry (Partridge). Second, J. A. Taylor (Partridge). Highly Commended, C. W. Brierley.

BRAHMA FOOTRA.—First, J. Sichel, Timperley. Second, E. Leech, Rochdale. Commended, J. Sichel; C. W. Brierley.

DORKINGS.—First, S. Farrington, Chat Moss, near Manchester. Second, C. W. Brierley.

HAMBURGS (Golden-pencilled).—First and Second, W. Parr, Patricroft. Commended, T. Wrigley, jun., Tonge, Middleton.

HAMBURGS (Silver-pencilled).—First, T. & E. Comber. Second, T. Wrigley, Tonge. Commended, H. Pickles, jun., Earby, Skipton.

HAMBURGS (Golden-spangled).—First and Second, N. Marlow, Denton. Highly Commended, S. & R. Ashton, Mottram; W. Parr, Patricroft; J. Chadderton, Hollinwood.

HAMBURGS (Silver-spangled).—First, H. Pickles, jun. Second, T. Wrigley. Highly Commended, W. Parr; J. Taylor, Withington Common. Commended, J. Wignall, Churnock Richard.

POLANDS (Any variety).—First and Second, P. Unsworth, Lowton. Highly Commended, L. Biney; S. Farrington; P. Unsworth.

GAME BANTAMS.—First, J. Henshall, Salford. Second, R. Gerrard, Atherton. Commended, J. Wignall; W. Parr.

BANTAMS (Any other variety).—First, N. Marlow (Black). Second, S. & R. Ashton (White). Highly Commended, S. & R. Ashton (Black).

ANY OTHER DISTINCT OR CROSSBRED.—First, J. Sichel (Crevé-Cœur). Second, L. Biney (Hondans). Highly Commended, C. Sidgwick (Black Hamburgs); W. Parr (Black Hamburgs); N. Marlow (Black Hamburgs); N. Cook, Chowbent (Crevé-Cœur); S. Farrington (Malay).

GAME COCK (Any variety).—First, P. Unsworth. Second, L. Biney.

GAME COCKEREL (Any variety).—First, A. Smith, Westleigh. Second, A. Haslam.

GAME PULLET (Any variety).—First, A. Haslam. Second, L. Biney. Highly Commended, F. T. Ashbury. Commended, C. W. Brierley.

SELLING CLASS.—First, J. Partington, Leigh (Silver-spangled *Polands*). Second, N. Cook (Hondans). Highly Commended, J. Taylor (Silver-spangled *Hamburgs*); S. Farrington (Black *Polands*); J. Morris, Bedford (Partridge *Cochins*).

EXTRA STOCK.—Extra Prize, J. Young, Astley (Silver-spangled *Hamburgs*). Highly Commended, W. Newell, Leigh (Rabbits).

DUCKS (Aylesbury).—First, E. Leech, Rochdale. Second, E. Shaw.

DUCKS (Rouen).—First, T. Wakefield, Golborne. Second, C. W. Brierley. Highly Commended, E. Leech. Commended, T. Barnes, Abram.

DUCKS (Any other variety).—First and Second, C. W. Brierley (Garganeys and Ruddy Shell Ducks). Highly Commended, J. Kilshall (Wild Ducks).

GESE OR *GOSLINGS* (Any colour).—First, E. Leech. Second, H. Ratcliffe, Fearnhead Cross (Toulouse). Highly Commended, H. Nield, Worsley.

TURKEYS.—Prize, E. Leech.

The Judge was Edward Hewitt, Esq., Sparkbrook, Birmingham.

AYLESBURY POULTRY SHOW.

This Show was held September 22nd and 23rd, in the new market, certainly one of the best places we have met with for the purpose. As might be expected, the *Ducks* and *Geese* were in great force, and very remarkable as to quality. Mr. J. K. Fowler came out with great force in *Geese*, and well deserved the first prize which was awarded, and he was closely followed by Mr. Stott, and Mrs. Seamons. In *Aylesbury Ducks* Mrs. Seamons was first and second, and Mr. Fowler third.

The following is the list of awards:—

YOUNG BIRDS.

DORKINGS (Any variety).—First, J. Lowndes, Grendon, near Northampton. Second, J. S. Lowndes, Hartwell, Aylesbury (Silver-Grey). Third, J. Smith, Pctworth. Highly Commended, D. C. Campbell, M.D. Brentwood (Coloured and White).

BRAHMAS (Any variety).—First, Mrs. Burrell, Stoke Park, Ipswich. Second, Lieut-Col. Lane, Bradnell Park. Third, A. P. Hurt, Alderwasley, Derby. Commended, C. Layland, Morris Brook, near Warrington (Dark).

SPANISH.—First and Second, M. Farrand, Dalton, near Huddersfield. Third, W. R. Bull, Newport Pagnell.

COCHINS (Buff).—First, Hon. Mrs. Sugden, Wells. Second, J. N. Beasley, Northampton. Third, H. Lingwood, Barking, Needham Market. Highly Commended, J. N. Beasley, Northampton; C. Sidgwick, Ryddlesden Hall, Keighley.

COCHINS (Partridge).—First and Third, B. S. Lowndes, Winslow. Second, J. K. Fowler, Aylesbury. Commended, Hon. Mrs. Sugden.

GAME (Black-breasted and other Reds).—First, H. Lee, Appuldurcombe, Isle of Wight. Second and Third, J. Fletcher, Stoneyclough, near Manchester (Brown and Black Red).

GAME (Any other colour).—First, J. Fletcher (Duckwings). Second and Third, S. Matthews, Stowmarket (Duckwings).

CREVE-CŒURS.—First, J. K. Fowler. Second, Col. Stuart Wortley, London. Third, Miss E. Williams, Hendley, Berwick.

FRENCH LOULS (Any other variety).—First, F. E. Peald, Whitmoor, near Nottingham (Hondans). Second, J. K. Fowler (La Heche). Third, H. M. Maynard, Holmewood, Isle of Wight (Hondans). Highly Commended, H. M. Maynard (Hondans); W. Barford, Aylesbury (Hondans).

HAMBURGS (Gold or Silver-pencilled).—First, S. Burn, Whitby (Gold). Second, H. Beldon, Goitstock. Third, F. Pittis, jun., Newport, Isle of Wight.

HAMBURGS (Gold or Silver-spangled).—First, H. Lee (Silver). Second, J. Laing, Cowburn, Spalding (Gold). Third, T. Walker, jun. (Gold).

GAME BANTAMS.—First, Rev. G. Raynor, Tonbridge (Black Red). Second, J. K. Fowler. Third, K. Swift, Southwell, Notts.

BANTAMS (Any other variety).—First, M. Leno, Dunstable (Laced). Second, H. Beldon. Third, C. Sparry, Dunstable (Silver-laced). Commended, Miss Hales, Canterbury (White-booted); E. Terry, jun., Walton, Aylesbury; T. Spary (Gold-laced).

POLISH (Any variety).—First and Second, H. Beldon.

ANY OTHER DISTINCT VARIETY.—First, C. Sidgwick (Black Hamburgs). Second, T. Walker, jun. (Black Hamburgs). Third, J. K. Fowler (Japanese Silkies).

DUCKS.—First and Second, Mrs. Seamons, Aylesbury. Third, J. K. Fowler. Highly Commended, Mrs. Seamons; J. K. Fowler.

DUCKS (Rouen).—First, T. Hollis, Reading. Second, J. S. Lowndes.

Third, J. K. Fowler. Highly Commended, E. Leech, Rochdale; J. Stott, Rochdale. Commended, F. Parlett, Great Baddow, Chelmsford.

DUCKS (Any other variety).—First, C. N. Baker, London (Mandarin). Second, F. Pittis, jun. (Black East Indian). Third, S. & R. Ashton, Mottram (Carolinas).

GESE (Any variety).—First, J. K. Fowler. Second, J. Stott. Third, J. Denchfield, Bursdon, Aylesbury. Highly Commended, J. N. Bensley, Northampton (Curled Sebastopol.)

TURKEYS (Any variety).—First, Lord Chesham, Latimers, Chesham. Second, E. Leech. Third, G. R. Pearson, Coltersworth (Cambridge).

PHEASANTS (Any variety).—First, J. K. Fowler (Kalege). Second, B. S. Lowdes (Gold). Third, M. Lemo (Gold). Highly Commended, H. Jones, The Pheasantry, Dinton. Ducks (Chinese); J. K. Fowler (Silver). Commended, J. K. Fowler (Gold).

DUCKS (Aylesbury).—Special Prize, a Silver Cup, presented by Lady A. de Rothschild, G. Maycock, Duddershall. Highly Commended, W. Weston, Aylesbury; G. Maycock; W. Weston. Commended, J. Haynes, Walton, Aylesbury.

The Judges were Mr. W. B. Jeffries, Ipswich, and Mr. G. S. Sainsbury, Devizes.

WATERFORD FARMING SOCIETY'S POULTRY SHOW.

The following awards were made at this Show, held on the 17th of September.

SPANISH.—First, S. Mowbray. Second, Sir R. J. Paul.

COCHIN-CHINAS.—First, Sir R. J. Paul. Second, C. Newport Bolton.

DORKINGS.—First, Sir R. J. Paul. Second, S. Mowbray.

HAMBURGS.—First and Second, S. Mowbray.

DUCKS (Aylesbury).—First, S. Mowbray. Second, C. Newport Bolton.

DUCKS (Rouen).—First, C. Newport Bolton. Second, S. Mowbray.

GESE.—First, P. Anderson. Second, S. Mowbray.

COLLECTION OF POULTRY.—Medal, S. Mowbray.

FANCY CHICKENS.—First, W. Joyce. Second, Sir R. J. Paul.

CHESHIRE AGRICULTURAL SOCIETY'S POULTRY SHOW.

This was held at Crewe on the 23rd of September, when the following awards were made:—

DORKINGS.—Prize, Earl Grosvenor, M.P., Calveley Hall:

SPANISH (Black).—First, J. Siddons, Winsford. Second, W. Wolley, Bunbury. Highly Commended, J. Dorn, Wharton, Winsford.

GAME (Black-breasted Red).—First, R. Ashley, Nantwich. Second, J. Platt, Swanlow, Winsford.

GAME (Any colour).—First, T. Whittingham, Batherton. Second, R. Ashley. Highly Commended, J. Platt; T. Whittingham.

HAMBURGS (Gold or Silver-spangled).—Prize, Mrs. Flynn, Harding's Wood.

HAMBURGS (Gold or Silver-pencilled).—Prize, W. Speakman, Duddington.

COCHIN-CHINA (Cinnamon or Buff).—First, T. Green. Second, P. Johnson, Rushton.

COCHIN-CHINA (Any colour).—First and Second, E. Tudman, Whitechurch.

BRAHMA POOTRA.—First, C. Leyland, Grappenhall. Second, J. Little, Chester. Highly Commended, B. Elches, Woodhouses.

DUCKINGS (Aylesbury).—First, T. Rigby, Barnhall. Second, J. Platt.

DUCKINGS (Rouen).—First, J. Beckett, Prior's Heys, Tarvin. Second, S. Allen, Acton Station.

TURKEYS.—First and Second, J. Balt, Oulton.

GESE.—First, T. Rigby, Barnhall. Second, C. T. Dean. Highly Commended, W. Glasford, Lostock Gralam.

JUDGES.—Mr. R. Teebay, Fulwood, and Mr. W. Wooley, Bunbury.

ALTRINCHAM POULTRY SHOW.

This was held on the 24th of September, and was well attended both by exhibitors and visitors. The following is a list of the awards:—

SPANISH (Black).—First, W. A. Taylor, Manchester. Second, T. & E. Comber, Warrington. *Chickens*.—First and Second, W. A. Taylor.

GAME (Black or other Reds).—First, L. Biney, Manchester. Second, R. Hardwick, Church Bank, Bowdon. *Chickens*.—First and Second, J. Platt, Swanlow, Winsford.

GAME (Grey or other Blues).—Prize, P. Norbury, Bowdon. *Chickens*.—First, P. Norbury. Second, J. Davies, Washway, Sale.

DORKING (Any colour).—First, E. Shaw, Plas Wilmot, near Oswestry. Second, C. H. Brierley, Middleton. *Chickens*.—First, E. Shaw. Second, A. B. Bailey, Wilmslow.

COCHIN-CHINA (Cinnamon or Buff).—First, W. A. Taylor. Second, J. Sichel, Timperley. *Chickens*.—First and Second, W. A. Taylor.

COCHIN-CHINA (Partridge or White).—First, C. W. Brierley. Second, J. A. Turner. *Chickens*.—First, J. A. Taylor. Second, G. Smith, Millington, near Altrincham.

BRAHMA POOTRA.—First, E. Leech, Rochdale. Second, J. Sichel. *Chickens*.—First and Extra, J. Sichel. Second, C. Leyland, Grappenhall. **HAMBURGH** (Golden or Silver-spangled).—First, J. A. Taylor. Second, A. Cowburn, Brown Edge, Lynton.

HAMBURGH (Golden or Silver-pencilled).—First, T. Wrigley, Jun., Tonge. Second, J. Parr, Barton-on-Irwell.

GAME BANTAM (Black or other Reds).—First, H. Goulden, Bowdon. Second, J. T. Smith, Altrincham. *Chickens*.—First and Second, P. Norbury, Bowdon.

GAME BANTAM (Grey or other Blues).—First, L. Biney. Second, P. Norbury. *Chickens*.—First, L. Biney. Second, H. Richardson, Altrincham. **BANTAM** (Any variety).—First, S. & R. Ashton, Mottram. Second, W. A. Taylor.

ANY DISTINCT BREED NOT NAMED IN THE SCHEDULE.—First, T. & E. Comber, Warrington. Second, J. Sichel. Extra, N. Parr.

GAME COCK.—Cup, P. Norbury.

GAME BANTAM COCK.—Cup, J. Whitehead, Carrington, near Altrincham.

TURKEYS.—First, E. Leech. Second, J. Sichel.

GESE (White).—First, E. Leech. Second, S. H. Stott, Rochdale. **GESE** (Grey).—First, E. Leech. Second, M. Newton, Oldfield, Altrincham.

DUCKS (Aylesbury).—First, E. Leech. Second, M. Hornby, Swanlow, Winsford.

DUCKS (Rouen).—First, E. Leech. Second, C. W. Brierley, Rhodes House, Middleton.

RABBITS.—First, C. Davis, Ashton-on-Mersey. Second, A. C. Sparkes, Oldfield, near Altrincham. *Short Ear*.—First, R. Buxton, Altrincham. Second, H. Schloss, Dunham Massey.

JUDGES.—Mr. R. Teebay, Fulwood; and Mr. T. Burgess, Burley Dam, Cheshire.

RAISING LIGURIAN BEES.

I HAVE a Ligurian queen sent from Switzerland this summer, but have only about one hundred Ligurian bees. I am very anxious to procure enough of the latter to form a hive which will be strong enough to live through the winter. Will any of your correspondents be so kind as to send me some Ligurian bees without a queen, so that I may join them to those I have? I will send a post-office order for the price of the bees.—I. M. W.

[Even if you are able to obtain Ligurian workers we doubt whether your chance of success with them will be much if at all greater than with common bees. The latter would, of course, be readily procurable at a time when so many are daily consigned to the brimstone-pit, and would answer every purpose, as an entire change in the population takes place in the spring. The most certain plan, however, would be to obtain a stock of black bees in a moveable-comb hive, and effect an exchange of queens in the manner and with the precautions described by Mr. Woodbury in No. 336 of our new series.]

AUTUMNAL UNIONS.

WHEN the most profitable way of managing bees is well and widely understood, the brimstone rag will be seldom used. The general use of it now indicates ignorance, not inhumanity. The great bulk of our English bee-keepers have yet to be informed as to the value of swarms in autumn—that is, the bees in the hives marked for honey. Hence their destruction by brimstone. If their value were better known, the art of uniting them to stock hives would be studied and practised.

A few words on the value of surplus bees in autumn. A stock hive of moderate size, weighing 30 lbs. or 40 lbs. in September, is worth 21s. If an extra swarm be united to it, say, 20,000 bees, its value would be 26s. at least. Thus stored with bees it is able to do heavy duty on the early blossoms of fruit trees, which yield honey of the finest quality in great abundance. Hives thus assisted with additional bees are, generally speaking, ready for swarming three weeks earlier than they would be without such assistance in ordinary seasons. Of course, some summers are more favourable for breeding bees, and less destructive to their lives than others. In such seasons extra swarms in autumn are less valuable, but I have no hesitation in saying that it is a stroke of good policy to unite them to stock hives in September. I have taken all the honey from twenty hives this month, the bees of which I have united to twenty-eight others kept for stock. If I had twenty more spare swarms I would unite them to the same twenty-eight hives. Hives in this part of the country are unusually weak in numbers, and, doubtless, many of them will, if they survive the winter, be comparatively weak and worthless next spring.

The art of uniting swarms is a very simple but important affair. It is easily taught and much more easily performed. Given a swarm in an empty hive, and a stock hive to receive it, both standing together:—About sunset blow some smoke from old fustian or corduroy rags into the stock hive, then turn it up and place its crown on the board, or ground. Pour some syrup—that is, sugar and water highly flavoured with mint, over the combs and bees. Then turn up the hive containing the swarm, give it a violent blow with both hands to make all the bees lose their foothold and roll in a helpless mass into the crown of the hive, and then in a moment tumble the whole swarm into the stock hive (on the top of its bees and combs), put it on its board, and the work is done. All this can be done in less than a minute, and if done as described above there will be no fighting and no failure. A thousand swarms may be so united without the destruction of a single bee. Bees know each other by smell, they know and attack strange bees by smell. When two swarms are brought together and married by minted sugar, the peculiar smell of each swarm and bee is lost or swamped, and a friendship lasting as life is cemented.

Sunset is the time recommended for the uniting of swarms for many reasons, the best being that other bees are at home, and, therefore, not attracted by the smell of the syrup.

In winter or very cold weather the work of uniting bees is best done by candlelight in a room or barn. The chilling of some to death is thus avoided. In this communication my business is not to tell people how to drive swarms into empty hives; but, a gentleman came to me this week to say, that he had been severely tasked for half a day to drive a swarm; the bees would not run, and it was a terrible job. I said if he had poured half a pound of sugar and water over the bees fifteen minutes before he began to drive them, they would all have run up in twenty minutes. He said, "That is another wrinkle," and he was thankful for it.—A. PETTIGREW, *Rusholme, near Manchester.*

HONEY HARVEST IN HAMPSHIRE.

We have had a very fair honey harvest in our neighbourhood this season, as you will see by the annexed statement. You will observe the early part of the summer was very much more productive of honey than the latter.

From one of my hives I took 52 lbs., from another, 26 lbs., and a swarm which yielded 17 lbs. Both these hives, and the next two, described as A and D, belonging to my brother, Mr. F. Crowley, are Gale's hives.

A			D		
No. of drawers.		Net honey.	No. of Drawers.		Net Weight.
June 11.	2	7 lbs.	June 1.	1	4 lbs.
" 15.	2	7 1/2 "	" 3.	1	3 1/2 "
" 23.	1	4 "	" 4.	1	3 1/2 "
" 24.	1	4 "	" 8.	2	7 "
July 21.	1	4 "	" 11.	1	4 "
" 23.	1	4 "	" 12.	1	3 1/2 "
" 25.	1	3 "	" 15.	3	12 "
Aug. 25.	3	7 "	" 20.	1	4 "
" 29.	2	1 1/2 "	" 24.	1	4 "
			" 29.	1	3 1/2 "
Total....		41	July 13.	1	3 1/2 "
			" 17.	1	3 1/2 "
			" 25.	1	3 1/2 "
			Aug. 29.	3	5 "
			Total....		64 1/2 "

From another, a this-year's swarm, 14 1/2 lbs., and plenty left for the stock.

Mr. Alfred Crowley, of Croydon, also took from one of Gale's hives over 40 lbs.—PHILIP CROWLEY, *Culverton House, Alton.*

FEEDING BEES.

EARLY in the spring I purchased a stock of Ligurian bees, but they have not swarmed; and as they killed off all the drones some time since, I quite expect there will be no attempt at swarming until next year. Fearing that the bees had not a sufficient quantity of honey laid up for winter consumption, I endeavoured to feed them with syrup made from white lump sugar, from the top of the hive (a moveable bar-frame one), by means of an inverted wide-mouthed bottle; but as it appeared to me that only a very few bees at a time could gain access to the syrup, I had made a zinc tray with a circular opening through the centre to correspond with that in the top of the hive, through which the bees might pass from the latter on to the tray. Into the tray I poured syrup, and on the syrup I placed a thin deal board (perforated with small holes, which were made with a red hot wire), so that the bees might walk over the board and feed without smearing themselves with the syrup. The tray of syrup when placed on the hive I covered with an empty hive. After doing all this I found they fed freely, and in large numbers, but unfortunately, on subsequently examining them, I found them between the sides of the tray and the covering hive, dead in hundreds. Can you inform me where I am at fault?—TYRO.

[There is no bee-feeder at all equal to the inverted bottle when properly managed, and yours must have been greatly mismanaged if only a few bees at a time could gain access to the syrup in a wide-mouthed bottle. We find the great stumbling-block in the way of the efficient use of the bottle to be a very prevalent but utterly mistaken idea, that it is necessary to take extraordinary precautions in order to prevent the food from flowing into the hive. Acting under this delusion the syrup is often boiled to too thick a consistence, but more often the bottle-mouth is covered either with muslin, or even calico of so close a texture that its pores become clogged with food,

and it thereupon speedily assumes a concave shape, which, when a piece of perforated zinc is interposed, withdraws almost its entire surface quite beyond the reach of the craving little tongues, the owners of which may be supposed to experience some of the unenviable sensations of Tantalus, as they protrude through the zinc, stretching and straining themselves in the vain attempt to appropriate the coveted food. It should be remembered that as a covering for the mouth of a feeding-bottle no fabric should be employed the meshes of which are less than a sixteenth of an inch in diameter, and if it be doubted whether under such circumstances food may not flow down into the hive, let the experiment be made with pure water in the open air, when it will be found that after the first rush caused by the bottle's inversion even water will remain perfectly suspended.

The mortality which followed the use of your float-feeder was not owing either to the zinc or the carbonised wood, but probably arose from the sinking of the float, an accident of no unfrequent occurrence.]

OUR LETTER BOX.

COST OF FEEDING POULTRY (A Beginner).—Your old stock—your breeding birds—appear to be seventeen in number. They should cost at the outside 4s. 3d. per week to keep. If they have any advantage of food or run they should cost less. When for an adult you allow 3d. per head per week, you have allowed a sum that is reached only by Cobins. They are large eaters. Your present stock of poultry amounts to 92. The expenses for two months are 36s.—4s. only over the average of 1s. per head for eight weeks—three halfpence per week. At this rate each fowl will cost 6s. 6d. annually—that is, each breeding bird. You have not chickens enough for the number of hens you keep. Your eggs should return 1d. each. It is throwing away money to keep Spanish fowls to lay large eggs to be sold sixteen for a shilling. Ducks are more expensive than chickens, and they are wasters. Your eggs at 1d. should make 27 13s. This would make the produce £16 lbs., and would, even against your expenses, show a profit. Try furly the diminution of the food, or bring the fowls to the allowance we have named.

POULTRY PLUCKING EACH OTHER (P. G.).—Are your fowls in confinement? We should imagine they are. What is their breed? We fancy they are Spanish. We have some that are in the state of nudity you describe, especially the cocks. They remain quite contentedly while the hens eat their feathers. We can only prevent it by giving them their liberty. The only treatment is cooling food. If they are watched narrowly it will generally be found it is one bird only that takes to the habit. He or she should be removed directly. The birds should be plentifully supplied with fresh earth, and growing grass if they have it not. They eat the feathers because they are in a diseased state of body, and feathers approach nearer than anything else to that which they crave for. It is consequently wisdom to make the greatest change possible in their food and treatment.

MARKINGS OF BRAHMA POOTRAS (J. G. P.).—Light pencilling is, as a rule, preferred, provided it be regular and free from white and yellow. The cocks should have either black or black and white-spotted breasts, light hackle and saddle, and black tails.

POINTS OF CRIVE-CEURS (N. E. R.).—We believe Judges are agreed as to the points of Crive-Ceurs. They should be top-knotted, bearded, short-legged, square-bodied, and as black as possible. Weight and size are very important. Pullets seldom have white feathers in the top-knots, hens often do. Light and yellow feathers in cockerels do not disqualify. Red ones do. The black birds will always be preferred.

SPANISH COCK (B. B.).—The loss of one eye from the incurable swelled face to which Spanish fowls are subject, does not render him in the least less serviceable for breeding purposes.

NORTHALLERTON POULTRY SHOW.—Mr. John White, of Warlaby, informs us that both first and second prizes for Dorkings were awarded to himself, and not to Mr. O. A. Young.

WOLVERHAMPTON POULTRY SHOW.—The date for closing the entries at this Show has been altered to Monday, October 5th.

POULTRY HOUSE (A Subscriber, Quodquecum).—If you enclose seven postage stamps with your address, and order "Poultry-keeping for the Many," it will be sent to you post free from our office. It contains a plan and description of the house you need.

CAPONISING TURKEYS (An Irish Subscriber).—We never heard of the barbarous and totally needless practice being applied to Turkeys, and we cannot give any information on the subject.

DEAD PIGEON (L. W.).—We cannot undertake to dissect Pigeons; but from the general appearance of the bird we think it died of roup, on which so much was published by us in our last volume. You will find a recipe for its cure in No. 359.

A PAIR OF PIGEONS (A Fancier).—Beyond any doubt by "a pair" is intended a cock and a hen, and whoever wins a prize with two cocks or two hens has committed a fraud. We have a letter on the subject from Mr. Fulton detailing the times he has been thus defeated; but we cannot publish his letter.

BEES IN A WALL.—MOVING HIVES TO A SHED (W. E.).—Part of the wall should be cut away, so as to get at the combs, which, with the bees, should be put into a frame hive in the manner indicated in reply to D. Williams, in page 218. We do not consider it advisable to remove bees from their stands in order to place them in a shed during winter.

TAYLOR'S AMATEUR'S BAR HIVE (Northampton).—Write to any of the advertisers of Hives in our Journal, Messrs. Sutton, of Reading, and Messrs. Lawson & Son, of 23, Budge Row, Cannon Street, London, sell the McIlhenny Lencantha seed.

AQUARIUM TROUBLES (T. O. J.).—We never knew gold fish eat the Valisneria spiralis. If they do, the only remedy is to place the plants at one end with a wire net before them. The film on the fish is often caused by the water being too cold. Drift sand should cover the bottom of the aquarium. We never employed snails as scavengers.

WEEKLY CALENDAR.

Day of Month	Day of Week.	OCTOBER 8—14, 1868.	Average Temperature near London.			Rain in last 41 years.	Sun Rises.	Sun Sets.	Moon Rises.	Moon Sets.	Moon's Age.	Clock after Sun.	Day of Year

14	W	Meeting of Royal Microscopical Society.	60.0	40.6	50.3	19	25	6	6	5	28	14	3

From observations taken near London during the last forty-one years, the average day temperature of the week is 60.7°; and its night temperature 42.3°. The greatest heat was 80°, on the 14th, 1861; and the lowest cold 25°, on the 11th, 1860. The greatest fall of rain was 1.00 inch.

THE POTATO CROP—SAVING SEED.

AT this time of the year, in ordinary seasons, the Potato crop, in the districts where it is largely cultivated, is naturally matured and ready for lifting and storing; this season, on the contrary, we find the crop in the full luxuriance of growth usual in the months of June and July. These remarks are applicable to the north-eastern counties, especially Lincolnshire, where the soil is suitable for producing Potatoes celebrated for their high quality. This extraordinary and unusual luxuriance is traceable to the long-continued drought during May, June, July, and the greater part of August. The crop was deprived of the essentials to its natural growth and increase. Its energies in this respect were arrested, and the ripening of the tubers already formed was accelerated, and in a great measure completed prematurely. The size of the tubers at this stage varied with varieties; none, however, except the earliest section, gave anything but a miserable yield. There was, therefore, no alternative but to leave them to linger on, and wait for the rain to carry them forward.

Towards the end of August the rain came, and vegetation at once burst forth with a vigour unprecedented in our temperate climate. The withered tops of the Potatoes raised their heads, and entered on the race as if to recover the time they had lost. It was too late, the Potatoes being already partially matured. Their next effort was to perpetuate their kind, and this brings them to the extraordinary state in which we now find them—extraordinary only inasmuch as the time and manner of their increase is unusual.

Different kinds of Potatoes present different aspects. I will divide the crop into three types, selecting them from kinds which are most extensively cultivated—namely, the Regent, the Irish or Rocks, and the Fluke. Of the many varieties grown most have something in common with those named, and they will thus afford sufficient data.

Fine cliff land in Lincolnshire, within sound of "Great Tom," was the principal place of examination.

The Regents being the earliest of the three, their tubers were larger than those of the other varieties when overtaken by the drought. They had swelled well after the rain, and on examination were found to be a comparatively-fair though by no means a full crop; the second crop, or supertubers which had sprung from these, were numerous, the largest being nearly of the size of Walnuts, and they were in rapid growth. What is to be done with the crop? Verdict: Take it up at once to secure quality, which will more than compensate for the increase in bulk produced by the swelling of the supertubers, and just in proportion to the length of time these are allowed to remain attached, just so will the crop proper deteriorate in quality. "But they must be stored in quantity, and their skins are not fast, will they not heat?" To avoid this contingency, adopt the plan of the Hon. A. Leslie Melville, a gentleman who for many years has given much attention to the Potato. His plan is this—For many days previous

to taking up his crops, if the skins are not fast he cuts off the tops. This simply stops growth, and the skins immediately begin to become firm. In ten days, or even less, they are in good condition for storing, and they must not remain much longer than this time, or they will commence growing again. Mr. Melville has adopted the plan this year with much success.

The Irish, or Rocks, are, perhaps, more extensively cultivated in Lincolnshire and the adjacent counties than any other variety. They were considerably smaller than the Regents when overtaken by the drought. Immediately after the rain they commenced the rapid production of supertubers. The first crop of tubers has materially increased in bulk, but not in the same ratio as its progeny. The two crops are now about equal in bulk. In this case I think it would be wise to make quality subservient to quantity of produce; therefore, instead of cutting off the tops or taking them up, I would leave them in the ground until the last moment of the growing season to increase bulk. The gross weight will increase much in a fortnight or three weeks, as they are now swelling more rapidly than at any previous period of their growth. Neither will the sacrifice of quality be great, for at their present size, even if properly matured, the sample would be very inferior.

The above remarks will apply also to Flukes, the second crop, or supertubers, of these being much larger in bulk than the first, or crop proper. On every account, then, it is advisable to let them remain in the ground to increase in size and weight. In quality for cooking purposes they must be inferior, but the second crop will be fine seed for next season's planting. The crop proper of this variety in many pieces which I have seen I pronounced worthless as seed; the energies of the tubers are already exhausted.

The question of seed generally is worthy of consideration. I have carefully examined many specimens from the crop proper. In many instances every eye had sprung, and produced one or several subtubers; in others, the finest and the best eyes only had sprung. Now, what more natural than that quantities of the crop proper should be put aside for seed as heretofore, and what more natural than the result of such seed should be disappointing? I have no doubt but that some of the tubers which have sprung their eyes will push forth collateral tubers, but the growth of these will be weak, and totally inadequate to insure a good yield. Some, indeed, will produce no top at all if planted, but will form a cluster of progeny which will merely subsist for a time on the scanty juices of the parent tuber. These results I have proved by actual experiment. It is, therefore, necessary that the tubers of the crop proper which are saved from seed should be carefully examined as to whether their eyes have not already pushed, and are thus in a partially exhausted state. I foresee a certain danger in this respect, and yet it is not a danger of necessity. Safety and certainty consist in selecting Potatoes from the supertubers, or second crop. These, where large enough, will, if ordinary care is exercised in storing, make fine seed.

There is an idea which is very general—namely, that

the second crop of tubers from which the skins slip when handled, will not keep and answer the purpose of seed, and it is consigned to the pigs accordingly. Nothing can be more fallacious than this notion. I have proved year by year for ten years consecutively, that Potatoes taken up in an unripe state to the extent of their skins slipping off with the slightest touch will, if carefully managed, produce crops in all respects fully equal—indeed, I am quite safe in going a step further and saying slightly superior, to the crops produced by seed which had been left in the ground to fully ripen before being taken up. On this point I am glad to see the experience of “UPWARDS AND ONWARDS” so entirely in consonance with my own.—J. W.

CAUSE OF FLAVOUR IN FRUIT.

A VERY short article in your number of September 24th, on the cause of colour and flavour in fruit, is so interesting that I wish to be allowed to make a few remarks on the subject, especially as it is in reference to a letter of mine upon “the orchard-house railway” in the previous week’s number.

Your correspondent “G. S.” attributes the superior flavour of fruit having the advantage of being placed quite in the open air, under favourable circumstances, to the non-permeability of glass to certain rays of the sun. It has been demonstrated that the sun emits three distinct rays—the actinic (or chemical, as “G. S.” clearly explains them), the luminous, and the calorific or heating rays. All these are employed during the whole growth of a plant in bringing it to perfection; though it is generally supposed that the actinic ray is most active in spring and upon the early-developed plant, the luminous in summer, during its period of growth, and the heating ray in the autumn, at the ripening period. Thus Nature economises her forces, and brings them to bear at the period they are most needed to perfect the works of her hand. It would be very interesting if “G. S.” would give us further information on this subject; for the time has come when we cannot long hope to carry out our schemes (in fruit-growing more than in other matters) by guesswork, but that they must be able to stand the test of science, and a clear reason be given for the *pros* and the *contras* of our operations.

I have no doubt whatever but that the intervention of glass does affect the actinic rays. Dr. Brewster, in the “Philosophical Transactions,” so long ago as 1816 (page 106), goes so far as to say that bodies will not radiate their heat through glass, and ascribes all the effects which are supposed to have been thus obtained to a secondary radiation from the glass, which becomes heated by the reception of the rays issuing from the primary source; at all events, it is not improbable that glass checks radiation as much as an opaque substance of equal thickness with the glass. This brings me to the question I wish more particularly to lay before your readers. Hitherto I have done little more than reiterate what has been stated by “G. S.”

The question of radiation at night and its influence on the growth and development of fruit, is not sufficiently recognised. The gardener goes to bed at night under the full impression (and he is right to a certain extent), that his plants are at rest also, or ought to be, and so dismisses them from his mind until the morning. But nothing is ever perfectly still in nature; a constant reaction is going on between day and night. In the day the luminous rays of the sun aid the leaves to decompose the carbonic acid gas in the air, which is absorbed by the trees, and takes the place of the oxygen gas they evolve; at night oxygen is absorbed, and carbonic acid to a certain extent given out. The radiation which takes place where trees have the full benefit of the open air at night, but not otherwise, greatly facilitates these natural operations, and tends to keep the trees in a healthy state. In the animal economy, which is only a higher development of the vegetable, we fully recognise the necessity of rest undisturbed, and of offering no check to the excretions, forming as they do as important an element of health as the secretions. We cannot, therefore, interfere with this radiation without materially affecting the natural functions of the tree. Experience, independently of science, tells us what a subtle agent it is in the growth of plants. A narrow coping, for instance, on the top of a wall is sometimes quite sufficient protection to save the early blossoms on our trees by arresting the radiation. Is it not fair to infer that the same coping will influence the ripening of the fruit in summer from the same cause? How much more the covering of a whole roof?

It may be said that the latter remarks involve a contradic-

tion in stating the valuable services rendered to the trees by night air and radiation, and in the next sentence recognising the necessity of interfering with them; but we must not lose sight of the fact that our subject has reference to Peach trees, &c., which are in an abnormal state in our climate. The object, therefore, should be to meet this difficulty by protection in spring and increased heat in summer when required, and at the same time to interfere as little as possible with the natural functions of the tree. As may be supposed, we find by experience that the more carefully this is attended to the finer will be the fruit in size and flavour, and the more luxuriant the foliage of the trees. Now, I venture to say that the “orchard-house railway,” as an assistant to the orchard house itself, is by far the best means to this end that has yet been brought forward. The labour it involves is so slight that every change of atmosphere, whether for retarding or advancing the growth of the fruit, may be taken advantage of all through the year without the slightest inconvenience; and under the guidance of a clever gardener such results may be produced as will fully satisfy him. The advantage of removing lights overhead have long been recognised by our best gardeners; but the advantages it offers are very inferior to the railway system, for these reasons—it interferes with the Grapes, which can now be grown in the orchard house without injury to the trees, but which require less ventilation and more heat than fruit trees; a roof fitted with moveable sashes would cost more money than the railway; the trouble of moving them would be infinitely greater; and when done the effect upon the trees would by no means be equal to the advantages of the free circulation of the air all round.

I have already trespassed too much upon your space, but hope to be allowed on a future occasion to give the result of some experiments I am making upon radiation, as immediately connected with the roots of fruit trees.—J. F., *Southacre Rectory, Brandon.*

THE IMPROVERS OF THE HOLLYHOCK.

MUCH has been written in your pages in reference to the improvement of the Hollyhock. England seems to take all the credit to herself, forgetting to introduce her canny neighbour, the Scot.

Better Hollyhocks were to be found in Scotland before either Mr. Chater or Mr. Paul were known as growers of that flower.

I hope some of our old Scotch growers, such as Mr. Foulis, of Fordel, Mr. Porro, and Mr. Foulis, of Woodhouselee, who exhibited and competed for prizes more than thirty years ago, will favour the readers of your paper with the history of their earliest productions.—D. G. M.

DARKENING THE COLOURS OF FLOWERS.

E. KING, *Spitalfields*, wishes for information upon “darkening flowers, the most suitable soil for Dahlias, also the best seed of Dahlias for producing a blue or black variety.” This vision of a blue Dahlia is one that has haunted a certain class of florists for a very long time. Such a flower would most certainly be a great acquisition, and the wish to possess one of that colour is rendered all the stronger by the almost utter impossibility of its ever being gratified.

The colours of flowers have been divided by De Candolle into two great classes, those having for their type yellow, which passes into red and white, but never into blue, and those having for their type blue, which passes also into red and white, but never into yellow. This first series he calls xanthic, the last cyanic, and of these Lindley has given the following analysis:—

Cyanic.	Greenish blue	Yellowish green	Xanthic.
	Blue	Yellow	
	Violet blue	Orange yellow	
	Violet	Orange	
	Violet red	Orange red	
	Red		

Of this classification a certain writer says, “It is found that a yellow flower may assume the colours of the xanthic series, but never become blue, and *vice versa*; and this rule applies to many genera. It is not, however, universal, as genera are occasionally found having both yellow and blue flowers, as *Tropæolum* and *Hyacinthus*.” The Dahlia belongs to the yellow division, and it is very doubtful if ever it will prove another exception to this all but general rule.

With regard to a black variety, that is a colour which, with two or three dubious exceptions, is all but unknown among flowers, nor would it be appreciated in a Dahlia otherwise than

as a curiosity, and some of the varieties we have are of a purple closely verging upon black.

If "E. K." wishes to raise new dark varieties from seed, it should be saved from the best dark sorts producing seed, which not one really good bloom out of twenty ever does. Sow the seed in heat about the end of March, and when the seedlings have two leaves place them singly in small pots, shifting into larger as required, and plant out in May in a border not very heavily manured, where they will flower during August and September. It is, however, only the grower of hundreds of seedlings who has the shadow of a chance of obtaining improved varieties, so that "E. King" would do well not to expect any very great success, unless he be prepared to make the attempt upon a somewhat large scale. For information as to the crossing, propagation, and general culture of the Dahlia see Vol. 1. of Johnson's "Gardener," and for lists of new sorts the catalogues of the leading florists.—*AYRSHIRE GARDENER.*

SOME ORCHARD-HOUSE TREES.

In a short article on growing Peaches and Nectarines in pots, I last year recommended the system of removing the trees out of doors during the winter, and incurred the censure of both Mr. Rivers and Mr. Pearson for so doing. The trees were wintered out of doors last year, at least they remained outside until the last week in January, and I cannot observe any difference either in their health or free-bearing qualities, and the fruit has been finer than I ever had it before.

My principal reason for removing the trees is that the orchard house may be kept gay with flowering plants, chiefly Chrysanthemums, during October, November, and December. The trees are all repotted or top-dressed now, and will be turned out of doors directly. The fruit ripened fully three weeks earlier this year than it has ever yet done at this place, and it has been larger. The different varieties of Orange Nectarines were especially fine, and Murrey Nectarine, which is not generally of large size, was 8½ inches in circumference. The earliest Nectarine is still Hunt's Tawny, which ripened on the 5th of August; fruit of Balgovan was gathered on the same day. This is an early variety, in every respect excellent, and worthy of extensive cultivation. Bowden a large variety, but which seldom colours well, and unless they do so Nectarines are not attractive, ripened on the 10th. Pine Apple and Elruge were ripe on the 11th; Violette Hative and Hardwicke Seedling came in on the 13th. The last to ripen, about the end of August, were Rivers's Victoria and Prince of Wales; both have a tendency to crack with me. I have a plant of the last-named variety in a 13-inch pot which carried three dozen fruits, and fully two thirds of them were cracked, some of them very badly. I do not grow the Stanwick, but I am unwilling to discard Prince of Wales, as it is of excellent flavour and very productive. I have been advised to withhold syringing after the fruit is stoned as a preventive.

A few weeks ago I saw a system pursued to prevent the Stanwick from cracking, which seemed to be very successful. Being on a visit at Balbirnie Gardens, near Markinch, in Fife, I observed a very fine crop just on the point of ripening. I inquired of Mr. Temple, the gardener at that place, the means which he employed to obtain such fine fruit, when he drew my attention to a notch cut under each of the fruit about half through the wood. By this method the flow of sap is arrested, and the fruit ripens perfectly without cracking. Mr. Temple also informed me that he prevents the cracking of the fruit in Chasselas Musqué Grape by the same simple method.

As to Peaches, the earliest to ripen this year was Early Beatrice, which ripened on the 2nd of July. The plant I received from Mr. Rivers was very small, but ripened perfectly two fruit, which were of good flavour. Early Rivers did not bear any fruit, but I hope to prove both sorts fully next year. Early York was the next to ripen, on the 16th; this sort is always to be depended upon, the fruit is excellent, and it always bears a good crop. Early Grosse Mignonne has been very fine, one would therefore suppose that it requires a considerable amount of sun to ripen it well; this ripened on the 25th of July. Dr. Hogg came in on the 2nd of August, and promises well; Royal George came in on the 5th, Bellegarde on the 13th, Violette Hative on the 17th. At the same time ripened Golden Rathripe, beautiful in colour, but worthless as regards flavour. Exquisite ripened on the 25th, a large, yellow-fleshed variety of excellent flavour. It was closely succeeded by Prince of Wales, of which I have not yet formed a very favourable opinion. Princess of

Wales and Walburton Admirable ripened on the 31st of August; both are excellent. The first two fruits of the last-named weighed together 19 ozs. After an interval of four weeks Salway ripens. Can no one recommend good Peaches to fill up the gap?—*J. DOUGLAS.*

MR. YATES'S NURSERIES, SALE MOOR, MANCHESTER.

AMONGST the sights I saw worth recording during my late visit to Manchester were the magnificent *Calanthes*, the large masses of *Cecogyne cristata*, and the *Eucharis amazonica*. No such plants in equal health and quantity can be found in any other establishment in the country. Whilst looking at the above plants in such luxuriant growth, one might almost imagine that, after walking with considerable difficulty through an East Indian jungle, he had suddenly stopped to admire large masses of bright green foliage growing out of what he might for the moment suppose to be heaps or clusters of large goose eggs, so large and bright are the pseudo-bulbs. Leaving this magnificent display of *Calanthe vestita*, we might fancy ourselves transported to the banks of the Amazon, where large masses of white flowers invite inspection, and on approaching them we find they are those of the beautiful *Eucharis amazonica*. A slight stretch of fancy takes us to Nepal, where we see masses of clear white flowers, with yellow or orange centres, resting gracefully on carpets of vernal green; these are the beautiful *Cecogyne cristata*. The above and a thousand other gems shine out conspicuously, surrounded as they are by natural objects in their wildest state of luxuriance, for there is no pretension to any elaborate system of horticulture. Here all the plants are grown as naturally as possible, and for the sake of the flowers they produce.

On the evening of the 28th of August, after a busy morning's work at the Manchester Exhibition, I found myself at Sale Moor, in company with several eminent horticulturists, who had been, like myself, invited by Mr. R. S. Yates to see his establishment. The evening, however, was fast closing in when we arrived, so that there was only time to note mentally a few of the objects; and I must say I was almost selfish enough to wish my friends, though I respect them very highly, were enjoying a treat somewhere else, so anxious was I to be alone, note-book in hand, with the view of furnishing the readers of THE JOURNAL OF HORTICULTURE with the mode of cultivating many of the plants so skillfully grown by Mr. Yates and his clever gardener, Mr. Plant. I was, however, enabled to gather the following from Mr. Plant respecting his mode of treating *Calanthe vestita* and *Cecogyne cristata*. This may be taken as a safe and reliable way of cultivating these beautiful plants, for on visiting Mr. Yates on one or two occasions while at Oulton Park, I was furnished not only with the mode of treating them, but also with a fine stock of plants.

The *Calanthe* is usually grown in pots well drained, in a mixture of peat, charcoal, and cow dung in lumps. This compost, Mr. Plant finds, does not suit them so well as a good, strong, rich loam and well-dried cow dung mixed. We will commence their treatment in April, after the plants have had their season of rest and are ready for the next year's growth. The first proceeding is to procure the soil for them. This should be in a nice healthy state, not too wet nor too dry, and should be frequently turned over in an open airy shed, so that it may be well sweetened before using; and none of the soil should be rubbed through a sieve, but should be carefully broken or pulled to pieces with the hand. The pots to be used should also be perfectly clean and porous, and after placing about 2 inches of drainage in the bottom they may be filled up nearly to the level of the rim with the soil, which should be pressed into them moderately firmly. The pseudo-bulbs may then be placed on the soil, secured by means of small pieces of stick pushed down into the soil by the side of each, and a small piece of matting placed round the neck of the pseudo-bulb and fastened to the stick. This will keep the bulbs from moving till they have struck roots into the soil, which they will soon do if placed in a temperature of 70°, and frequently moistened with a slight dewing from a syringe having a very fine nozzle or rose, but care must be taken not to wet the soil too much before the roots have taken possession of it. The bulbs should be kept as near the glass as possible. Three moderate-sized bulbs should be placed in a 32-sized pot—these will make a handsome mass.

About the first week in May, if all has gone well with them,

they will have well filled the pot with roots, when they may be repotted in a larger pot, in a compost similar to that in which they were first potted. Water should be used sparingly until they have filled the second pot with roots. If the atmosphere is kept moist, little or no water will be required until the pots are well filled with roots; after this the plants will bear water pretty freely, and as soon as the pots are thoroughly filled with roots the plants may be well supplied with moderately strong manure water three or four times a-week, or oftener than this if they are growing freely. This treatment may be continued till the end of September, taking care to give them on all favourable occasions abundance of air.

About the end of August, or early in September, the flower spikes will make their appearance, breaking out from the side of the bulb at the base.

At the time of my visit, Mr. Yates's plants were pushing out flower shoots, more like good strong heads of Asparagus than anything else. They were the most extraordinary lot of plants I ever saw, and there is no doubt they will throw up spikes more than 4 feet high, clothed with their pretty white and crimson flowers. Care must now be taken not to keep the plants too thickly together. They should be set sufficiently far apart to allow the air to circulate freely amongst them, and to give sufficient light to the young flower spikes, for if these are kept too much shaded before they grow above the foliage, they become very much weakened, and frequently damp-off. The finest plants at Sale were set on inverted pots on a flue near the glass. They had leaves, I should think, from 18 inches to 2 feet 6 inches long, and 3 or 4 inches broad at the widest part of the leaf.

About the end of September the plants are placed in a temperature a little cooler than that they have been grown in during the previous four months; and in order to preserve them in flower for the longest possible time, the atmosphere should be kept as dry as possible. I have known them to last in great beauty in a drawing room for more than two months.

During the winter, after the blooming is over, the pots should be turned on their sides, and the plants kept without water till it is time to start them into growth again.

No plant is more useful for winter decoration than the *Calanthe*, and no plant more easily grown if the above directions are properly attended to. Altogether, I should think I saw nearly two hundred pots of this lovely plant in the most luxuriant health.

Of the beautiful *Cecygne cristata* Mr. Yates has as many plants as would fill a good-sized cart. All one side of a large house was occupied with plants of it, many of which were 3 feet across, and they are covered with large white flowers early in spring. The soil they are grown in is a good fibrous peat; the pots and pans must be half filled with drainage, and the lumps of peat well elevated above the rim. The peat should be pressed moderately closely into the pans, and squeezed as firmly together as possible above the rim. As the plant extends its growth, fresh roots are emitted at the junction with the old and the new pseudo-bulb. After the plants have done flowering they are placed in a high temperature, kept well supplied with water, and frequent waterings with moderately strong manure water are afforded. The *Cecygne*, like the *Calanthe*, will bear a high and very humid temperature during the growing season; but as soon as the former has matured its growth it must have all the air and sunshine that can be given it, in order to ripen its pseudo-bulbs thoroughly, and during this time only sufficient water must be afforded to prevent the plants from suffering injury. From the end of August up to the beginning of March a temperature of 65° will be the most suitable. About this time the plant will commence pushing out its flower spikes, and the flowers will preserve their beauty a long time if placed in a cool dry temperature, similar to that recommended for the *Calanthe*.

Of the *Eucharis amazonica*, Mr. Yates also holds a very large stock and manages to have a supply of flowers all the year round. The plants are grown in a very warm humid atmosphere, and, treated in this way, are very useful and ornamental.

Mr. Yates's houses also contain numerous other kinds of plants, and the two or three houses set apart for the cultivation of Orchids are crammed with the most choice species and varieties of that most interesting order in the most luxuriant state of health. Much care is also bestowed on the cultivation of the *Camellia*, of which there is a very large stock of remarkably fine plants of the best varieties. These are also grown for furnishing out flowers. One or two very lofty houses

are planted with winter-flowering *Acacias*, *Chorozemas*, and various other New Holland plants. Beneath one of the *Acacias* we spent a very pleasant and instructive evening, and Mr. Yates very humorously described the origin of his Orchid fancy, and the failures and successes he had met with during a long series of years. There are besides two large Rose houses, several Fern houses, and in the open air many acres of ground are covered with the choicest specimens of Conifers, Hollies, Rhododendrons, &c. To do full justice to the fine stock of plants in this old-established place would take a long series of articles, and several busy days with pencil and note-book, but when I visit it again I hope to have more time to devote to its contents.

Leaving Manchester next morning for London, I broke my journey at Sheffield. This horribly dusty and smoke-begrimed place is the last in the world near which one would expect to see plants grown; yet at a very little distance from this region of smoke and dust Messrs. Fisher, Holmes, & Co. have a very fine and extensive nursery filled with a very choice collection of trees, shrubs, fruits, &c. I had but time to take a hasty glance of it. In running through a portion of the grounds I came upon a long row of the Lawton Blackberry. This was covered with fruit, had a very pleasing effect, and will, no doubt, become a useful addition to our fruit garden. In the glass houses there was a very fine collection of all the popular plants in cultivation; but in one house I was much struck with the beauty of a plant of *Lapageria rosea*, completely covered with flowers. There could not be less than two hundred fully expanded flowers on it, and Mr. Fisher told me the plant had been covered just in the same way all through the season. Two other houses which I entered were filled with Tricoloured and double-flowered *Pelargoniums*. They certainly formed one of the finest sights I have seen for a very long time. The Tricolours were splendid in colour, and the double varieties were the finest I have ever seen, showing what a valuable race of plants these are for conservatory decoration. There was to be seen the beautiful *Madame Lemoine*, far outstripping all the other varieties that were grown beside it, fine though they were.

I thought on leaving this nursery, if such great results as these can be obtained in such a region of sulphur, dust, and smoke, surely we in London ought not to complain, seeing that the climate of London is much more favourable to the growth of plants generally than that of Yorkshire.

I will state in conclusion, that the Manchester Botanical Gardens were looking well, and there had evidently been a very fine display of bedding plants. The contents of Mr. Findlay's plant houses were in fine health; and in the Victoria regia house I saw the finest plant I have ever seen of that most beautiful Lily. The leaves were very large and of great substance.—J. WILLS.

MR. STANDISH'S LAST NEW GRAPE.

THIS is the Early Ascot Frontignan, an amber-coloured Grape, with a fine Muscat flavour, the berry and bunch, as regards size and shape, resembling the Royal Muscadine. It is a free setter, very hardy and vigorous, and the earliest Grape I have grown, if we except the Chasselas Vibert.

This valuable variety came into my possession as follows:—

Mr. Standish, having heard of my introducing a new kind of glass structure for the protection and the earlier ripening of various fruits, kindly sent me on the 20th of August, 1867, a few cuttings of this new Grape, thinking it might answer well in these structures. These cuttings were sent to me under a promise that I would part with no plant without his permission, and this I intend strictly to adhere to. The cuttings, about the size of a small goose-quill, were grafted immediately on Black Hamburgh stocks. One on a stock of its own size has grown a rod of 12 feet in length, but it is the one grafted on a spur of an established Hamburgh I wish to call attention to. This had two eyes, very small indeed, and no one would have imagined that each eye could have produced a vigorous shoot and a bunch of Grapes. One shoot was stopped, but the other grew 15 feet in length, when it was accidentally broken off early in the season to 9 feet; it would otherwise have extended to 20 feet at least. The girth of this shoot is 1½ inch; the wood is ripe, short-jointed, and the eyes very prominent. Three weeks since the Grapes were dead ripe, whereas those of the Hamburgh, on which it was grafted, are not yet fully coloured.

I consider this a most valuable variety as far as I have yet had experience of it. With the protection of the upright hexagonal and octagonal glass cases, in which I intend cultivating

it, we shall have no difficulty in growing Grapes in the open air. I was so interested in this Grape that I went a long distance (to Ascot), to see Mr. Standish and learn his experience in its growth. I am happy to say that it is the same as my own.—OBSERVER.

SPRING FLOWERS AT THE ANTIPODES.

I SEND you a few hasty notes made this day (July 24th), in my garden, being what I may term "a spring day" for the first time this season. Our winter season seems to be fast passing away: however, I must not rely too much upon it, for past experience tells me there is no certainty of the weather here. My thermometer indicated out of doors to-day in the shade at noon 65°; the day being warm and cloudy as well, seemed to give my garden quite a cheerful aspect. I must state to you first, before I begin writing about flowers, that we have had up to the present time for our gardens a very severe and troublesome winter; very severe frosts with alternate days of rain, snow and hail, and loud thunder occasionally. We have had weather of all sorts when we little expect such, and generally very late spring frosts annually, to our great mortification when vegetation of all kinds is far advanced.

The following are my random notes of plants in and out of flower:—*Jasminum nudiflorum*, trained against my house, with some hundreds of yellow flowers opening and fully expanded. *Berberis aquifolium*, flowers nearly open. *Viburnum tinus* and *V. tinus lucidum*, going out of flower, had been in flower all winter. Snowdrops opened their flowers for the first time to-day; yellow Crocuses the same; Hyacinths, nibs just showing colour. Upright and spreading Cypress, Virginian Cedar, and Arbor-Vitæ, new male and female flowers nearly expanded, most of them shedding seeds out of the old cones. Botany Bay Myrtle (*Veronica*), with its beautiful azure blue spikes in flower all winter, in sheltered parts of the garden. *Buddlea salicifolia*, going out of flower, having been in flower all through the winter. *Amaryllis belladonna*, and *A. belladonna minor*, now growing vigorously after flowering profusely late last autumn; *Sternbergia latea* and *S. Chusiana* doing the same. *Nerine sarniensis*, now producing very healthy leaves after resting all winter. Yellow Primrose in flower all winter in a warm sheltered place. *Spiræa prunifolia flore-pleno*, little white flowers, nearly expanded, flowers profusely in this part of the world. Rosemary bushes very full of flower. *Pyrus japonica*, white and red, now in full flower. Common Box tree in flower beautifully. Flower buds of Fortune's Double White Peach, Almonds, and garden Peach beginning to swell.

Peach trees look very promising for a good crop again; I hardly ever knew them to fail here. *Dielytra spectabilis*, strong buds just protruding through the ground, promises to flower freely this spring. Double red and white Daisy had a few casual flowers all winter; a great number of fresh flowers now open. Double white Primrose. Oh! this is lovely, now profusely in bloom; single and double Wallflowers the same. Jonquils will be much better in flower in a few days. *Forsythia viridissima* now profusely in flower, like the nude-flowered *Jasmine*. *Ligustrum japonicum* has just gone out of flower, after having remained in flower all winter. Heartsease nearly all in flower, more or less. Alder, Birch, and Nuts now covered with catkins, but not shedding pollen yet. *Viburnum tinus lucidum* flowering again a second time; young berries on the old flower stalks. *Alaternus*, flowers not quite out. *Polyanthus*, one plant in flower. *Daphne pontica* and *D. mezereum*, the former in full flower and grows well here, but the latter is very shy with us from some cause; it flowers freely, but makes no growth. *Juniperus prostrata*, very full of berries. Double and single sweet Violets, flowers just expanding. Double red Anemones just the same. *Gilia tricolor*, in flower. Hardy annuals stand the winter well here. *Pyracantha*, fruit dead ripe on the plants, and the same with *Cotoneaster*. Camellias planted out in the open border have stood the winter well, and look very healthy. Bear's-ears, new leaves just unrolling. Cowslips, a few now open. We raise a great variety of them here from seed, self-sown on many occasions. This will end my list.

Fortune's *Cryptomeria*, his Cypress, and his *Weigela* thrive well here. Besides these three, I may add his double Bindweed, *Calystegia pubescens*, and the rest of his plants from China which I have enumerated. I had the pleasure of seeing all Mr. Fortune's plants which I have written about, his Mountain *Pæonies* as well, unpacked on their arrival at Chiswick from China. I little thought at that time I should grow and flower

some of them in New Zealand as well, on property held in my own perpetual right.

Many of the plants enumerated may be considered by your readers old and stale; but I can assure you in a new country like this they are most lovely, and produce in my mind many, very many recollections of the past, some pleasant, and some painful, particularly those about "the reign of terror" to subordinates at Chiswick garden. I see by reading your Journal every mail those days are past; the Society seems now to have the right man in the right place in Lieut.-Col. Scott.

What I have written of my doings here is the result of immigration to New Zealand. I was sorry to read such bad accounts in the Journal about emigration to America. Emigrants to any colony must not be afraid of hard work. I say to them, Persevere, and you will conquer in the end as I have done. I work very hard at the present time with the spade; my hands are calloused, which is a pleasure to me when I look at them, and know that myself, wife, and family are to reap the benefit, which I consider much better than toiling in a gentleman's or nobleman's situation at home. Independence is sweet in any country. People say first impressions of any place are generally lasting. Mine were of this place these; "There's a living to be got here for my wife and family if I persevere and work hard." This proved quite correct in my case. I have been, and am being rewarded for my perseverance and industry.

Having worked very hard for what I possess, I have learnt a lesson as a working man how to take care of it. Living at ease here for a working man is quite out of the question at the present day. I have seen many instances here of working men getting into the lawyer's clutches in the shape of borrowing money on their homesteads, &c.; their troubles then generally begin.

Bees very busy to-day, carrying pollen for the first time. I can perceive to-day that winter crops of vegetables are just beginning to "cheer up." Cabbages and Coleworts, Broccoli, and Winter Spinach are all on the move after a long winter's rest. The weather during the present and past winter has been the most severe I have known in Canterbury. Our census states Canterbury has 2,800 acres in orchard or gardens.—WILLIAM SWALE, *Aconside Botanic Garden, Christchurch, Canterbury, New Zealand.*

A NEW ROSE.

MADAME ALICE DUKER, which I before said was a promising Rose, is now (September 30th), blooming a second time. It is worthy of adoption. Its present bloom is coloured at the edges of the petals like Louise Perle. I see, by Mr. Turner's list just arrived, that it won a gold medal. It is thus described, "Bright rosy pink, very large, full, globular form; superb. Gold medal, Orleans, 1866." The description is just.—W. F. RADCLYFFE.

ESCALLONIA MACRANTHA.

In the pleasure grounds here there are several plants of the various kinds of *Escallonia*. Of these *Escallonia macrantha* has grown very freely. There are some plants of it in a clump surrounded by grass, and almost directly in the way of persons crossing from one side of the grounds to the other, and I do not remember noticing in former years any unpleasant odour from the plants; but ever since those welcome and refreshing rains which fell in the middle of August, I found, on passing the clump, that it emitted a very unusual and rather unpleasant smell. It is observed most in a calm dewy morning, when the air is still. I will not positively say that it is given off by the *Escallonia*, but the only occupants of the bed besides it are a few well-known plants from which I have never noticed any such odour. They consist of a few plants of *Lycasteria formosa* and *Fuchsia Riccartii*, surrounded by a band of *Perilla nankinensis*, with a broad band of *Verbenas* all round, in panels and contrasting colours.

From which of the plants does this singular smell proceed? I know of nothing which it resembles so much as that of a heap of crushed or ground bones, such as farmers mix up with some carthy material before putting it upon their land. To-day, the air being damp and calm, while I was passing in front of another border, I detected a similar smell, and looking amongst the shrubs I saw a plant of the *Escallonia* growing there, which still more induced me to think that the smell must proceed from the *Escallonias*. I write not so much with the view of affirming such to be the case as to inquire if any of

your readers have observed an offensive odour where Escalloniae are growing. When I drew them slightly through my hand I could not detect it. Does it only accumulate sufficiently to be perceptible to the senses when the air is damp and calm, and in a sheltered position where it remains almost stagnant close to the earth? The plants here occupy a sheltered position, where dews remain almost undisturbed in very calm weather.

I shall be glad to learn if anything similar has been observed by others. From what part of the plant can the odour be emitted? Does it proceed from the flowers?—G. Dawson.

ROYAL HORTICULTURAL SOCIETY.

OCTOBER 6TH.

FRUIT COMMITTEE.—G. F. Wilson, Esq., F.R.S., in the chair. Messrs. Stuart & Mein, of Kelso, sent two plants of Curled Parsley, which the Committee did not consider any improvement on the existing variety in general cultivation. They also sent a Celery for garnishing, which the Committee considered too coarse for that purpose. Mr. Todman, of Aldershot, sent a basket of thirty-two Onions, weighing in the aggregate 35 lbs. They were remarkably fine specimens. Mr. Todman intimated that these were obtained by him by crossing the White Spanish with the Tripoli, and he named the variety Ne Plus Ultra; but in the opinion of the Committee it did not differ from the White Spanish. Among them there were some specimens of the Yellow Onion of Holland. The Committee commended the exhibition on account of the culture, but not as a new variety. Mr. Colbourn, gardener to J. Blyth, Esq., Woolhampton, Berks, sent very fine specimens of Salway Peach, which were so much admired by the Committee that they awarded it a special certificate. Mr. G. Ward, gardener to T. N. Miller, Esq., Bishop Stortford, sent a splendid fruit of Smooth Cayenne Pine, weighing 10 lbs., to which the Committee awarded a special certificate. Messrs. J. & E. Small, of Colnbrook, sent a dish of fine large Walnuts, which were excellent in flavour. Mr. DREWETT, gardener to Mrs. Cubitt, The Denbies, sent specimens of Meredith's Scarlet-flesh and Willis's Green Gem Melons, but it was evidently too late for Melons, as the flavour was indifferent, and it was remarked that Meredith's Scarlet-flesh was the same as Turner's Gem. A new hybrid Melon came from Mr. Rideont, gardener to W. S. Brown, Esq., Reigate, but the same observation is applicable to this as to the others.

Mr. Beach, Kingswood Warren, Epsom, sent fruit of a Green-fleshed Melon, very sweet, but with no flavour. Mr. Stewart, of Nuneham Park, sent a fine large fruit of Dr. Hogg, but the flavour was inferior. All of these Melons had evident good qualities, but the late period of the season is against the production of flavour.

Messrs. James Veitch & Sons exhibited a seedling dessert Apple, called Cloke's Seedling, raised at Cheltenham. It is of a roundish ovate shape, even and regular in its outline, of a rich yellow colour on the shaded side, and streaked and mottled with crimson. The eye is small and open, with segments reflexed at the tips, and placed in an even saucer-like basin. Stalk half an inch long. Flesh very tender, very juicy, sweet, and with a fine flavour. It was awarded a first-class certificate. Messrs. Small, of Colnbrook, sent a large Apple, strongly resembling Golden Noble, large and handsome, and of good flavour. It was named Queen Victoria, but the Committee were of opinion that it was not sufficiently distinct from Golden Noble. Messrs. Harrison, of Leicester, sent a fine large seedling Apple, with a brisk, crisp flesh, called Annie Elizabeth, which received a first-class certificate as a kitchen Apple. Mr. Sampson, of Yeovil, sent a large seedling kitchen Apple, called Benediktine, of pale colour, and a fine brisk acidity. It was said to keep till January, and Mr. Sampson was requested to send it again in January. Mr. W. Plester, gardener, Elsenham Hall, Bishop's Stortford, sent a seedling dessert Apple from the old Summer Golden Pippin, but it had no merit to recommend it.

Mr. Stewart, of Nuneham, sent a splendid dish of Seckle Pears. They were beautiful in appearance and delicious in flavour. Mr. Whiting, of The Deepdene, produced fruit of Gansel's Seckle, to be tasted in contrast with Seckle. This is a fine Pear, and has not so much musk in its flavour as Seckle. Mr. Whiting also sent Beurré Superfin, which this season is rather acid and bitter. Althorp Crasanne was dry and mealy, Marie Louise from a wall was very delicately flavoured and rich, and those from a pyramid were more russetty and with a stronger and more pronounced flavour. Kingessing is a large and handsome American Pear, but the flavour was not good. A special certificate was awarded to Mr. Whiting for this collection.

Mr. Rideont, gardener to W. S. Brown, Esq., Reigate, sent fruit of Granddilla, and jam made from it. The jam was rather sweet, but on the whole was approved by the Committee. The Committee awarded a special certificate. Mr. Wells sent some excellent examples of Vines, laden with fruit, grown in ground vineries.

Mr. Charles Lee, of the Vineyard, Hammersmith, sent a bunch of Black Hamburgh Grape, perfectly ripened against his house.

Mr. Robert Collins, gardener to Major Trevor Clarke, sent a very nice collection of dessert Apples, which received a special certificate. The Rev. Lister Lister, Monkton, Charnworth, likewise contributed a collection of Apples and Pears grown in his district.

FLORAL COMMITTEE.—Several collections of plants made this meeting very attractive, and the additional interest caused by the competition of the edible and poisonous Fungi brought a goodly attendance of Fellows. The awards made by the Committee were as follows:—Mr. R. J. Gray, of Newlands, Alphington, received a first-class certificate for *Polystichum angulare* Grayii, each frond being branched. Messrs. Veitch received first-class certificates for *Vanda insignis*, true. They exhibited two flowers of varieties that have been sent out as insignis, one buff, the other purplish white, differing in many respects from the true *Vanda insignis*; *Araucaria elegans*, a beautiful Conifer; and *Adiantum densum*, a very distinct Fern. A special certificate was awarded for their collection of Orchids, also for their miscellaneous collection of plants.

Mr. B. Williams, Holloway, sent *Cattleya maxima superba*, *Mil-tonia Moreliana*, and *Odontoglossum hiconense splendens*. A special certificate was awarded for his collection of plants. Mr. Warren, Salisbury, sent a collection of seedling Zonal Pelargoniums. A hybrid Begonia raised by Major Trevor Clarke, *B. weltonensis*, was awarded a first-class certificate. The plant was covered with bright rose-coloured flowers, and has been in bloom since April. This variety is in the hands of Mr. A. Henderson, who exhibited it in February, 1864, as *B. ornata*, when it received a second-class certificate. The specimens exhibited were grown at Chiswick. A beautiful seedling Coleus came from Chiswick gardens, and received a first-class certificate. It was named Queen Victoria. This is a very distinct and beautiful variety, the leaf having a dark maroon centre with a bright golden margin. Many other seedlings were sent, which are to be examined again. Several handsome yellow-leaved Caladins came from the gardens, and a beautiful yellow-foliaged Fuchsia, very distinct and good. By some mischance this plant was not brought before the Committee.

Mr. Coomber, gardener to Col. Wilkinson, brought a silver-edged Zonal Pelargonium, having a bright red zone, and named Mrs. Col. Wilkinson. It was exhibited at the last September meeting, and received a second-class certificate; but it had improved so much that on the present occasion it was awarded a first-class certificate. Mr. Bull sent seedling Coleus Victor, a good variety, but too much like some others; *Coleus refulgens*, and *Coleus Masterpiece*; *Abies japonica*, an *Arceuthobium*, *Veronica Celestial*, *Cupressus Balfoaria*, *Phytolapha macrocarpa*, *Ptychosperma elegans*, requested to be seen again, and *Nothochlana candida*, a Fern exhibited in 1866 as *N. cretica*, and which received a first-class certificate in that year. Mr. Bull was awarded a first-class certificate for a beautiful *Anætochilus*—*Dawsonianus*, also for *Calamus Lavisianus*, a second-class certificate for *Gymnogramma Lachneana* var. Mr. Wright sent seedling Dahlias; Mr. Rawlings the same, and received a first-class certificate for Emperor, a fine dark purple flower. Mr. Bragge received a first-class certificate for seedling Dahlia Commodore, a bright buff flower. Mr. Groom, Ipswich, sent three seedling Zonal Pelargoniums—namely, John Hopper, light scarlet, Mrs. Sach, white, and Climax, salmon rose. These flowers were of some merit, but as exhibited not first-rate.

Mr. DREWETT, gardener to Mrs. Cubitt, Denbies, sent some flowers of a seedling pink *Tasconia*; and Mr. Chambers, Beddingham, a seedling *Lobelia alba*, white. Mr. Green, gardener to W. W. Saunders, Esq., Reigate, received a first-class certificate for an *Oncidium*. He also sent a new *Bulbigeria*, named *Saundersii*, from Bahia. Mr. Church, Plumstead, sent a seedling Zonal Pelargonium, hardly free of the guard leaf; and Mr. Ferguson, a variegated form of the common Minsk plant. An *Odontoglossum grande*, from the Society's garden, Kensington, with six flowers in great perfection, received a special certificate. Mr. Tanton, Epsom, again brought his *Allamanda Ward-leana*, which has been decidedly proved to be *A. Hendersoni*. Major Trevor Clarke brought four very beautiful varieties of the Autumnal Crocens, *C. byzantinus* or *nudiflorus*, *C. longiflorus*, *C. pyrenæus* or *nudiflorus*, and *C. speciosus*; the delicate shades of blue or grey were very beautiful. Major Clarke also brought a branch of the scarlet-fruited Egg Plant, which was very handsome; likewise another *Solanum*, producing scarlet fruit, the plant having very prickly foliage.

GENERAL MEETING.—J. Russell Reeves, Esq., F.R.S., in the chair. Four new Fellows were elected. In announcing the awards of the Floral Committee, the Rev. Joshua Dix directed attention to an Onion plant raised from one found in a plaster cast several years old, which had been broken up in the studio of Mr. Noble, the eminent sculptor, and suggested as the vitality of the Onion had been preserved so well in the plaster of Paris, the circumstance might afford a hint as to the preservation of other bulbs imported from abroad. G. F. Wilson, Esq., F.R.S., reported the awards of the Fruit Committee, and added that the first and second prizes, of the respective values of £3 3s. and £2 2s., given for edible Fungi by Lady Dorothy Nevill, and Mrs. Lloyd Wynne, had been awarded to Dr. Ball, of Hereford, and Mr. Worthington G. Smith, of North Grove West, Mildmay Park.

Major R. Trevor Clarke then expressed his regret that on an occasion when Fungi had been brought forward in number, that great mycologist the Rev. Mr. Berkeley, owing to an indisposition, had been unable to remain at the meeting, and make remarks on the Fungi exhibited. Fortunately, however, the two exhibitors who had gained the prizes, were also mycologists, and had consented to offer some observations on the subject; but before calling upon them to do so, he would direct attention to the four species of beautiful autumnal Crocens

which he himself had brought. These were the *C. pyramus* of Herbert, or *C. nudiflorus* of Hooker, which is naturalised in Lancashire, and also to be found in meadows in Warwickshire; *C. byzantium*, otherwise *C. iridiflorus*, an extremely beautiful *Crocus* which simulates the Flag or Iris, the corolla standing up, while the sepals fall downwards; *C. longiflorus*, and *C. speciosus*, also of very great beauty. These four *Crocuses* follow each other in succession, beginning to flower in September and ending in midwinter. They were published by Dean Herbert in his "Crocorum Synopsis," and the specimens exhibited were raised from seed given to him (Major Clarke) by the Dean's brother, Mr. Algernon Herbert. Major Clarke then pointed out a *Solanum* raised from seed sent home by Dr. Jamieson from the Peruvian Andes, and remarkable for the beauty of its orange fruit, which was used as an ornament for the hair by the ladies of the country.

Mr. Liggins said that the plant was a common weed in Montserrat, covering many acres of ground. There were two kinds, one of which had fruit three or four times the size of that on the plant exhibited, and when seen in the sunshine the effect was very striking. Another was known as the Prickly Apple.

Major Clarke remarked that there were many species of *Solanum* with ornamental fruit, and instance one with scarlet fruit, which had been raised from seed sent to him as that of the true Scarlet Egg Plant or Brinjal. *Begonia weltonensis*, noticed in our Floral Committee report, was then referred to, and Major Clarke said his reason for doing so was that the plant had been attributed to him, instead of which it was the property of Mr. Arthur Henderson, to whom he had given the seeds. At the close of his remarks, Major Clarke exhibited a flower raised from seeds sent to him as those of *Dahlia imperialis*, a miserable specimen of a common small-flowered *Dahlia*.

Dr. Bull, in rising to make some observations on the Fungi exhibited, said that he laboured under the great disadvantage that he had not expected to be called upon to undertake such a task. One of the main objects of his attending the meeting had been to hear Mr. Berkeley, therefore those who were present could not be more disappointed than he was himself at Mr. Berkeley's being under the necessity of going away. A prejudice existed with regard to Fungi, which caused difficulties in approaching the subject, but it was extraordinary, though the ground was teeming with food in the shape of Fungi, that these should be wasted. The first species to which he would direct attention was *Fistulina hepatica*, "the Vegetable Beefsteak." This, as stated on the label attached to it, is the best possible addition to a beefsteak, and a beefsteak in itself if properly cooked. If prepared by a good cook along with ordinary gravy, anyone would believe it to be a beefsteak. Another Fungus, very different in its character, was the Puffball, *Lycoperdon giganteum*, of which the Chairman exhibited specimens. Three weeks ago he had seen one 3½ feet in circumference, and weighing 6 lbs. Sliced and frittered, or in whatever way cooked, it acts as a vegetable egg. His belief was that all Puffballs in a young state are really edible, but their growth being so rapid, there is a corresponding rapidity of decay, and when that commences they are unwholesome, though they would not be so if taken young enough. Certainly some inconvenience from eating *Scleroderma vulgare* had been lately recorded, but the specimens, no doubt, were rather old. Although all Fungi were not fit for food, it would be a very unusual occurrence for him not to be able to go out in the autumn months and bring home some Fungus good to eat, though he did not mean to affirm that every one would be equal to the common Mushroom. Still there were some, *Agaricus procerus* (the Parasol *Agaric*), for instance, which he thought superior to the ordinary Mushroom; and in different species there was a considerable diversity of flavour. The Chairman had brought the finest specimen of *A. procerus* in the room, as far as size was concerned, but it would not be so for flavour, for when so large this *Agaric* was only fit for catsup. It should be small, and then it was lighter and more digestible than the ordinary Mushroom. It might be cooked in any way, and was excellent in all. It was distinguished by a loose ring and the snake scales on the stem. In the prize collections it was to be seen in all its characters. *A. (Lepiota) nancinus* next came under notice, and Dr. Bull related that he and some friends had partaken of it, and very much enjoyed it, thinking that it was *A. procerus*, but finding the flavour not quite that of *A. procerus*, they examined the specimens and found them to be *A. nancinus*, and this he stated to be a delicate *Agaric*, which may be cooked in all the ordinary ways. Next he came to the Maneel *Agaric*, *Coprinus comatus*, about which there could be no possible mistake. It might be found during four or five months in the year by the sides of byways, and in waste places; its abundance was extraordinary. As the label stated, it has a delicate flavour, and when boiled in the ordinary way and served on toast is thought by many connoisseurs equal to any *Agaric* grown. It requires to be eaten in a young state.

The Horse Mushroom, *Agaricus arvensis*, was next referred to, and Dr. Bull stated that, on passing through Covent Garden, for the one or two dishes of the common Mushroom (*A. campestris*), which he saw, there were dozens of the Horse Mushroom, which, however, was perfectly harmless, and might be cooked in every way like the common Mushroom, and by many was thought equally delicious. It requires, however, rather more time. The Fairy Ring Champignon, *Marasmius oreades* was also exceedingly good when cooked as follows:—Put the *Agarics* on toast; salt, pepper and butter (or add a little melted or

scented cream), put a clove on the toast, cover with a glass, and bake or broil before the fire for twenty minutes. Serve up without removing the cover. *Agaricus prunulus*, called by some Vegetable Sweetbread, which also grows in fairy rings, was called by Badham "the dainty Oreella." It was a delicate kind requiring light cooking. A friend of his (Dr. Bull's) said that every Fungus found growing in fairy rings was wholesome, but there were some which if so were not good.

Passing from edible to poisonous Fungi, Dr. Bull remarked that the proportion which the latter bear to the former is not greater than that of poisons to wholesome plants. Poisonous plants were known and avoided, and it was just that knowledge which was required with regard to Fungi. Just as people did not go and pick up every plant for use, so one ought not to gather the first Fungus he might meet with. The knowledge was easily acquired, and through the aid of Mr. Smith's excellent plates "fungophagy" was spreading very fast. Still he (Dr. Bull), thought the Royal Horticultural Society had done exceedingly well to encourage an exhibition of Fungi, for though figures and descriptions in books were very useful, they were not equal to the actual specimens.

Noticing a few more edible Fungi, Dr. Bull held up a specimen of the *Cantharellus cibarius*, the true Chanterelle, and said that if one gave an entertainment the French cook would ask for the Chanterelle, and guineas would probably have to be paid for that which should only cost shillings, as the Chanterelle grows abundantly near London. As stated on the label, it is excellent in every way. By itself, sliced and stewed with butter, pepper, and salt, it makes an excellent dish with a Mushroom flavour. An allied Fungus bearing considerable resemblance to the preceding, was then exhibited; but though it might be mistaken for the Chanterelle, no harm, it was said, would result.

Several poisonous Fungi were then briefly noticed, and among them *Boletus luridus*. The next was one startling for its beauty—namely, *Agaricus muscarius*, than which Dr. Bull said he did not know anything more beautiful in nature, especially the specimens sent by Mr. Reeves. It was one of the most poisonous Fungi known. Dr. Badham had sent it to some ladies to be sketched, intending to call on them and speak to them about it, but was prevented from carrying out his intention by an urgent case. The ladies, thinking that what came from Dr. Badham was sure to be good, after sketching it had it cooked, partook of it, and when Dr. Badham came they had been carried to bed intoxicated by its action. In fact, this *Agaric* was used in Russia for the purpose of producing intoxication. If cooked at all, however, it lost a portion of its poison. In connection with this fact, he would mention that there was once a doctor in Paris who undertook to eat any Fungi brought to him, but before cooking them they were soaked in vinegar and water, and he then ate them with impunity. Other poisonous species were *A. fascicularis*, which is commonly met with; *A. sulphureus*, rare; *A. squarrosus* extremely beautiful; and three very interesting Fungi were *Cyathus vermicosus*, *C. striatus*, and *Sphaerobolus stellatus*. Among species gay in colour, there were the scarlet *Peziza* and *Russula rubra*. *Bulgaria inquinans*, which is found on the bark of trees, was also exhibited to the meeting.

Dr. Bull concluded a long and very interesting discourse by observing that unless the educated classes could be induced to eat Fungi, the poor would never be brought to do so. In his own neighbourhood the Field Naturalists' Society had taken up the subject, in consequence of the action taken by the Royal Horticultural Society. Example was better than precept.

Mr. W. G. Smith said he would make a few remarks on the seeds or spores of Fungi, as Dr. Bull had not touched on that subject. Nearly all the Fungi with white seeds were edible, and in form such seeds were generally roundish, or roundish oval, whilst the poisonous Fungi generally assumed forms of angular outline, and one of those exhibited had spores which seemed as if covered all over with spikes. The colour of the seeds of Mushrooms was generally that of the gills, and all pink seeds generally were angular in their form. With regard to *Agaricus muscarius*, he would add that he had never found it anywhere but under Birch trees.

Mr. Blekins moved a vote of thanks to Dr. Bull and Mr. Smith, which was seconded by Major Trevor Clarke, the latter remarking that the meeting had been one of the most interesting *soirées* at which he had been present. The motion having been unanimously carried, Major Clarke called attention to a process by which the curious frail *Agarics* are preserved in the greatest possible perfection, and which it was stated was devised by Mr. English, of Epping, who exhibited examples of several species.

In addition to the species of Fungi noticed above Dr. Bull had *Hydnum repandum*, of which Mr. Berkeley has stated that there is not a more excellent Fungus when steeped in hot water, drained in a cloth, and cooked in the ordinary way; *Lactarius deliciosus*, the Orange Milk *Agaric*, stated by Badham to be tender as lambs' kidneys, and for cooking which Soyer has given directions; *Agaricus rachodes*; *Gomphidius viscidus*, a mucilaginous species; and *Agaricus melleus*, which should be steeped in vinegar and water for half an hour, then peeled, and fried with butter, pepper, and salt, with the addition of a little Hervey sauce and a clove or two.

Mr. Smith's collection comprised a large number of species, both edible and poisonous; and J. C. Reeves, Esq., Hantsland, Worth, Sussex, and J. R. Reeves, Esq., sent several fine specimens, some of which have been referred to above.

HORTICULTURE IN THE HOSPITAL—A HAPPY THOUGHT.

IN the report of the proceedings of the meeting of the governors of the Hospital of Incurables, we find chronicled what appears to us to be a charming gardening episode, and a beautiful illustration of the sympathies and kind-heartedness of a noble lady, the members of whose house have ever been amongst horticulture's foremost and most distinguished patrons. We are told that on the occasion a letter was read from Mr. G. Smith, head gardener at the Viceregal Lodge, saying that he had forwarded a number of plants which he had been directed specially to prepare for the institution by her Grace the Duchess of Abercorn. Her Grace was not mistaken in the gift. Gardening ministers largely, indeed, to our material and everyday wants, as well as to the elegance and luxuries of life; but it is yet more blessed in its resources for relieving the tedium and *ennui* of the sick-room, or, mayhap, giving a fillip to the sinking frame, which has often been the turning point to recovery. There are few physicians who are not familiar with instances where a bunch of forced Grapes or delicate vegetable strengthened their hands when hope was almost gone, and was found more potent for good than all the medicines in the Pharmacopœia. So, too, in the room of the confirmed invalid, a Fern stand or a few pot plants become as friends, and a recently gathered flower is a joy which brightens up, albeit though only for a moment, the lustreless eye of hopeless suffering.

It has been truly said that the love of plants and flowers is—

"An ingredient in the compound man,
Infused at the creation of the kind."

In truth it was a kindly, and a thoughtful as kindly, act, when her Grace instructed Mr. Smith to prepare these specimens to present to the incurables. The institution has more than once been visited by her Grace, and we have heard a distinguished physician, who takes an especial interest in it, frequently speak with enthusiasm of the Duchess's prolonged visits, and the time she spent by the bedsides of the patients. —(*Irish Farmer's Gazette*.)

PEAS.

DICKSON'S FIRST AND BEST.—I consider this Pea a most valuable kind. I have at present a splendid crop from seed saved from the first sowing literally covered with pods and flowers. Not so with some other early kinds sown at the same time, and afforded the same treatment.

THE PRINCE (Stuart & Mein), is another valuable kind to which I wish to call attention. It was sown with some other old and well-tried kinds in spring, but was much superior in every way, branching out from the axil of every leaf, and bearing most profusely. This, in my opinion, is distinct from all the other dwarf Marrow varieties. —E. WELSH, *Palace Gardens, Armagh, Ireland*.

NOTES AND GLEANINGS.

ON the 29th of September died Mr. HENRY BAILEY, one of the best of our English horticulturists. He had been head gardener to Earl Spencer, at Althorp, and to the late Mr. George Harcourt, at Nuneham. When the gentleman last-named died, he bequeathed Mr. Bailey an annuity of £100 for life, and this induced him to retire from garden service. He resided at Amersham, and was in his 65th year at the time of his death.

PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

PUYA WHYTEI (Whyte's Chilean Puya). *Nat. ord.*, Bromeliaceæ. *Linn.*, Hexandria Monogynia.—"A superb rock-plant," introduced by Messrs. Veitch, from Chili. Flowers dull blue.—(*Bot. Mag.*, t. 5732.)

LINARIA ORIGINIFOLIA var. CRASSIFOLIA (Thick-leaved-Marrow-leaved Toad Flax). *Nat. ord.*, Scrophulariaceæ. *Linn.*, Didynamia Angiospermia.—A hardy rock plant. Native of South of France, Spain, and Portugal. Flowers purple and lilac.—(*Ibid.*, t. 5733.)

BLANDFORDIA CUNNINGHAMII (Allan Cunningham's Blandfordia). *Nat. ord.*, Liliaceæ. *Linn.*, Hexandria Monogynia.—Native of the Blue Mountains, New South Wales. Introduced

by Messrs. E. G. Henderson & Sons, Wellington Nurseries. Flowers orange scarlet, tipped with yellow outside; inside all yellow.—(*Ibid.*, t. 5734.)

ARECA BAURI (Bauer's, or Norfolk Island Betel Palm). *Nat. ord.*, Palmæ. *Linn.*, Monocia Hexandria.—This Norfolk Island Palm flowers annually freely in the Kew Palm House, and less well in the temperate houses.—(*Ibid.*, t. 5735.)

ODONTOGLOSSUM CONSTRICTUM (Narrow-petalled Odontoglossum). *Nat. ord.*, Orchidaceæ. *Linn.*, Gynandria Monandria.—It is a native of Caraccas. Flowers yellow, blotched with brown.—(*Ibid.*, t. 5736.)

GOLDEN CHAMPION GRAPE.—"It is not only a decided novelty, but a novelty of the very highest excellence. Free and robust in growth, hardy and prolific in habit, magnificent both in berry and in cluster, and exquisite in flavour, what more can be desired? In truth, its merits are of so high an order, that they leave little to be wished for.

"The bunch of the Golden Champion is moderately large, compactly-shouldered, and somewhat tapered, with a stout fleshy stalk. The berries are very large, with stout warted footstalks, some 2 inches long, and 3½ inches in circumference; they are generally of an ovate shape, but occasionally somewhat roundish, and they have a thin, pale yellowish green skin, which acquires a rich golden amber tinge with a slight bloom when they are fully ripe. The flesh is tolerably firm, but tender, with few seeds, very rich and juicy, with a flavour which, though compared with that of the Black Hamburg, is, to our taste, much more saccharine and luscious than that variety, even when grown on the same stock.

"This new Grape supplies, so far as can at present be judged of it, a long-felt desideratum—namely, a high-class free-growing white Grape, of hardy constitution, suitable for general cultivation as a companion to that best of all Grapes for general purposes, the Black Hamburg. It was raised by Mr. W. Thomson, of Dalkeith, some five years since, from a seed taken from a Grape that was itself a cross between the Champion Hamburg and the Bowood Muscat, and has been freely exhibited during the present year, when, among other awards, it has received a first-class certificate from the Fruit Committee at South Kensington. The foliage is very slightly lobed, and deeply and sharply serrated."—(*Florist and Pomologist*, n.s., i. 217.)

MASTERS' TROUBLES.

"WELL! I do not know what to say about this new gardener. I am afraid he will not do. I do not care for half-work; if a man digs I like him to do it well, send his spade deep in as far as it can go, and put the top soil to the bottom, and bring up the dark, heavy, long-hidden lumps of mould with all their grubs and centipedes to the surface. A man knowing what he is about gives these lumps a blow with the spade, so that the fresh air may pulverise it, and the ever-busy birds begin their share of the labour." So grumbled Squire Butler as he sat under the shade of an old Thorn tree one warm morning in September.

"I think you are too particular," replied his wife, pausing in her occupation of cutting away the dead Asters; "he appears to be working hard whenever I chance to see him."

"Yes, I dare say, trying to catch the lost hours; yet I do not mean to say that the man is idle, but he is not skilful, he gives two knocks to a nail when one would do, and he might just as well have the strength and time employed for the second knock in doing something else. I obtain my money to pay this man by hard work, and I feel rather sore about so spending it, unless I get back something like value for value."

"Then, Frank, I am afraid your feelings will always be wounded, for gardeners never do return a money equivalent; you have plenty of beautiful flowers."

"But my wife cannot boil these for Cabbages, or turn them into Cucumbers, so it does not alter the case, or cause me to put faith in a man who cannot bend his back, and whose shoes are so bright that he can see his face in them, and who must blow away the dust from a stone wall before he can put down his jacket."

"Well, I admired the man, he was so clean and tidy."

"Yes, even to his hands. He is too much so for me. What would you say to your cook if she sent up your Potatoes unscrapped on the score they dirtied her fingers? And a gardener may be too clean to be worth much."

"You must acknowledge, at least, that he is very respectful."

"I dare say he is, Clara. You women are always taken by that, plenty of touching his cap, and 'Good morning, Ma'am.'

I am afraid he pays all his respect away, and is earning none for himself. And then, too, his heart is not in his work, and I never yet met with a man who succeeded well in doing things he did not like. Did you ever notice with what a slow, uncaring-what-time-he-gets-here walk, he comes in a morning, and the joyful, springing, telegraph speed with which he takes his departure in the evening? I assure you a workman does not care much for his employment when he is over-anxious to leave it—when he is all day counting the minutes until it shall cease, and relief come. And during the last half hour this new man of ours must have been at least half a dozen times to look at the stable clock. I suppose he has a wife at home, a harder master than the one he has here, so he is dreadfully uneasy lest he should be late. I should not wonder if he has not all his tools put away, everything ready for leaving a minute before the time, even the key turned in the lock."

"What is the matter? Frank, you do not know what it is to work all day in a garden, or you could understand why a man should be ready to go home at night. And if they have rules laid down, so many hours for so much, I do not see you have any right to expect they should stay longer."

"Certainly not, nor should they stay less. So many hours' labour for so many shillings. But what for the lost five minutes here and there, the idle chattering with pretty housemaids at kitchen doors, the packing-up of vegetables for home consumption? All this unnecessarily, I think, in the paid-for time. So much a-month for service not rendered. In my father's time a man worked two hours longer for 3s. than he does now for 4s.; but then a garden was thought a luxury, now we call it a necessity. Why the fact is, it is becoming every year more and more of a luxury. This little place costs us 8s. a-week and four glasses of ale—a large slice out of our weekly pudding. I begin to think it is beyond our means. This sum would go a long way in the purchase of flowers and fruit. I would not care if we could meet with a gardener with a bit of conscience about him, one who could look at both sides of the question, and ask himself now and then how he would like to pay a man wages for doing an indifferent amount of work in an indifferent manner."

"We have had ill-luck with our gardeners, Frank, but others may have met with men more suited to their requirements."

"Then they have been favoured; yet I know scores of masters who feel just the same as I do, and yet they cannot, or dare not speak out. They are afraid of the very men they employ, or, at least, they are afraid that the gardener should all at once take his departure, and they be left in a fix, the fires go out, the fruit spoil, and everything be wrong. So they put up with little evils, not seeing the end in the beginning, and, perhaps, hoping that everything will come right at last."

"Then," replied Mrs. Butler, "I think masters are greatly to blame; they should speak out fully and clearly what they mean. If it is too much trouble to do so, or they are afraid, no wonder affairs go wrong. I suppose if a gardener left as early as he could after being spoken to, and you know he could not without notice, it would be quite possible to get another."

"Yes, but clever gardeners are scarce. I often think that half the men who set up for that trade know little about their work; they are like Sedgely, who when a lady asked him in what sort of soil she must repot her *Vallota purpurea*, replied, 'Oh! give it a bit of every kind you have. I always do.' There are plenty of men who can plant Cabbages, and earth-up Potatoes, but few you could wisely send to give water in your conservatory, or work in your flower garden. Our neighbour Grant was ill last winter; he does his own gardening, it is pleasure to do so. His wife, fearing it would grieve him to see the untidy state of his borders, engaged a man to do up the place. Not knowing where to apply to she walked through the village, and chose one who had a large sign over the door—So-and-so 'Landscape Gardener, jobbing work promptly attended to.' When poor Grant was able to go about again in April, and looked round his garden, he found his *Rosea*, for which he had paid no small sum, cut down within a few inches of the soil; bud and graft had been nothing to the landscape gardener. I suppose he never heard of such a thing, at any rate Grant has no *Roses* to send up to the church this thanksgiving season."

"I wonder Mrs. Grant did not look after him, seeing he was a strange man."

"She would consider that he knew what he was doing. And you know our Peas came up in a strange manner, long dead blanks in the rows, then small patches with the Peas crushing and crowding each other. I counted forty-seven in one patch that Nelly's cap would cover. And your brother Wilson

assures me that he has this season paid £9 17s. 6d. to a man for attending to a vegetable garden he had the folly to rent last autumn, and all its yield has been a few Radishes, one dish of dark green tough Lettuce, one dish of Peas not worth much, for they dropped upon the plate like pellets; a few Cauliflowers, among whose snowy arches the *Lepidoptera* had lodged ample surety that its species should not soon become extinct; and Potatoes, rather under than over the size of a walnut. He thinks the market the best garden; not without cause."

"But did he say how many Vegetable Marrows they had?"

"He never eata Vegetable Marrows."

"But his wife and children do, and he would be wise to cultivate a taste for them, they are as wholesome as any vegetable grown, and not costly, at least to the grower."

"I greatly dislike them, never could eat them."

"As a rule, gentlemen do. I think it is because they are so easy to prepare, and almost any gardener may manage to grow them."

"We never had a man who could or would grow them, or if he did he found a better market than his master's table. That reminds me of something which took place before I was married. Coming home late, or rather early in the morning, I met a man striding through the wood with a basket on his arm. Fancying it might be game, I stopped the man roughly, and would know what his basket contained. 'Only Strawberries, Master,' was his quiet reply, as though he had guessed my thoughts. And then he lifted up the cover, and some folds of soft white paper, and displayed the tempting fruit. Dear me! how fragrant it was, and how beautiful its appearance in the white moonlight of that cold March morning. 'Are they for sale?' I asked. 'No, they are sold.' 'All right, my good fellow,' I said, and hurried on home. Before going to bed I took the keys of the houses and went round. My father was very proud of his Vines, the earliest and latest and best of Grapes were ever to be found on his table—at least, he spared no expense to gain this end, it was his hobby; he was very fond, too, of forced Strawberries. I climbed the ladder and flashed the light of the lamp upon the long shelf in the forcing house on which the Strawberry-pots stood, no need to do it twice, the best and ripest were gone."

"What did you do, Frank?"

"Put away the ladder, locked all up, and held my peace, as they say. But that is not all. Next morning my father told me he was greatly disappointed our Strawberries were not ripe, as it was his birthday, but he had just received some from Walker, a fruiterer in the market. A little bill of £5 came along with the fruit. There was not a doubt they were my father's Strawberries I had met walking through the wood to come back again next morning. So he bought his own over again at a dear rate, as many a master may do, and know it not, for I cannot fancy this an isolated case."

"I should hope it is, or nearly so. Is your list of grievances at an end? I shall despair of ever meeting with a gardener to your satisfaction."

"Get one who knows his work, and can do it, and be proud of it. One who is not always blaming the seasons for every failure, who begins his work as a pleasant duty, and would rather stay half an hour longer than allow his own credit or his master's interest to suffer. I am sure his own interest would be secured by so doing. No one willingly parts with a gardener who reaches even half way up to the requirements of his position."

"Then we will try ours a little longer, as he more than half meets our desires."

I will next detail "Gardeners' Troubles."—MAUD.

GESNERA EXONIENSIS.

You could not have said better respecting the *Gesnera* than you have done, except your mentioning that the foliage is dark green; it really is brilliant plush. We send you by this post a leaf, as the drawing on which your notice was founded is calculated to mislead in that respect. In it neither the flowers nor foliage, as represented, are anything like so brilliant as the plants, which are now really splendid. They fairly light up the whole of our conservatory, and every visitor that calls pauses to admire them, and not one person out of a hundred that see it, and having the means to grow this *Gesnera*, but orders the plant.—LUCOMBE, PINCE, & CO.

[Messrs. Lucombe, Pince, & Co. do not exaggerate in their

statement relative to the foliage of this *Gesnera*. The leaf they sent is most beautiful, and seems formed of thick crimson purple Genoa velvet.—Eus.]

PHYTOLACCA DECANDRA OUT OF DOORS.

A PLANT of *Phytolacca decandra* has grown here (Usk, Monmouthshire), unsheltered, for several years. It regularly bears its grape-like spikes, has luxuriant foliage, and attains a height of 7 or 8 feet. Having lost one plant through the heavy rains of winter causing it to rot, a little long litter was last year placed over the crown when the stems died. The *Phytolacca* is admired by all who see it. A plant sent to a friend at Hampstead, has done well there. It has survived two winters.—H. W. E.

PEACH CULTIVATION.—No. 3.

TRAINING.—The best method of training the Peach tree is in the fan form, but it requires care and knowledge, for without these all the vigour of the tree will be expended on the upper part, and the bottom will necessarily be weak. The growth, too, is often very irregular from the branches being badly disposed, and the means taken to promote an equal distribution of the sap; but notwithstanding these disadvantages, I consider fan-training by far the best—indeed, the only eligible mode of training Peach trees against walls. Seymour's mode of training is by some preferred. I shall, therefore, treat of both methods.

Fan-training.—Having a maiden plant with a single shoot, it should be cut to two buds, as close to each other as possible, but not nearer the ground than 9 inches, nor farther from it than 10 inches. The buds ought not to be on the front or at the back of the shoot, but on opposite sides. This pruning ought not to be performed later than February, and not when the shoot is frozen. Any buds below the point of heading-over need not be rubbed off until the two buds have pushed shoots a few inches long; then remove all buds and shoots except the two referred to.

The shoots, as they grow, should be brought down nearly to a horizontal position, but with a slight incline upwards to a length of 12 inches, and then taken in a curve upwards, in

Fig. 1.

order to encourage growth as much as possible, so that by the end of summer the tree will have two vigorous shoots, as shown in *fig. 1*. *a, b*. In autumn, or by February, these should be cut back if strong to one-third of their length, if moderately vigorous to one-half, and if weak to two-thirds of their length. Bring them down nearer the horizontal line, but let the extremities still curve upwards, as shown by the dots *c, d*, *fig. 1*.

In spring a number of shoots will push from the shoots (or branches we must now term them), *c, d*. Four of these are to be retained as principal shoots—namely, one from the end of each of the branches, *c, d*, and one on each of those branches, as shown by the dotted lines, *e, f*, springing from the base of the branches *c, d*. On the upper part of the branches *c, d*, at every 9 inches a shoot is to be left, and not shortened until it has grown 10 inches, then take out the points of such shoots, but all others are to have the point pinched out at the second leaf if they grow more than 1 inch; but if they only produce a bunch of closely set leaves, leave them entire. If any laterals appear on the shoots on the branches *c, d*, stop them at the first joint, and this repeatedly throughout the season.

The intermediate shoots, stopped in the first instance at the second joint, must, if they again push, have their points pinched out when they have grown one joint beyond the point where they were stopped, and afterwards keep them closely pinched-in to one joint or leaf.

In autumn the tree will have the appearance of *fig. 2*, *g, g*, being the shoots left at 9 inches distance on the branches *c, d*, *fig. 1*; and on the under side of the branches, also between the shoots on the upper surface, there will be short stubby shoots, caused either by stopping or naturally produced, both calculated to afford fruit the following season. The disposition of the principal shoots is shown by *h, h*, and *i, i*, *fig. 2*; the lowest, *h, h*, being trained with their points curving upwards, so as to cause a more vigorous growth than if they were trained horizontally. The shoots *i, i*, ought to be trained straight, and if they grow more vigorously than the shoots *h, h*, either they must be depressed, or *h, h* be trained more upright, so that the latter may have, if anything, greater strength than *i, i*. The present year's growth must be shortened according to strength, one-third if strong, one-half if moderately vigorous, and two-thirds if weak. The bearing shoots, *g, g*, must not be pruned at all, unless the laterals on them are of greater length than 2 inches, then shorten them to the last joint, or that next the shoot; and the short stubby shoots between the shoots *g, g*, and

Fig. 2.

on the under side of the branches, are not to be pruned or shortened unless they are longer than 2 inches, then cut them back to the joint next the branch whence they arise.

The branches and shoots are, after pruning, to be trained as shown in *fig. 3*. The lowest branches are to be brought down to the horizontal line, so far along it as the bar and figure 2, which is at the end of the second cutting-back, and the shoot (now headed and a branch), above it ought to be exactly 1 foot from the lowest branch—that is, at the point where the figures 2 and 3 are situated. The distance from the stem of the tree to 2 should be 2 feet 6 inches, and the same length at 3. That may seem a great length to compass in two seasons, but with vigorous trees it often occurs. It is, however, immaterial whether this length be made in one or two years, if the branches originate at the proper place, and the bearing shoots along them at the proper distances apart.

In the third season shoots must be originated at all the points on the main branches, whence the dotted lines (*fig. 3*) proceed; but their treatment not differing from that of those of the preceding year, it is unnecessary to repeat it. I may, however, explain that the dotted lines show shoots originated the third season—namely, *j, j*, the third series of main branches; *k, k*,

Fig. 3.

the continuation of the second series; *l, l*, the continuation of the first series; and *m, m*, sub-branches on the first series of branches, there being 2 feet 6 inches from their origin to the stem, and 12 inches between the first and second series of branches where these sub-branches, *m, m*, are produced. The short dotted lines are the bearing wood.

The future years' training will be easily understood from

fig. 4. Every year two new branches are originated, and these may be termed principals; such are *n*, *o*, *p*, *q*, *r*, and upon or from these sub-branches are originated at every 2 feet 6 inches and trained straight so that there will be an interval of 1 foot

between the sub-branch and the principal branch at the point where the next sub-branch originates. Once formed, the principal and sub-branches are to be trained straight, which will be understood by fig. 4.

Fig. 4.

This mode of training is not in general practice, and for anything that I know to the contrary is original. It has for its object the furnishing of the lower part of the wall before the centre is filled with branches, to get the lower branches strong before the upper ones became strong, and the easily replacing

any branch when it has become worn out. No bearing wood is allowed on the under sides of the branches, except shoots kept closely pinched-in; and no disbudding is practised, as all shoots are pinched.—G. ABBEY.

WORK FOR THE WEEK.

KITCHEN GARDEN.

Broccoli, if your autumn sort and Cauliflowers come into use too fast, take up some and lay them in in the shade, where you can protect them with a mat or other covering if frost set in before they are required for use. After the first frost or so is over, there is not so much danger for some time about young or succulent plants. *Endive*, see that the wet or frost does not injure your plants. *Lettuce*, all the plants that are to stand the winter out of doors should now or very soon be in the ground. *Onions*, see also that the winter Onions are not eaten up by slugs or snails, and have some soot kept dry in one of the sheds to dust over young plants in or out of frames. *Spinach* should be thinned out a little more; the late rains made it fill up the rows more than usual. Pits for *Asparagus*, *Sea-kale*, and *Rhubarb* will now be in use where these vegetables are wanted early, but any dark place will do for the *Rhubarb* and *Sea-kale*, and this is generally considered the best way to force *Sea-kale* until after Christmas; the saving of dung and labour will meet the cost of rearing plants for that purpose, besides, the *Sea-kale* is so much sweeter and easier to manage in the dead of winter.

FRUIT GARDEN.

Every Pear tree that has thrown out strong breastwood for the last year or two, with plenty of blossoms and little fruit, may now or soon be carefully taken up, but on no account is the foundation of the border to be disturbed to trace down roots. If you cannot pull them up—a bad practice, however—cut them off at once and reduce one or two of the weakest, and the strongest branches of the head to correspond; train out the remaining roots at full length, and throw 6 or 9 inches of good earth over them, and if the trees look stunted next summer, water them well. Again, if your tree is a stunted, half-starved one, take it up also, and if the roots are sound give them fresh soil and reduce the head two-thirds, otherwise throw it away. You will judge for yourself of all the intermediate degrees, but let there be no wavering about the extreme points. All other fruit trees are to be dealt with after the same manner, and not only once in a lifetime, but as often as the symptoms appear. Then come the trenching and making of new borders. It is always a good plan to have a few young trees of all the best sorts of fruit in reserve ready to fill up vacancies. However promising a stock of trees may be, there is no saying how

soon failures may happen, and a few young trees will not take up much room, especially if you transplant every second or third year, and if they bear a few fruit so much the better, as you will then be sure what they are before you remove them to their final situations. Young Peach and Apricot trees should be thus nursed, before they are planted against the walls, after receiving them from the nurseryman, and this having been a good season for ripening the wood of fruit trees, no one who is not already provided should neglect the opportunity of buying in a few young trees to be nursed under his own care a year or two before they are wanted on the walls.

FLOWER GARDEN.

All showy beds near the windows, and half-hardy plants against walls, &c., ought to be protected from frost as long as possible. It is too soon as yet to disturb the flower garden by removing large shrubs, but high time to plant all the early Tulips, Narcissuses, and all such bulbs for flowering early next spring, also any herbaceous plants for the same purpose. Wall-flowers, double Rockets, Polyanthus, double Primroses, Hepaticas, and other spring-flowering plants that have been growing in nursery beds through the summer, may now be removed to their blooming quarters in the flower borders, and if surrounded with fresh compost they will repay the trouble in the spring. Auriculas should soon be put in their quarters for the winter. Nine-tenths of the collections grown in the country are wintered in glazed frames or sheltered by boards hinged to a wall; the great point, however, is to keep them from drenching rains when the plant is in a dormant state. Polyanthus may still be planted; the sooner the better. All offsets, seedlings, or unhealthy bulbs should now be in the ground, and as the main bed ought to be planted between the second week in October and the first week in November, everything must now be in readiness and the first favourable opportunity taken of putting them in the ground. In consequence of the late fine weather the beds ought to be in a good state for planting, and it would be a wise precaution to cover them with mats during the night, or on the appearance of rain, as it is advisable not to plant when the bed is too much saturated with moisture. Beds for Ranunculuses should now be prepared, and all compost heaps turned and sweetened. Vegetable refuse should be collected and put in heaps to decay. Draw-up the soil round the stems of Dahlias in a small hillock to prevent the

crowns of the roots being injured by frosts, which we may soon expect.

GREENHOUSE AND CONSERVATORY.

Let all greenhouse plants be cleaned, pots and all, before they are set on the new-cleaned shelves, and let the lights be down all day, and half down during the night, unless rain or frosts occur. If the Orange trees or any plants kept permanently in the conservatory have not been looked over of late, no time should now be lost in getting every leaf and pot as clean as may be, likewise the surface of the borders. As this house will now be kept more close, nothing inside can be too clean and sweet. *Beaumontia grandiflora* will grow freely in a well-managed conservatory, but will not flower without more heat at the roots, and as it is of the same natural order as the *Allamanda* and *Echites*, there is no reason why these should not be inarched on it as soon as it is long enough to reach near the top of the house. From this time till late in the spring some climbers in this house will require pruning and thinning-out, the whole of them will require a little dressing now and then, especially where they obstruct the light. One great advantage of climbers is, that most of them flower on the current year's growth like the Vine; all such ought to be very closely pruned at the final dressing.

STOVE.

From October to May the principal watering in the stove should be done before noon, and to the middle or end of January the house should be kept as dry as possible, a slight syringing, however, will be useful to keep the foliage free from dust, &c. A sunny morning is the best time to water overhead, and once in ten days will be often enough. All plants that require pruning or thinning-out before the next growing season, should be dressed at once to give more room for the rest. *Clerodendrons*, *Vincas*, and other fast-growing plants which require large pots in summer, should never be wintered in these large pots; turn them out and shake all the soil from the roots, and place them in as small pots as you can cram their roots into, but do not prune the roots much at this time. If the plants are free from insects, the walls whitewashed, and the flues or heating apparatus in good order, all may be considered in good condition to face the winter.

PITS AND FRAMES.

A multitude of greenhouse plants would do better in cold pits for the next two months than in the greenhouse. Even turf pits with boarded frames and asphalt coverings to put on in rainy or frosty weather, are far better for these sorts of plants as long as the thermometer shows no more than 6° or 7° of frost. All plants should be put in order for the winter as soon as possible; those that are well-established may be placed in their winter quarters at once, giving the most valuable ones the best places; but those not well rooted may be kept in heat a few weeks longer, for though theory may say, Keep them as quiet as possible, practice, which is a much better guide says, Keep them growing until they are thoroughly established, unless you wish to consign them prematurely to the rubbish heap.—W. KEANE.

DOINGS OF THE LAST WEEK.

NEARLY a week's rain has made us independent as respects water supply for a long time.

KITCHEN GARDEN.

Most of the crops have required no attention when let alone by intruders and vermin; and most of those planted during the summer and lately have grown very well. Where not a single patch of weeds could be seen a fortnight ago the ground is becoming green with them in their early stages; but a dry day and a scuffle with the Dutch hoe will soon put them out of sight again.

Celery.—During a dry afternoon earthed up a piece more Celery. As yet we have had neither a run nor bad head. Our only fear is, that we commenced using it rather early. The heavy rains have given a good soaking to the beds that had the heads merely cleaned and tied up. We are glad to see what Mr. Black says about sawdust for earthing up, as it confirms our own experience and observation. The hint about papering is good for early Celery where paper is plentiful, but merely tying the heads just lightly enough to let the heart rise and swell, will often blanch the centres of good-sized heads so as to render them fit for table. We have known Celery that was merely tied take a prize in September instead of that which had been earthed-up with great care, and where the judges did their

work so well, and the competition was so close, that they had to cut open every head. In a wet season when the ground was soaked, we once had fine blanched Celery in August by running slight straw bands round the plants, and of these we happened then to have plenty. Much good Celery is spoiled by over-earthing. Protection is needed in winter, and a little long litter is better than too much earth.

Potatoes.—We hear that there is a good breadth, and not late kinds, still in the ground. In districts where the drought was prevalent it was sound policy to take up the Potatoes before the heavy rains came, as these promoted at once a second growth. Many that are now sold from late taking-up are deceptive. We saw lately what seemed a good dish of Potatoes, but they were unfit for use, all their best properties having gone to a host of waxy progeny, and such only good to look at in the case of those who delight in a sound mealy Potato. Those which have remained long enough in the ground to produce a second crop, may be known by being harder and drier to the touch and look than sound unsprouted Potatoes. This matter was fully alluded to in July and August, and several now admit that it was their own fault that the bulk of their best-looking Potatoes are now uneatable.

Cucumbers.—As we have now plenty again in a heated pit, we have done away with those in frames, as we wanted the room for other purposes, and we could not have kept them on without a considerable waste of material in the shape of linings, &c. We are well aware that if we allow these young Cucumber plants to bear freely now, they will exhaust themselves by Christmas or before it. Unless where there is a proper Cucumber house, where fruit is wanted from Christmas and onwards, very little should be taken from the plants until the shortest day is past. In these dull days with rain falling heavily, a little fire heat, with air at top and bottom to give a gentle draught through, will harden the plants, and enable them to stand the sun better when it comes, as we may yet have fine sunny days in October.

Mushrooms.—Finished earthing up the last piece in the shed, and spawned one bed in the Mushroom house. Perhaps about one-third of these shallow beds consisted of droppings and two-thirds of straw and turfy loam. Such beds never become too close, but sometimes they become rather dry, so that though there is plenty of spawn in them, the Mushrooms do not come up freely enough. In such a case the best plan is to make holes with a pointed stick or iron at every 4 inches or so over the bed, and to water with dung water at about 140°, as that will not be too much for filling all the holes, and from them it will percolate through the dryish manure. Of two evils it is always better to have a bed rather dry than too wet. A few Mushrooms have appeared in the pastures of late, but after so much wet they are poor compared with those grown at home.

Mixed together grass and litter in a heap, as hot material, however rough, will soon be very useful in bringing on crops, and however rank the main body of the heap may be, it is always easy to secure the heat, and keep the rankness out of the atmosphere in which the plants are growing. In the wettest days a much-needed opportunity was given for cleaning sheds, whitewashing, scrubbing pots, making tallies, and preparing for potting freely, washing glass under cover, &c., as, after this season, we shall want nearly all the light the glass can give.

FRUIT DEPARTMENT.

Pruned and cleaned the first vinery, and in a few days will have it filled with flowering plants. As we have now only Plums left in our late orchard house, and as a few plants will do them no harm from watering, we have taken lots of *Primulas*, &c., into it, as being more safe than being out of doors, or even under frames. Covered with old sashes, and litter beneath them, the late vinery border, and this before the heavy rains came. The Grapes keep all the better when the roots are not over-wet. Put some litter over the earlier Vine borders, and would have covered them with glass, boards, or tarpaulin, to protect them from the rain, if we could. The litter would throw off much, and help to keep the autumn heat in. When we can do so, we prefer putting on a light layer of litter early, in preference to a mound of fermenting material later. In the last plan there may be, and often is danger. In the first there can be none.

Figs in our little Fig-house will not do much more good, except with such an amount of heat as we do not feel disposed to give them. Besides, when we have kept the plants bearing in the end of October, and a good portion of November, we always come off with a scantier first crop in spring than we liked.

Hardy Out-door Fruit.—In two dry sunny afternoons we gathered a good portion, as the winds were throwing down some of our best Apples and Pears, even from low trees, and all that fall run the risk of decaying, even before they are fully ripe. In such a season as this our cold clayey loam stands us in good stead. We have gently forwarded Ribston Pippin and Margil Apples, and Marie Louise, Louise Bonne of Jersey, and Beurré de Capiaumont Pears, and these seemed considerably in request; but the bulk of these and some later kinds we gathered the other day fresh and green, and the fruit, but for the blemishing in falling, would have been none the worse of a week or two more on the trees. Some of our neighbours have not had a Marie Louise Pear, and other fruits in proportion, left for weeks, all being naturally ripened and gone. We expect to hear that Apples and Pears on light sandy soils will be ripe much earlier than usual this season. We hear that in several places so circumstanced, even late fruit comes in much earlier than usual, so much so as to threaten a scarcity in winter and spring. Some soft kinds of Apples, as Codlins, Hawthornedens, &c., would not keep any length of time with us, but we see no signs, or at least not much, of such early maturity in the case of the late and hard kinds. Could we depend on sunny weather we would leave some a week or two longer, and would not have gathered so many, only the winds and heavy rains dashed some of the best to the ground; and though several, from falling on Strawberries, had a soft bed, it was grievous to see a bruise on huge Beurré Bosc Pears and on large Apples, which are much in demand for fritters, &c. In gathering, we left many for a day or two in hampers, to be placed thinly ere long, as the dry days seemed so uncertain and far between. We expected a fine day on the 3rd of October, but it scarcely ceased raining all day, and out-door work had to be left for in-door work. It would be interesting to know how the ripening of fruit has been affected by the singular summer. At one time we thought that our Apples and Pears would be very small, but after the first rains they swelled very much, and now many are rather above than below the usual average as respects size.

ORNAMENTAL DEPARTMENT.

Took every opportunity when dry of running the hand machine over the lawn, as the scythe, when it must be resorted to, takes up so much more time, not merely in the cutting but in the sweeping; for there is the cause of the delay. Rolled walks at all rough when wet, and even half-covered with water, as then there is no danger of the roller becoming claggy, and all rough stones are pressed out of sight. Some of our walks are rather smooth, and need no rolling, except to give them a shining surface at times. Salting now should never be resorted to where there is much traffic, as the gravel will remain moist so long afterwards. Where there are numerous weeds, and the walks are rough with pebbles, the salt will do no greater harm than cracking the pebbles and making them smaller. We often think that a somewhat rough-surfaced walk is a kind of luxury in winter, as, though not so pleasant to walk on as a smooth walk for those who have thin-soled boots and tender feet, there is no danger of the fine gravel sticking to the boots. The great evil of using salt late for smooth walks is that it will make them soft and adhesive in winter, when of all times they ought to be hard, and exhibit no footmarks.

For a week past there has been desolation in the flower beds, except those chiefly marked by their foliage, as Coleus, Iresine, Amaranthus, Golden Feverfew, Perilla, variegated Chrysanthemum, Cineraria maritima, Centaurea ragusina, and variegated Pelargoniums, all of which seemed the better of the rain. The flowers of other plants could not withstand the continued rains. There has, however, been such good growth, and even on Scarlet Pelargoniums such abundance of flower trusses, that if we had a few weeks of sunny weather we would have a second grand display in the flower garden. Such is our hope of this being the case, that we will break in upon none of our beds and borders by lifting until we see the signs of a frost that would injure the plants, and then a number of these can be taken up in a few hours, and placed under protection.

Pelargoniums that had been pruned-in and broken well afresh, we put in a shed under cover, to shelter them from the rain, until we have time to shake most of the earth from them, shorten roots if necessary, and repot in light sandy loam, in smaller pots, and add to the richness of the compost as we repot.

Cuttings.—Our chief work, as far as other matters would permit, has been making cuttings. Although we know it is late, we have put in many cuttings of the white-leaved Centaurea,

but then they are strong pieces, with good hard bottoms, and, therefore, not liable to go off. We shall take up a good portion of the old plants and repot, and from them obtain numbers of cuttings in spring, and these are always the best for forming fine outside edgings, whilst the older plants and cuttings struck in summer do best for the centre of the beds. This plant is valuable for forming contrasts with scarlet, purple, &c., and we should not like to be without it, but for artistic effect we do not consider it equal to the fine cut leaves of the Cineraria maritima, and that always looks better in a band, as round a circle, than in a straight line.

We recently detailed how we took off our Verbena cuttings late, and they could scarcely do better than they are doing in a cold pit. What we are taking off now, chiefly bedding Pelargoniums, are inserted thickly in pots, and placed in frames, where there is a little bottom heat, and a risk from rank steam besides. Our old gardeners when propagating under such circumstances, would have found the heat no benefit, as the damp would have taken off their cuttings wholesale. This is easily prevented by the knowledge of a little secret which we could not keep, but let out for the general benefit years ago, and that is, to give air, to prevent all accumulation of vapour, and yet prevent the cuttings unduly exhausting themselves by free evaporation. Our Verbenas, without heat, and put in late, have had air from 5 p.m. to 9 a.m., and then the air was cut off if the day was sunny, if dull and moist the air was left on. This is more necessary when bottom heat is given, as in the case of these late cuttings; and when such heat is not originally very sweet, though the materials are covered with what is sweet and more decayed. Shut up the cuttings under such circumstances night and day, and we shall expect to find damping and rotteness. Give fresh air all night, and in dull days shut down, or shade merely in bright sun, and you need not lose a single cutting. The close, confined, moist atmosphere is necessary to prevent the cutting exhausting itself, by transpiring its juices; but the confined atmosphere is the reverse of necessary, when the cutting would absorb rather than perspire, and from an ever-changing atmosphere it has access to fresh supplies of oxygen with which to excite and develop its vital powers. In looking at beds of cuttings we can generally tell whether they have had air at night or not.—R. F.

TRADE CATALOGUES RECEIVED.

Barr & Sugden, 12, King Street, Covent Garden, London, W.C.—*Autumnal Descriptive Catalogue of Bulbs and Plants.*

William Paul, Waltham Cross, London, N.—*Rose Catalogue, 1868-69.*

COVENT GARDEN MARKET.—OCTOBER 7.

The deliveries of home-grown produce have somewhat fallen off in consequence of the wet weather prevailing during the past week, and foreign goods are scarcely so plentiful at sales as they were, but prices have not advanced. Potato trade steady; first qualities at last week's quotation.

TO CORRESPONDENTS.

.. We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c.*, 171, Fleet Street, London, E.C.

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

ORANGEFIELD TOMATO (*G. Nunn*).—The berries you sent are not the Orangefield Tomato, nor anything like it, but are the Cherry-form of the Tomato. In foliage, shape and colour of fruit, the Orangefield much resembles the old Common Red in general cultivation; but is not so coarse-growing, and the fruit is not so large, nevertheless it is a very useful size. Mr. Record has gathered an average-sized fruit of the Orangefield, and weighed it against one of the Common Red; the former weighed $3\frac{1}{2}$ ozs., and the latter $5\frac{1}{2}$ ozs. The Orangefield tied to a stake in the open ground, and only $1\frac{1}{2}$ foot high, had fifteen other fruits fit to gather; the other, planted and trained against a wall, is 7 feet high. Mr. Record has gathered dozens of the common sort weighing $\frac{3}{4}$ of a lb. each.

JUSTICIA SPECIOSA (*M. H.*).—It is much mildewed. Dust the whole plant thoroughly with flowers of sulphur, after remaining on two or three days syringe the plant. If the mildew is not quite removed repeat the treatment.

SHOOTS OF THE MANETTI ROSE (*J. R.*).—When they first appear they have many thorns, but as the age of the plant increases the thorns disappear wholly, or nearly so.

NAME OF MANETTI ROSE (*Rosarian*).—It was raised from seed in the Botanic Gardens at Monza, near Milan in Italy, by Signor Manetti, and commemorates him.

NOTES ON SOME ROSES (*Q. Q.*).—"As you confess yourself to be a 'pupil' of mine, I will this once attend to your request, but, in future, such requests must come through the Editors. With regard to your culture I have no fault to find with it. It has been a very trying summer, yet a very fine one for fruits and flowers in the hands of able and diligent cultivators. The experience of England and Ireland could hardly be in all points the same. You say 'I have nearly got mildew under now, but the Roses on the north slope look very far from healthy; they are making very little blooming wood, and such blossoms as are on them are poor and stunted.' Does Mr. Radclyffe think that this arises from the aspect being not sufficiently warm for them, or does he think that it would be well to dig them up, and enrich the beds?" The above miseries may have arisen from a combination of causes, as extreme drought, root-sickness, poor cultivation, fungus, and extreme changes of temperature. Unless I saw the plants, and knew the sorts, and also knew the whole circumstances attending them, I could not determine the cause, or causes. I think it would be well to dig the plants up and deeply stir the ground under them. This will cause them to make new roots, and contribute towards their health for another year. Manetti Roses are none the worse of being moved annually, or biennially. Removal, however, unless carefully performed, interferes with their making roots independent of those of the Manetti. A few words about the Roses named—these are very good Roses, Maréchal Niel, Charles Lefebvre, Maréchal Vaillant, Souir des Anges, Alfred Colomb, Exposition de Brie, Prince de Portia, Prince Camille de Rohan, Duchesse de Caylus, François Lacharme, Charles Verdier, Madame Charles Wood, Souvenir de Comte Cavour (not quite full), Souvenir de William Wood, Dr. Jamain, Pierre Notting, John Hopper. The following are good:—George Prince, Dr. Andry, Jean Rosenkrantz, Lord Clyde, Charles Rouillard, much given to mildew, and not a late bloomer, Beauty of Waltham, and François Arago. Of the remaining Roses I may say that Rush-ton Radclyffe does well on a Briar, but not well on Manetti. It is a first-rate forcer. You cannot have Charles Wood true. It is a shy opener, of dark red colour nearly black. It is a good grower; but does not freely open. Louis XIV. grows well on its own roots, but miserably on a Briar or Manetti. Mdlle. Bonnaire is beautiful, but a wretched grower on Manetti. It grows better on a Briar. Substitute for it Marguerite de St. Amand; and Charles Verdier, Leopold Premier, and I may add, beautiful Julie Daran require shade on the southern side, and then they will bloom freely, and the last will retain its brilliant vermilion colour. Camille Bernardin has not grown well here, nor signalled itself yet. Madame Vidot, Madame Rivers, and Comtesse Cecile de Chabrillant are types of shape, and much given to mildew and orange fungus. The first two are delicate, require strong loam, a good summer and winter care. I have no doubt a hot south wall would be a good place for them. I have to-day potted seven sick plants of Madame Vidot, and one of Madame Rivers, and put them into my vinery to restrike their Manetti roots. I shall winter them there, and plant them out in spring. Professor Koch I have just rejected; it is not full, is a shy opener, and has never given me one good bloom for the last five years.—W. F. RADCLYFFE."

MANURING ROSES (*W. D. Scott*).—"I have never used either goose or sheep dung, dissolved in water, as a manure for Roses or plants generally. I should think they were both excellent manures, and that any quantity might be used in a diluted form without any deleterious effect.—W. F. RADCLYFFE."

PEAR TREES IN ORCHARD HOUSE (*Pears*).—The leaves are severely mildewed. Dust them thoroughly with flowers of sulphur; strew the sulphur also over the surface of the border, and paint the stems with a creamy mixture of the same as you mention for your Vines. Repeat the same treatment in the spring and as often as you see symptoms of the mildew.

PROPAGATING EVERGREENS (*T. R.*).—Hollies and Yews are poor from cuttings; indeed, the plants are of little value; besides, it is a tedious mode of propagation, and one in which there are many failures. They are best increased by seeds, and the varieties by grafting on the common sorts. Aucuba cuttings strike well. They would best succeed by your second mode—namely, under a hand-glass.

BUDDING MANETTI ROSE STOCKS (*Idem*).—The mode of budding Manetti Rose stocks does not differ from budding on the Briar, only the bud should be inserted below the surface, the stocks being earthed-up for that purpose. In budding, the soil should be removed, so that the bud may be inserted a little lower than you seem to have placed it—that is, on the part that has been covered with soil, which by keeping the stock from the atmosphere causes the bark to separate readily from the wood. We have not known "blacklocks" cut Strawberries, and do not think a dressing of lime and soot would prevent them doing so; but the latter is a most excellent manure for Strawberries. Your only plan would be to poison them. Chase's Beetle Poison is good for the purpose.

GLOIRE DE DIJON ROSE FROM CUTTINGS (*G. M.*).—The best mode of striking the cuttings is in pots in a hotbed, but it is now too late for that. You may still put in cuttings of such shoots as have formed their terminal bud, or lately bloomed. The cuttings may have two joints or three according to their length, and should be inserted in a warm situation, in sandy soil enriched with a little leaf-mould, and the surface covered with an inch in depth of sharp sand. Place a hand-glass on the sand, and gently press it down so as to mark the place it will cover, put in the cuttings about 3 inches from the outline of the hand-glass, and 2 inches apart. Give a gentle watering, cover the cuttings with the hand-glass and keep them close and shaded from bright sun. In a month admit air by degrees, and rather freely during mild weather, and to dispel damp in winter. A mat or other covering should be placed over the hand-glass in severe weather. In April the cuttings should be thoroughly hardened-off, and by the end of the month they will be fit for potting and should be potted-off singly into small pots.

ORANGE-TREE CULTURE (*Idem*).—Your Orange tree will succeed admirably in a greenhouse. It should be potted in March in rich turfy loam, with the addition of one-fourth very decayed manure or cow dung, and one-sixth sharp sand. Good drainage ought to be provided. In potting do not disturb the roots more than necessary, but pick away the old soil from about them. Do not give a large shift, but only use a pot large enough to contain the roots without cramping them, and add a little fresh soil. Be careful not to over-water, but keep the soil moist, and encourage growth by affording a moist atmosphere and syringing the foliage morning and evening. A temperature of from 50° to 55° at night would assist in promoting free growth. When the plant is growing freely keep it well watered, but do not give any water until the plant is in need of it, and then enough to show itself at the drainage. A few good spongings of the leaves with water in which soft-soap has been dissolved at the rate of 2 ozs. to the gallon will tend to keep the foliage clean and be very beneficial. A light and airy situation should be given it, though for a time after potting a rather shady situation, and a warm close atmosphere would be desirable, whilst at other times it will do well in an ordinary greenhouse.

EARTH CLOSETS—DISSOLVING BONES (*W. T.*).—To give plans, &c. would not be suitable to our pages. There are several pamphlets published on the subject, we believe. Any of the agricultural implement makers could supply you with a bone-crushing machine. To dissolve the crushed bones they must be put into a tub and frequently stirred in a mixture of sulphuric acid and water. The proportions are 12 ozs. acid, 12 ozs. water, 16 ozs. bones.

TWELVE FUCHSIAS FOR EXHIBITION (*Idem*).—Lizzie Hexham, Lord Elcho, King of the Doubles, Consolation, Harry George Henderson, Father Ignatius, Consolation, Catherine Parr, Minnie Banks, Conspicua, Mrs. Gladstone, and Rose of Denmark.

RIGHT TO REMOVE TREES (*Morpeth*).—You have no right to remove the trees, bushes, &c., unless you are a nurseryman. You should have taken a lease before you improved the land, or had an agreement that the trees, &c., should be valued at your outgoing. A landlord is always entitled to an improved rental.

CYLINDER VINERIES (*T. S.*).—If you write to Messrs. Rivers, Nurseries, Sawbridgeworth, they will give you information on all the subjects you inquire about.

AMATEUR FLORIST (*G. O. P.*).—An amateur florist is one who cultivates flowers for pleasure and not for profit. If any one cultivates flowers for the purpose of selling them, he is a tradesman—a florist. Merely selling a few surplus flowers would not render him a tradesman.

STORING WALNUTS (*F. M.*).—The nuts should have the husks removed, from which they will separate easily when ripe. Clean the nuts well if they are dirty, which they sometimes are, owing to the husk decaying on the nut, by rubbing them between cloths until dry and clean; then store them in earthenware jars, and place in a cellar, and in a somewhat damp place. In a dry place the kernels are liable to shrivel, and in a wet one they are apt to become of bad flavour from mouldiness.

ERECTING A FERNEY (*L. J. P.*).—A north aspect will answer very well for a fernery. We presume you have a wall, which would serve as the back of the lean-to, and in that case the cost of a lean-to would not be more than two-thirds that of a span-roofed house. It is not necessary to have front lights, and the ends need not be more glass than straight across to the back wall from the lowest point of the roof. The stove you name is not suitable. It would not injure the Ferns in the way you seem to think; but from its drying the atmosphere, those in proximity to it would not thrive. We advise a small saddle boiler, and a flow and return 4-inch hot-water pipe along the front and one end, which will be sufficient to keep out frost.

ROCHEA FALCATA NOT FLOWERING (*H. W.*).—We think you have "starved" your plant too well. You should have encouraged growth by a moist atmosphere and plentiful supply of water, pinching back all irregular growth, so as to form a compact plant. This treatment should be continued up to June, and when a good growth has been made the plant should have no more water than enough to keep it from flagging, and have full exposure, or a light and airy situation in a greenhouse or pit. This will secure the proper maturation of the growth on which the flowering depends. The soil should be a sandy turfy loam, and pieces of pots, charcoal, and sandstone may be mixed with it to keep it open. The

drainage should be good. Keep the plant dry when it is not growing. The Vine eyes should be entirely covered with soil to the depth named in our reply.

SOWING LILIUM AURATUM SEED (J. M.).—The seed should be sown in pots well drained and filled to within half an inch of the rim with a compost of two-thirds light fibrous loam, and one-third sandy peat. Make the surface smooth, scatter the seeds rather thinly, and cover with fine soil, but not to a greater depth than the diameter of the seeds. Give a gentle watering, and plunge the pot in a hothed of about 70°, or it may be placed in a house where there is a temperature of about 60° to 65°. In this it should be kept until the seedlings are fairly above the surface, then gradually harden them off, and remove them to a light and airy situation in a greenhouse. The seed should be sown in February or the beginning of March, or it may be sown now, the pots being kept in a greenhouse until the time named, then placed in heat and watered. We did not note how long the seeds were in coming up; but by autumn they had formed little bulbs, which should be potted off singly, without injury to the roots.

SOWING PHLOX SEED (Idem).—The seed of herbaceous Phloxes should be sown in pans well drained, and filled to within a little of the rim with a compost of two-thirds loam and one-third leaf mould. The surface should be made level, and the seeds covered lightly with fine soil, a gentle watering given, and the pans placed in a mild hothed. The plants will soon be up, and to keep them strong give air and place them near the glass. When they are large enough to handle prick them off in pans about an inch apart, return them to the frame, and encourage their growth; they will in May be fine plants, fit to plant out where they are to remain. The best time to sow is in the beginning of March.

CULTURE OF BOCCAINVILLEA GLABRA AND SPECIOSA (J. A.).—Your treatment is correct. They are both the better of being kept pot-bound, or of their roots being confined. *B. glabra* usually flowers at the end of summer; *B. speciosa* in the spring and summer, sometimes in winter, and on the well-ripened wood of the past year, as you say, whilst *B. glabra* flowers on the shoots of the current year. The pruning must therefore be altered to suit. *B. glabra* should have whatever pruning is required in spring, before new growths are made, and that pruning may consist in cutting back the shoots that have flowered to within a few eyes of their base, and in thinning-out and shortening the others. Every encouragement must then be given, and, if necessary, the plants should be potted, taking care not to use larger pots than the roots will fill well by the time the growth is complete. When a good growth is made the plant should have full exposure to light, and have but little water—no more than sufficient to keep it from flagging. *B. speciosa* should have the shoots thinned after flowering, be pruned back to encourage new shoots if wanted, and should be encouraged in the same way as *B. glabra*, keeping it dry in winter; indeed, after a good growth has been made, these plants should not have more water than is sufficient to keep the foliage from flagging. That, and full exposure, with a dry atmosphere, are essential to success. The temperature from fire heat need at no time exceed 60°, whilst in winter 45° will be ample. They are propagated by cuttings, taking off the short stubby shoots when half ripe, or when their bases become rather firm. A hothed is necessary and shade from bright sun, taking care not to over-water. They succeed best when covered with a bell-glass.

PLANT FAILURES (One in a Fir).—We think your success in growing Ferns should encourage you to persevere. Perfection is not yet attained by the most skilled, and we see no reason for your desponding of success. Persevere, and you will be successful and gain experience. We do not perceive in what way we can help you at present, but we think you have not provided sufficient ventilation for your greenhouse. Instead of one you should have at least three such openings as you name for ventilation, and the temperature you have kept up is much too high for greenhouse plants; 45° at night is quite sufficient at any time from fire heat. "Florist's Flowers for the Many" would suit you, which you can have free by post for five stamps from our office. The principles of gardening you may obtain from the "Science and Practice of Gardening," to be had post free from our office for 3s. 4d.

HEATING PITS (Evesham).—Your proposed flue, No. 1, would be sufficient to keep out frost. No. 3 is what we would prefer, as then the pit would be more generally useful when not wanted for bedding plants. The small flue would do, but except taking up more room there would be no objection to a flue 9 inches wide, inside measure. The best way to use such a pit would be to have a moveable stage above the height of the flue, and then when required the chamber could be turned into a hot-air chamber.

CUCUMBER HOUSE (A. Harris).—You will have plenty of light for Cucumbers from your roof and front glass, although the ends are wooden, but without any artificial heat it would be of little use planting out before June. As to trellis that would be advisable, and it should be not close to, but at least 15 inches from the glass. You may syringe freely in hot weather, and the more the water plays on the under sides of the leaves the better. Flower seeds of all kinds could be raised in such a house. Hardy annuals, &c., in February and March; half-hardy in April and May; and tender or tropical kinds after the middle of June. If we had such a house we would have simple means for keeping frost out.

GROUND VINERY PLANTING (W. J. E.).—Mr. Lane's grand orchard-house vinery had the Vines planted in the common soil, or rather in a few barrowloads of loam laid on the surface. In your case we would make a border for your barless vinery. We think one Vine at each end would be enough. By planting now strong fruiting canes you may take a light crop next season, but if you take much the Vines will be injured. But for the pleasure of having fruit the first season, we would advise canes not so large, and to be cut back after planting to a couple of feet or so in length, so as to secure strong canes with good established roots the second season. We do not consider the Trentham Black superior to the Hamburgh for this purpose, but we cannot speak from our own experience.

FLOWER GARDEN PLANTING (D. R. C.).—We like the proposed planting for 1869 best. If you have plenty of *Cineraria* use it as proposed for the centre of No. 1; if not, use Variegated *Pelargoniums*, as we would prefer to use the *Cineraria* in No. 9; others in No. 1, as proposed. If Variegated *Pelargonium* be used in No. 1, a different one should be used in 3, and the *Perilla* be stumped low. 7, *Perilla* will be too strong an edging for Cloth of Gold, and this latter rarely does well when fully exposed to the

sun. We would rather have *Perilla* or *Amaranthus* for the centre, and Cloth of Gold round, which would also come in well, and better with No. 8, Mrs. Pollock, with *Lobelia* and *Cerastium*. No. 9, we would surround *Coleus* with *Cineraria maritima*.

CLIMBERS FOR A CONSERVATORY (Bandon).—As to the house we are not sure of the position of the pillars, arches, &c., on the back wall. *Habenaria* and *Tacsonia* would do as proposed, but we would greatly prefer *Camellias*, which would look well at all times and require but little labour. For pillars and arches in front of the house we would recommend *Jasminum gracile*, *Kennedya Marryattae*, *Sollya heterophylla*, and *Kennedya dilatata*. For the trellis at the path we would have *Pasiflora cerulea* and *raemosa cerulea*. For your six pillars on the west wall we would advise *Roses*, *Marshall Niel*, *Gloire de Dijon*, *Climbing Deveniensis*, *Chloe Forestier*, *Solfaterre*, and *Cloth of Gold* or *Lamarque*.

SHRUBS FOR A TOWN GARDEN (C. E. R. 1.).—The part of your town garden having little sun we would devote to shrubs. The wall itself may be covered with *Jasminum nudiflorum*, which from its gay yellow flowers, produced abundantly at midwinter, is very interesting. The old *Aucuba* will do well, and a few plants of the Gold and Silver-edged *Hollies* would give you colour, and be enlivening to the dark green of the *Rhododendron*, which we would make the principal shrub. The *Kalmia latifolia* and *glauca*, *Ledum latifolium*, and *Andromeda floribunda* are very pretty, and delight in shade. *Ribes sanguineum* var., may be planted if you can give them sun, also the tree *Ponies*, whilst for bordering to the shady border *Vine* elegantissima is very neat and effective.

ANNUALS FOR SPRING BLOOMING (Idem).—The following will be off in good time, but ought to have been sown at the end of September or early in October:—Sweet Alyssum, *Calandrinia umbellata*, Candytuft, crimson, white, and purple; *Clarkia pulchella* and the white variety, *Collinsia bicolor*, *Erysimum Peroffskianum*, *Eschscholtzia californica*, *E. crocea* and *alba*, *Enchiridium grandiflorum*, *Eutaea viscidula*, *Gilia tricolor*, *G. tricolor rosea splendens*, *Gadeta roseo-alba*, *Leptosiphon densiflorus*, *Lupinus nanus*, *Nemophila maculata* and *insignis*, *Silene pendula*, *S. rubella* *alba*, and *Virginian Stock*, red and white. They will not be off by bedding-out time.

TOMATO CULTURE (Idem).—These will succeed against a south wall, the plants being raised and forwarded in heat and well hardened off before planting out. They may be watered in dry weather with liquid manure; guano at the rate of 1 oz. to the gallon of water is a good liquid manure. Chamber slops diluted with five times their volume of water will be a good manure, only give it to plants in active growth, and not too frequently, and when applying it give a thorough soaking.

PLANTS FOR CONSERVATORY WITH VINES (T. H. Jenkins).—Your house will be suitable for Ferns, at all seasons interesting, and the different kinds of foliage and variegated plants as *Agapanthus umbellatus* variegatus, *Cordylina indivisa*, *Draena australis*, *Hydrangea japonica* variegata, *Phormium tenax* variegatum, *Yucca aloifolia* variegata, and *Y. filamentosa* variegata. These, with the Ferns, will have a good effect even without flowering plants, and especially at a time when the flowering plants, on account of the Vines, will not be well longer retained in the house. To the above you may add of *Orchids*—*Cypripedium venustum* and *insigne*, *Cymbidium aloifolium*, *Arpophyllum giganteum*, *Epidendrum vitellium* majus, *Lysene Skinneri*, *Oncidium flexuosum*, *crispum*, and *leucochilum*, *Odontoglossum biconense* splendens, *O. pulchellum*, and *O. grande*. *Camellias* and *Azaleas* you will depend on for winter and spring, and *Epacris* are fine for winter. All may be grown well by your keeping them in the house until July when they may, as matter of necessity, be moved out, and returned to the house in September or October. A few others that may be treated in the same way are *Acacia armata*, longiflora magnifica, and *oleifolia elegans*; *Chorozema cordatum* splendens, *Coronilla glauca*, *Correas* Brilliant and *speciosa* major, *Cyclamen persicum* vars., *Cytisus racemosus*, *Indigofera decora*, *Linum trigycum*, *Monochartum ensiferum*, *Nerium rubrum* plenum, *Polygala Dalmaisiana*, *Rhododendron jasminiflorum*, and *R. Princess Royal*, *Witsenia corymbosa*, and *Vallota purpurea*. You must not omit *Primulas*, *Cinerarias*, *Calceolarias*, and *Pelargoniums*, and for early spring bulbs, *Crocus*, *Tulips*, *Hyacinths*, and *Narcissus* are desirable. Three of the best Vines for such a house are Black Hamburgh, Foster's White Seedling, and Trentham Black.

AMERICAN GARDENERS (R. S.).—We know of no publication containing a list of American gardeners and their employers.

PEARS FOR WALL (H. W. B.).—For the west aspect, Alexander Lambre, Beurre de Capiaumont, Colmar d'Été, Thompson's, and Vicar of Winkfield. No Pear succeeds well on a north aspect, you had better plant there Morello Cherries.

NAMES OF FRUITS (A Subscriber, Surrey).—1, Vicar of Winkfield; 2, Harcon's Incomparable; 3, Beurre de Rance; 4, No Plus Meuriss (H. E. W.).—1, Autumn Pearmain; 2, Royal Russet; 3, Dumelow's Seedling; 4, Golden Knob; 5, Christie's Pippin. You cannot have better than Marie Louise Pear for your south-west wall. (*Philoxeros*).—3, Manks Codlin; 6, Russet Nonpareil; 9, Wyken Pippin. These are all we can name of the very nice collection you sent. The others are varieties with which we have no acquaintance, and we should very much like to know something about them. (*J. L. D.*).—Apples: No. 1 Seedling, is a very handsome Apple; 2, also a seedling, is worthless; 4, Beauty of Kent; 8, Pomme de Neige. Pears: 1, Lewes; 2, Vicar of Winkfield; 3, Duchesse d'Angoulême. The Plum appears to be Jefferson. (*H. W.*).—Pears: 1 and 2, Quite decayed; 3, Chaumontel; 4, Passe Colmar; 5, Easter Beurre; 6, Glou Morceau; 7, Beurre de Rance; 8, Marie Louise; 9, Urbaniste; 10, Chaumontel. Apples: 11, Decayed; 12, Blenheim Orange; 13, Herefordshire Pearmain. (*T. W. Horne*).—Pear: Beurre Diel. (*T. G. R.*).—Your Pear is Napoleon. (*Henry & Son*).—Your Grape is Royal Muscadine, the Chasselas de Fontainebleau of the French. (*H. J. C.*).—Pears: 1, Passe Colmar; 2, Glou Morceau; 3, Passe Colmar; 4, Bezi Vœt; 5, Beurre Diel; 6, Passe Colmar; 7, Forelle; 8, Beurre Bosc; 9, Beurre de Rance; 10, Unknown; 11, Urbaniste; 12, Beurre de Rance. (*Sutton, Wiltshire*).—Apples: 1, Herefordshire Pearmain; 2, Scarlet Nonpareil; 4, Shepherd's Newington; 5, Oliver's; 6, Glory of Wilts; 7, Waltham Abbey Seedling; 8, Cat's Head; 9, Old Nonpareil; 11, Manks Codlin; 12, Dumelow's Seedling; 13, Ditto; 14, Rymers. Pears: 16, Uvedale's St. Germain; 17, Decayed. The others unknown. (*John Ingle, jun.*).—Apples:—1, Royal Russet; 2, Sam Young; 3, Ross Nonpareil; 6, Reimette du Canada; 8, Winter Strawberry; 9, Rymers; 10 and 11, Quite decayed; 12, Emperor Alexander; 14, Grange's Pearmain; 15, Hawthornden.

17, Waltham Abbey Seedling. The others we do not recognise at present. (*Centurion*).—Your Apples and Pears are a curious mixed lot, many of them are, no doubt, purely local sorts, which are to be found nowhere else. There are many such in this country which have no names. We certify what we can. A, This name is correct; B, Ditto; C, Too much decayed for us to name with certainty. It is, however, not Napoleon. D, Urbaniste; E, Yes. The true old Golden Pippin. F, Most probably a long form of White Doyenné; G, Is not Reinette du Canada. It is, however, unknown. It might be Reinette Grise dorée. (*H. Hare*).—Yours are by far the finest lot of Pears we have had sent to us this season. They are so exceedingly well grown that many of them are scarcely recognisable, so much are they altered from their usual character. We

should be glad to know how they have been cultivated. We name them as far as known. No. 3, Flemish Beauty; 5, Napoleon; 6, Beurré Diel; 7, Beurré de Rance; 19, Baronne de Mello, probably; 20, Brown Beurré; 23 and 31, Fondante d'Automne; 25, White Doyenné; 26, Comte de Lamy; 33, Doyenné du Comice, extremely fine; 18, Knight's Monarch; 37, Passe Colmar; 39, Marchal de la Cour; 40, Triomphe de Jodoigne; 44, Probably Beurré Clairgeau; 41, Bergamotte Drouot.

NAMES OF PLANTS (*Rosinini*).—Arctotis reptans. The late Mr. Beaton used to call it "The Frosted-silver Plant." (*M. K. Drummond*).—1, Purple Orache; 2, Agathe celestis variegata; 3, Nepeta cæsia. (*Julia*).—Capsella bursa-pastoris. (*J. S. H.*).—Hippophae rhamnoides.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the week ending October 6th.

DATE.	BAROMETER.		THERMOMETER.				Wind.	Rain in inches.	GENERAL REMARKS.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

DUBBING OR TRIMMING GAME STAGS.

GAME stags should not be dubbed until their combs are full grown, otherwise these will grow a little after the cutting. The usual time for dubbing is about the first Christmas, if spring-hatched birds, at which time the cock chicken becomes a "stag." In dubbing two persons are employed, one to hold the bird steadily and firmly in his hands, having the thighs and wings between his thumbs and forefingers, with the head of the bird pointing towards the operator. The two persons standing facing each other, the operator takes hold of the stag's comb, and with a sharp-pair of horse-clipping scissors takes off first one wattle and deaf ear at one stroke; then, turning the bird's head, still holding him by the comb, he with the second stroke takes off the other gill or wattle and deaf ear; and then, taking the bird by the back of the head and neck, or still holding him by the comb as some do, he with the third stroke cuts from the beak backwards, taking the comb neatly and quickly off close down to the head at one stroke, which completes the operation in about two minutes, and in three strokes if done by a clever operator. Some anoint the bird's head with sweet oil after the operation, but most persons consider this quite unnecessary, as a healthy bird heals very quickly, and in twenty days at farthest no trace of the operation should be visible, the whole head being quite healed and red again.

Some people cut from the back of the comb towards the beak, but I think this is backhanded and clumsy, as the stag can best be held facing the operator, and in cutting from the beak backwards the man stands in front of the bird, and can see both sides of the comb much better than in the other way. The comb should be taken off last (though some like taking it off first), as it affords a good hold to the operator. From six to twelve months old is the usual time for dubbing Game stags. Many operators say that they can cut better from the back of the comb to the beak, but in general I have seen it best done in the way I describe, and more quickly and neatly as well.

Game Bantams should be dubbed in exactly the same manner. The dark or gipsy-combed sorts stand the dubbing the best. These are the Dark Greys, Brown Reds, Dark Birchens, and the gipsy-combed Black Game fowls. The Piles and Whites, Blue Duns, and the yellow or daw-eyed sorts do not stand dubbing quite so well as the Black and red-eyed sorts. The light brown-eyed also, and bay-eyed sorts do not stand it so well as red and black-eyed birds, which are the gamest breeds and strains of all Game fowls.

Game stags should either be dubbed on their "out-walks," or be put out to walk as soon as dubbed, as if a number of them be dubbed in the home run, and then be put down together again, they will all begin to fight hard, and will probably injure themselves severely before they can be separated, as they do not know or recognise each other after dubbing, and will never run together quietly again, though they may have done so previously for some time.

Game stags should not be put out on a walk before they are six months old, and the best walks possible should be selected for them, on dry soils, not too bleak or windy in situation, and where from two to four of the smaller sort of farmyard hens are kept. Cottage walks if with a good run are the best, and maling or mill-yards, if not too hard strown, are in general preferable to any dirty farmyard, where they mix too much with pigs and aquatic fowls to keep clean enough. Piles, if high-bred, are, perhaps, more delicate than the darker breeds, and, therefore, require the best walks as a rule.

In preparing Game cocks for exhibition the small hairy feathers, called hairs or more technically "bristles," are all cut close off with the scissors, both at the top and sides of the head, but no trimming of the regular feathers is at all allowable. Some breeds have more of these bristles than others, the hardest breeds generally having most, Black-breasted Reds more especially.

Before exhibition some breeders rub the combs and faces of both cocks and hens with yolk of egg or milk, to give a smooth and shining appearance to the head and face, but healthy birds do not require this, and it is after all an artificial means of giving an appearance, and not to be recommended. Some leave the deaf ears uncut until the other parts have healed, but all should be trimmed or cut together.—NEWMARKET.

PAYING WITH POSTAGE STAMPS.

I VENTURE to call your particular attention, and more especially that of your readers, to the very objectionable practice on the part of exhibitors at poultry shows of sending postage and even receipt stamps in payment of entry fees. None but secretaries themselves have any idea of the trouble and inconvenience arising from this. Besides, if the exhibitors would look into the matter, they would find it exceedingly risky. Several cases have come to my knowledge this year of letters containing entries and stamps having either miscarried or been lost in their transit through the post office. I have myself, at the moment I write, nearly £100 worth of stamps, all of which have been forwarded to me as entry fees, and in sums of from 1s. to £2. Of course the stamps can be returned in prize money, but exhibitors do not like it, and they sometimes positively refuse to have them. Would it not save much trouble and anxiety if exhibitors sent the amount of their fees by means of a post-office order? I myself think so, for there is neither reason nor safety in a person sending, say 30s. worth of stamps by post in one letter, at the same time having to pay for an extra stamp or two in consequence of overweight, before he will take out a post-office order costing 3d., and incurring no risk.

I notice that at some shows stamps are only taken as fees at the rate of thirteen or fourteen to the shilling, but of course the order system would be much better, both to payer and receiver, if universally adopted. Then, again, every exhibitor could be paid his prize money in the same way, and he would thus have the pleasure of receiving money in place of penny, twopenny, and even sixpenny stamps.

If this is done it will, as I have before said, be more convenient to the senders, and at the same time considerably lessen the duties of many of our hard-worked and poorly-paid secretaries.—C. W. M.

[It would be wrong to refuse receiving postage stamps in payment of small sums, nor do we see any objection to paying larger sums with the same kind of paper money, provided the payer is required in every instance to pay thirteen penny stamps for every shilling due from him. The postage stamps will be taken by the Distributor of Stamps, and money given for them, after taking off a small discount.—Evs.]

MANCHESTER POULTRY SHOW.

THE eighth annual Show of Poultry and Pigeons at the Bello Vuo Zoological Gardens, Manchester, has just closed, and the arrangements have been quite as effective as those of former years. Few persons ever anticipated that so large and excellent a collection could have been brought together so early in the season by any Committee, who restricted the competition exclusively to birds of the current year. Nevertheless, this Exhibition proved one of the very best "chicken shows" which has ever taken place, though had it been held a few weeks later no doubt there would have been a considerable addition to the entries.

This season appears to have had a very unusual influence on poultry during the moulting time. The long drought so suddenly followed by heavy rains, coupled with cold, and of late even frosty nights, has had anything but a good effect on chickens, and from these causes severe colds and even roup itself have become far more common than for many years past. At Manchester we noticed with regret various pens of Spanish, Cochins, Game Bantams, and several specimens of Hamburgs, seriously suffering from decided roup. It would have been far wiser of their owners to have let them remain at home than to have confirmed the disease by the continued exposure of the birds, independently altogether of the injustice to exhibitors whose fowls were not ailing, having birds thus suffering placed in proximity to their own. In some of the worst cases the birds were returned at once to their owners, as being the best plan that could be adopted under the circumstances.

That great numbers of the pens shown were of extraordinary merit is beyond question, though after a few more weeks, the *Game* fowls especially, would have shown in much harder feather. The prize Brown Red pullets, and the *Game* fowls generally, exhibited by his Grace the Duke of Newcastle, Mr. James Fletcher, Mr. Halsall, and a few others, however, were penned in first-rate condition. The class for Golden-spangled *Hamburg* cockerels was one of the very best we ever met with, and the Golden-pencilled *Hamburgs* were also unusually good, but the Silver-spangled and Silver-pencilled were, as a whole, not by any means in a healthy first-rate condition. The Black *Hamburgs* were most meritorious throughout. The Manchester classes of Dark *Brahmas* were better than any hitherto shown, and were numerously filled. The light-feathered ones, on the contrary, were comparatively defective. *Cochins* were really good, and some of the Partridge-coloured were most extraordinary, whether viewed as to the correctness of plumage or early maturity. Of *Dorkings* and *Spanish* there were large classes of first-rate birds, but scarcely as yet in full feather.

Geese, *Turkeys*, and *Ducks* were extraordinarily good, and our readers may feel an interest in knowing the weights of some of the best of them, in a very close competition. The best Rouen *Drake* weighed 7 lbs. 15½ ozs.; the best two Rouen *Ducks*, 14 lbs.; the best Aylesbury *drake*, 8½ lbs.; the best two Aylesbury *Ducks*, 14 lbs. 15 ozs.; the best Embden *gander*, 23 lbs.; the best two Embden *Geese*, 38 lbs. 5 ozs.; the best *Grey gander*, 21 lbs. 10 ozs.; the best two *Grey Geese*, 33 lbs. 8 ozs.; the heaviest young *Turkey*, 14 lbs. 14½ ozs.

Of *Pigeons* there was a very full and very superior collection, which attracted a vast number of amateurs. The class for *Doves* contained a great variety of unique specimens, chiefly the property of Messrs. Jennison. The Show was remarkably well attended, and the weather was very pleasant and encouraging.

DORKING (Coloured, except Silver Grey).—*Cockerel*.—First, Mrs. F. S. Arkwright, Etwell Hall, Derby. Second, T. Briden. Third, J. Longland, Fourth, Duke of Newcastle. Clumber. Highly Commended, Hon. W. H. W. Fitzwilliam, Wentworth Woodhouse; J. Longland. Commended, Mrs. Bailey, Shooter's Hall, Longton. *Chicken*.—First and Second, Mrs. F. S. Arkwright. Third, Hon. W. H. W. Fitzwilliam. Fourth, Duke of Newcastle. Highly Commended, F. Schofield; T. E. Kell; J. F. Newton; J. Anderson, Meikle, N.L.; Mrs. A. Hurt. Commended, J. Anderson; H. Pickles, jun. Early. *Pullets*.—First, Duke of Newcastle. Second, Mrs. F. S. Arkwright. Third, T. Raines.

DORKING (Silver Grey).—*Cockerel*.—First, Rev. E. S. Tiddeman. Second, T. Briden. Third, T. Raines. Highly Commended, Rev. T. O'Grady, Ashbourne. Commended, T. Raines. *Pullets*.—First, D. Hardie. Second, Miss Milne. Third, Rev. E. S. Tiddeman, Brentwood. Highly Commended, Rev. T. O'Grady.

SPANISH.—*Cockerel*.—First, W. A. Hyde, Ashton-under-Lyne. Second, M. Ferrand, Dalton, Huddersfield. Third, W. R. Enll, Newport Pagnell. Fourth, Messrs. T. & E. Comber. Highly Commended, M. Ferrand. Commended, T. Briden; J. Biggin; H. Lane, Bristol. *Chicken*.—First, M. Ferrand. Second, H. Lane. Third, Messrs. T. & E. Comber. Fourth, E. Jones. Highly Commended, M. Ferrand; H. Beldon, Goitstock;

Burch & Boulter, Sheffield. *Pullets*.—First, J. Newton, Silsden, Leeds. Second, Burch & Boulter.

COCHIN CHINA (Cinnamon and Buff).—*Cockerel*.—First and Second, W. A. Taylor, Manchester. Third, C. Sidgwick, Ryddlesden Hall, Keighley. Fourth, A. Darby. Commended, J. Siebel, Timperley. *Chicken*.—First and Second, W. A. Taylor. Third, J. N. Bousley, Fourth, Hon. Mrs. Sugden, Wells. Highly Commended, C. Sidgwick; C. Leyland; D. Young. Commended, Mrs. M. Wilkin; H. Mapplebeck, Mossley, Birmingham. *Pullets*.—First, Mrs. A. Woodcock, Rearsby. Second, Bowman and Fearon, Whitehaven. Highly Commended, Hon. Mrs. Sugden; R. E. Brown; D. Young; A. Darby; H. Mapplebeck.

COCHIN-CHINA (Brown and Partridge feathered).—*Cockerel*.—First and Second, E. Tindian, Whitechurch. Third, J. K. Fowler, Aylesbury. Commended, Hon. Mrs. Sugden; J. A. Taylor. *Chicken*.—First, Second, and Highly Commended, J. A. Taylor. Third, E. Tudman. Commended, G. Lamb. *Pullets*.—First, G. Lamb. Second, H. Vaughan. Highly Commended, J. A. Taylor; H. Lingwood, Needham Market; J. K. Fowler.

COCHIN-CHINA (White).—*Cockerel*.—First and Second, R. Chase, Birringham. *Pullets*.—First, A. Williamson, Queensborough Hall, Leicester. Second, R. Chase. Highly Commended, G. Lamb.

BRAHMA POOTRA (Dark).—*Cockerel*.—First, Rev. J. F. Newton, Kirby-in-Cleveland. Second, Duke of Newcastle. Third, J. Siebel. Highly Commended, C. Leyland; J. P. Newton; Mrs. Burrell; Hon. Miss D. Pennant, Penrhyn Castle, Bangor; Mrs. A. Hurt; Mrs. Bailey; S. & R. Ashton, Mottram; E. Ryder, Harrytown. Commended, Mrs. Bailey. *Pullets*.—First, Hon. Miss D. Pennant. Second, K. Jopp, Aberdeen. Third, Mrs. A. Hurt. Highly Commended, Rev. E. Alder; Hon. Miss D. Pennant; E. Leech, Rochdale; Mrs. A. Hurt; J. Siebel; H. Lingwood.

BRAHMA POOTRA (Light).—*Cockerel*.—First, F. Crook, Forest Hill. Second, H. M. Maynard, Holmewood, Isle of Wight. Third, H. Dowsett, Pleshey. Commended, J. Pares, Postford. *Pullets*.—First, F. Crook. Second, H. Lacy, Hebdon Bridge. Third, A. O. Worthington, Barton-on-Trent. Highly Commended, J. Pares. Commended, H. M. Maynard.

POLISH (Any variety).—*Cockerel*.—First, H. Beldon, Goitstock. Second, H. Pickles, jun. Third, and Highly Commended, P. Unsworth, Loxton, Newton-le-Willows. *Pullets*.—First, H. Pickles, jun. Second, P. Unsworth. Third, H. Beldon. Commended, T. Walsley.

CRÈVE-CŒUR.—*Chicken*.—First, Hon. W. H. W. Fitzwilliam. Second, J. K. Fowler. Third, Col. Stuart Wortley.

HODDANS.—*Chicken*.—First, W. Fairs, Fixby Park, Huddersfield. Second, H. M. Maynard. Third, F. Heald, London. Commended, C. Leyland; Col. Stuart Wortley, London.

LA FLECHE.—*Chicken*.—First, J. K. Fowler. Second, J. C. Cooper, Cooper's Hill, Limerick. Highly Commended, Col. Stuart Wortley.

GAME (Black-breasted Reds).—*Cockerels*.—First, Duke of Newcastle. Second, J. W. Thompson. Third, C. Chaloner. *Chicken*.—First, Duke of Newcastle. Second, Rev. T. O'Grady. Third, J. W. Thompson. Fourth and Highly Commended, J. Fletcher, Stonelough. *Pullet*.—First, S. Matthews, Stowmarket. Second, Rev. T. O'Grady. Third, D. Hardie. Commended, C. Chaloner, Workson.

GAME (Brown and other Reds, except Black-breasted).—*Cockerel*.—First, T. Statter, Stand. Second, F. Sales. Third, J. Hodgson. Highly Commended, J. Fletcher; W. Clough. *Chicken*.—First, J. Fletcher. Second, F. Sales, Crowle. Third and Fourth, J. Wood, Wigan. Highly Commended, Rev. F. Watson. Commended, J. Wood; T. Statter. *Pullet*.—First and Second, J. Wood. Third, J. Hodgson. Highly Commended, T. Dyson, Halifax; T. Statter.

GAME (Duckwings and other Greys and Blues).—*Chicken*.—First, J. W. Thompson, Southwam. Second, J. Fletcher. Third, J. Halsall. *Pullet*.—First, J. Halsall, Ince. Second, J. Steel. Commended, T. Mason.

GAME (White and Piles).—*Chicken*.—First, J. Halsall. Second, C. Chaloner.

DUCKS (Rouen).—*Drake*.—First, J. Anderson. Second, Gunson & Jefferson. Third, T. Statter. Commended, T. Wakefield; Gunson & Jefferson, Whitehaven; J. J. Stott, Rochdale. *Ducklings*.—First, T. Burgess. Second, J. Wood. Third, Gunson & Jefferson. Highly Commended, T. Wakefield; E. Leech; T. Statter; J. J. Stott. Commended, T. Wakefield; D. Hardie.

DUCKS (White Aylesbury).—*Drake*.—First, J. Anderson. Second, Mrs. M. Seamons, Aylesbury. Third, R. Smalley, Lancaster. Commended, E. Leech; J. H. Stott; R. Smalley; J. K. Fowler. *Ducklings*.—First and Third, Mrs. M. Seamons. Second, J. K. Fowler. Commended, S. H. Stott; E. Leech.

DUCKS (Black East Indian).—First and Second, Rev. W. Serjeantson, Acton Burnell.

ORNAMENTAL WATER FOWL.—First, Second, Third, and Commended, J. Jennison, Zoological Gardens, Manchester. Highly Commended, J. Jennison; J. C. Wood.

GESE (White).—*Gander*.—First, T. Statter. Second, J. & W. Rostron. Third, S. H. Stott. Highly Commended, J. C. Cooper. Commended, J. Hodgson. *Gooslings*.—First, J. & W. Rostron. Second, E. Leech. Third, T. Statter. Highly Commended, S. H. Stott; Mrs. M. Seamons.

GESE (Grey and Mottled).—*Gander*.—First, Mrs. M. Seamons. Second, J. K. Fowler. Third, S. H. Stott. Highly Commended, E. Leech; S. H. Stott; Rev. G. Huxler, Stillingfleet Vicarage; T. Houlker. *Gooslings*.—First, Mrs. M. Seamons. Second, J. K. Fowler. Third, T. Houlker. Highly Commended, S. H. Stott; Rev. G. Huxler.

TURKEYS.—*Poult*.—*Cock*.—First, Second, and Third, W. Sanday, Holme Pierrepont. Commended, E. Ryder. *Hens*.—First and Second, W. Sanday. Third, F. E. Richardson. Highly Commended, E. Ryder.

HAMBURGH (Black).—*Cockerel*.—First and Third, C. Sidgwick, Ryddlesden Hall. Second, Mason & Walker, Denton. Highly Commended, W. Parr; Mason & Walker. *Pullets*.—First and Third, Mason & Walker. Second, Rev. W. Serjeantson. Highly Commended, W. Parr, Patricroft; J. Lancashire; Rev. W. Serjeantson. Commended, J. Lancashire.

HAMBURGH (Golden-spangled).—*Cockerel*.—First, T. Scholes, Hollinwood. Second, E. Brierley, Heywood. Third, N. Marlor. Highly Commended, T. Scholes; J. Mann, Stacksteads. Commended, E. Brierley; N. Marlor; J. Walker. *Pullets*.—First, E. Brierley. Second, H. Beldon. Third, J. Ogden. Highly Commended, J. Ogden; T. Scholes. Commended, E. Brierley.

HAMBURGH (Silver-spangled).—*Cockerel*.—First, J. Pickles, jun. Second and Third, J. Fielding. Highly Commended, J. Lancashire; J. Walker. *Pullets*.—First, J. Fielding. Second, H. Beldon. Third, H. Pickles, jun. Highly Commended, J. Lancashire; J. Fielding; J. Walker.

HAMBURGH (Golden-pencilled).—*Cockerel*.—First and Third, H. Beldon. Second, T. Sharples. Highly Commended, W. Parr; J. Walker; H.

Pickles, jun.; T. Wrigley, jun. *Pullets*.—First, H. Beldon. Second, W. Parr. Third, J. Walker. Highly Commended, J. Bowness; F. D. Mort. H. Pickles, jun.

HAMBURGH (Silver-pencilled).—*Cockerel*.—First, H. Beldon. Second, T. Sharples. Highly Commended, J. Walker; H. Pickles, jun. *Pullets*.—First, H. Beldon. Second, T. Sharples. Highly Commended, J. Walker.

GAME BANTAMS (Black-breasted Red).—*Chickens*.—First, F. W. Entwistle, Leeds. Second, Furness, Bamber, & Rhodes. Third, J. Crosland, jun. Fourth, J. J. Consens. Highly Commended, J. W. Morris; J. Crosland, jun.; R. Swift. Commended, H. Shumach; J. R. Robinson; E. Ryder. *Cockerel*.—First, J. W. Morris, Rochdale. Second, J. J. Consens. Third, J. Crosland, jun. Highly Commended, Furness, Bamber, & Rhodes. Commended, T. Raines. *Pullets*.—First, J. Crosland, jun., Wakefield. Second, H. Shumach, Southwell. Highly Commended, J. R. Robinson.

GAME BANTAMS (Brown and other Reds).—*Cockerel*.—First, T. Dyson, Halifax. Second, R. Swift, Southwell. *Pullets*.—First, J. Wood. Second, Duke of Newcastle. Commended, T. Dyson.

GAME BANTAMS (Any variety except Black-breasted and other Reds).—*Chickens*.—First and Second, J. Crosland, jun. Third, R. Swift. Highly Commended, H. Shumach. *Cockerel*.—First, T. P. Wood, Chesterfield. Second, H. Ashton. Highly Commended, Mrs. M. Hales; J. W. Morris. Commended, J. Steel; H. Shumach. *Pullets*.—First, H. Ashton, Polefield Hall, Prestwich. Second, J. Crosland, jun. Highly Commended, W. T. Entwistle; J. Crosland, jun.

BANTAMS (Any variety except Game).—*Chickens*.—First, H. Beldon. Second, Miss A. Woodcock. Third, W. H. Tomlinson, Birmingham. Highly Commended, T. Davies; N. Marlor, Denton. Commended, S. & R. Ashton.

PIGEONS.

POUTERS (Any colour).—*Cock*.—First, R. Fulton, Deptford. Second, A. H. Stewart. Third, F. Crossley, Elland, Halifax. *Hen*.—First, R. Fulton. Second, A. H. Stewart. Very Highly Commended, R. Fulton. Highly Commended, A. H. Stewart; J. Hawley, Bingley (Blue).

CARRIERS (Black).—*Cock*.—First and Second, R. Fulton. *Hen*.—First, G. Charnley, Preston. Second, R. Fulton. Highly Commended, F. Crossley. Commended, R. Fulton.

CARRIERS (Any colour except Black).—*Cock*.—First, F. Crossley (Dun). Second, J. Hawley (Dun). Very Highly Commended, G. Charnley (Dun); J. C. Ord (White); F. Graham. Commended, J. C. Ord, Fulmice (Dun and Blue). *Hen*.—First and Highly Commended, R. Fulton (Dun). Second, J. Hawley (Dun). Commended, J. C. Ord (White).

DRAGONS (Yellow).—First, C. Bulpin, Bridgewater. Second, J. W. Edge. Highly Commended, C. Bulpin. Commended, J. C. Ord.

DRAGONS (Any other colour).—First, D. Young (White). Second, H. Yardley, Birmingham. Highly Commended, R. A. Artindale. Commended, S. Dronfield; J. Hawley (Blue); J. C. Ord (White).

ANTWERPS.—First, J. Hawley, Bingley. Second, J. Thompson. Very Highly Commended, J. Crosland, jun.

JACOBS.—First and Second, J. Hawley. Highly Commended, E. E. M. Roys. Commended, R. Fulton.

BARNS.—First, Second, and Very Highly Commended, Capt. H. Heaton, Lower Broughton. Commended, Capt. H. Heaton; F. Crossley.

FANTAILS.—First, C. Bulpin. Second, J. W. Edge, Birmingham. Very Highly Commended, H. Yardley. Highly Commended, T. C. & E. Newbitt, Epworth.

TUMBLERS (Almond).—First, J. Fielding, jun. Second, R. Fulton. Very Highly Commended, F. Key. Commended, R. Fulton.

TUMBLERS (Mottles, Agates, Kites, or Self-coloured Tumblers).—First, F. Crossley. Second, R. Fulton. Commended, J. Hawley; J. Fielding, jun.

TUMBLERS (Beards, Balbs, or any other variety of Tumblers not before named).—First, C. Bulpin. Second, W. H. C. Oates, Eesthorpe. Commended, J. Fielding, jun.

NUNS.—First, C. Bulpin. Second, J. Hawley.

TURBITS.—First and Very Highly Commended, J. Hawley. Second, H. Mapplebeck.

OWLS (Blue and Silver English).—First, J. Crosland, Wakefield. Second, Rev. F. Watson. Very Highly Commended, J. Hawley; C. Bulpin. Highly Commended, Capt. H. Heaton; C. Bulpin. Commended, A. Jackson.

OWLS (Foreign).—First and Second, J. Fielding, jun., Rochdale. Commended, F. Crossley.

RUNTS.—First and Second, T. D. Green, Saffron Walden.

TRUMPETERS.—First, J. Hawley. Second, J. Firth, jun., Dewsbury.

ANY OTHER VARIETY.—First, J. Hawley. Second, H. Draycott (Frill-backed). Third, W. S. Loder. Very Highly Commended, J. Hawley. Highly Commended, Mrs. M. Hales. Commended, H. Yardley; C. Bulpin.

DOVES.—First and Second, J. Jennison.

Edward Hewitt, Esq., of Birmingham; and R. Teebay, Esq., of Preston, were the Judges of Poultry; and Dr. Cottle, of Cheltenham, for Pigeons.

GUISELEY AGRICULTURAL SOCIETY'S POULTRY SHOW.

At the nineteenth annual Exhibition of this Society, held October 3rd, the following awards were made:—

SPANISH (Black).—First, J. Thresh, Bradford. Second, J. Thresh, Windhill Cragg.

PHEASANT (Golden).—First, W. Drine. Second, J. Preston.

PHEASANT (Silver).—First, T. Robinson, Baildon. Second, T. Fawcett, Baildon. Highly Commended, W. Sugden, Thackley; H. Robinson, Baildon; T. Fawcett, jun., Baildon. Commended, J. Jennings, Esholt.

CAITTEPRAT.—First, H. Smith, Morton Banks. Second, J. Preston, Ollerton. Highly Commended, M. Scott, Cote.

GAME.—First, T. Dean, Keighley. Second, J. Steel, Halifax. Highly Commended, J. Hodgson, Bradford.

HAMBURGH (Black).—First, J. Preston. Second, C. Sidgwick, Ryddlesden, Keighley. Highly Commended, E. Baxter, Idle.

HAMBURGH (Golden-pencilled).—First, J. Smith, Gilstead, Bingley. Second, J. Barker, Allerton, Bradford. Highly Commended, J. Smith; W. Wormald, Guiseley; M. Scott.

BANTAMS (Any colour).—First, J. W. Wilkinson, Bradford. Second,

J. Riley, Hawksworth. Highly Commended, R. Mason, Skipton; J. Steef, Halifax; F. Steel, Halifax.

ANY OTHER DISTINCT VARIETY.—First, J. W. Wilkinson. Second, C. Sidgwick. Highly Commended, T. Dean; J. W. Wilkinson; A. E. Tee, Calverley.

ANY DISTINCT VARIETY.—*Chickens*.—First, H. Jowett, Idle. Second, J. Berry, Silsden. Highly Commended, J. Wilson; J. T. S. Eeck, Baildon; W. & J. Bairstow, Bingley; F. Lees, Guiseley.

DUCKS (Aylesbury).—First, J. W. Wilkinson. Second, Miss Newson, Yeadon. Highly Commended, Miss M. Robinson, Thirsk; J. Grunwell, Menston (White).

DUCKS (Rouen).—First, C. Sidgwick. Second, W. Bentley, Bradford. Highly Commended, J. West; J. Priestley, Guiseley; M. Scott.

PIGEONS.—*Antwerps*.—Prize, J. W. Wilkinson. *Owls*.—Prize, J. Thresh. Highly Commended, J. Steel.

JUDGES.—Mr. E. Hutton, Pudsey, and Rev. J. Bailey, Elslack.

ECCLESFIELD AGRICULTURAL SOCIETY'S POULTRY SHOW.

The twenty-sixth annual Show of the above flourishing Society was held October 1st. The following are the awards:—

DORKINGS.—Prize, G. Helliwell, Walkley.

SPANISH (Black).—First and Second, E. Brown, Sheffield.

COCHIN-CHINA.—Prize, H. Hobson.

GAME.—First, G. Helliwell. Second, C. Travis, Thurgoland. *Chickens*.—

First, G. Helliwell. Second, H. Hobson. Highly Commended, C. Travis.

HAMBURGHS (Golden-pencilled).—First and Second, T. Crookes, Owlerton. Highly Commended, H. Johnson, Ecclesfield.

HAMBURGHS (Silver-pencilled).—First, G. C. Armitage. Second, J. Homer, Grenoside.

BANTAMS.—First, J. Tomlinson, Sheffield. Second, J. Boler, Hiltop.

ANY VARIETY.—First, E. Brown. Second, W. Whiteley, Sheffield.

GAME COCK.—First, G. Helliwell. Second, C. Travis. Highly Commended, G. Lister, Ecclesfield.

GESE.—First, G. Helliwell. Second, S. Crawshaw, Caumes. Highly Commended, W. Shaw, Grange Mill Farm.

DUCKS.—First, H. Hobson. Second, G. Helliwell. Highly Commended, Miss E. Rhodes, Carr House, near Rotherham.

TURKEYS.—First and Second, Mrs. Booth, Brightholmlee.

PIGEONS.

CARRIERS.—First, E. Brown. Second, L. Higgins, Blackburn.

TUMBLERS.—First, R. Siddall, Portmahon. Second, E. Brown.

FANTAILS.—First, E. Brown. Second, V. W. Corbett.

ANTWERPS.—First, R. Cauwood, Ecclesfield. Second, R. Siddall.

JACOBS.—First, R. Siddall. Second, E. Brown.

CROPPERS OR POUTERS.—First, E. Brown. Second, K. M. Smith, Barnes Hall.

ANY OTHER VARIETY.—First, R. Siddall. Second, E. Brown. Highly Commended, W. Bannister, Brightside.

Mr. Hutton of Pudsey, near Leeds, was judge.

FARNWORTH POULTRY SHOW.

The fourth annual Show of Poultry in connection with the Farnworth (near Warrington), Agricultural Society took place on the 1st inst., when the following awards were made:—

YOUNG BIRDS.

GAME (Black-breasted Red).—First, J. Halsall, Ince. Second, E. Aykroyd, Bradford. Third, J. Holland, Manchester.

GAME (Brown-breasted Red).—First, M. Hornby, Scaplen, Winsford. Second, J. Wood, Wigan. Third, W. Roberts, Thorneyholme, Burnley. Highly Commended, G. Charnley, Preston.

GAME (Any other variety).—First, R. B. Riley, Ovenden. Second, E. Noble, Halifax. Third, J. Houghton, Upton. Highly Commended, J. Byron, Eccleston.

SINGLE GAME COCK (Any colour).—First, R. B. Riley (Black Red). Second, b. Biney, Manchester. Third, E. Shaw, Plas Wilnot, Oswestry. Highly Commended, J. Holland.

DORKINGS.—First, J. F. Newton, Kirby-in-Cleveland. Second, J. Stott, Healey, Rochdale. Third, H. Fickles, jun., Earby.

SPANISH.—First, Third, and Commended, T. Comber, Rainhill (Black). Second, J. Walker, Wolverhampton.

COCHIN-CHINA (Cinnamon or Buff).—First, J. Lee, Middleton. Second, G. Fell, Springfield, Warrington. Third, E. Brindley, St. Alkmunds, Derby.

COCHIN-CHINA (Partridge-feathered, or any other variety).—First, E. Tudman, Ash Grove, Whitechurch. Second, T. Stretch, Ormskirk. Third, J. Dearden, Halifax.

HAMBURGHS (Golden-pencilled).—First, J. Fielding, Newchurch, Manchester. Second, H. Fickles. Third, T. Wrigley, jun., Tonge. Highly Commended, S. Burn, Whitby.

HAMBURGHS (Golden-pencilled).—First, J. Chadderton, Hollinwood. Second, N. Marlor, Denton. Third, T. Scholes, Hollinwood. Highly Commended, J. Buckley, Taunton, Ashton-under-Lyne; S. & R. Ashton, Mottram.

HAMBURGHS (Silver-pencilled).—First, T. Wrigley, jun. Second, H. Fickles. Third, J. Fielding. Highly Commended, W. & J. Bairstow, Farncliffe, Bingley.

HAMBURGHS.—First, T. Wrigley, jun. Second, H. Fickles. Third, W. McMillan, Glossop.

PORCINI (Any variety).—First, H. Fickles. Second and Third, P. Unsworth, Lowton.

BRAHMA-POOTRA.—First, C. Leyland, Grappenhall. Second, G. Dixon, Whitehaven. Third, E. Leech, Rochdale.

GAME BANTAMS (Any colour).—First, J. Crosland, jun., Wakefield. Second, T. Eggleston, Halifax (Black Red). Third, L. Biney.

GAME (Any breed).—First, S. & R. Ashton. Second, T. C. Harrison. Third, W. H. Robinson. Highly Commended, N. Marlor.

GAME BANTAM COCK (Any colour).—First, J. Crosland, jun. Second, R. Halsall, Halewood. Third, Bonny & Davies, Blackpool (Black Red).

ANY OTHER DISTINCT VARIETY NOT BEFORE MENTIONED.—First, C. Loyland, Grappenhall. Second, T. Pilkington, Prescott (Houdans). Third, G. R. Rogerson, Liverpool (Golden Pheasant).

SELLING CLASSES (Any colour or breed).—First, E. Shaw. Second, A. Bamford, Tongo. Third, T. Comber, Raibill (Silver-pencilled Ham-burghs).

DUCKS (Rouen).—First, T. Wakefield, Railway View, Golborne. Second, R. Halsall. Third, T. Burgess, Macclesfield. Highly Commended, E. Leech; T. Houliker, Revidge, Blackburn.

DUCKS (Aylesbury).—First, E. Leech. Second and Third, Mrs. M. Sandons, Hartwell.

DUCKS (Any other variety).—First, R. Gladstone, jun., Broadgreen (Muscovy). Second, S. Burn, Whitley (East India). Third, T. C. Harrison, GEORGE, Medal, W. Mather, Raibill. First, Mrs. M. Seamons. Second, T. Houliker. Third, S. H. Stott, Rochdale. Highly Commended, E. Leech; R. Gladstone, jun.; Rev. J. C. Macdonald, Sefton Rectory, Toulouse. Commended, R. Gladstone, jun.

PROCONS.—Highly Commended, T. Lea, Whiston (Black Barbs).

The Judges were Mr. R. Teebay, Fulwood, Preston, and Mr. Joseph Hindson, Barton House, Everton.

YORK AND DISTRICT FANCY RABBIT SHOW.

The inaugural Show of this Society, held in the Friendly Societies' Hall, Castlegate, on the 2nd inst., was one of the best that has ever been held in York. The Rabbits exhibited were for the most part of the purest breed, especially in the open classes, whilst those shown in the classes limited only to members of the Society were very fine and of excellent quality. The entries amounted to sixty. Rabbits were sent from Birmingham, Hull, Leeds, Middlesbrough, Surrey, and Prestwich.

OPEN CLASSES.

LOP-EARED.—*Buck.*—First, M. Millington, York. Yellow Buck, age eleven months, ears 22½ inches long, 5 inches wide. Second and Highly Commended, M. Millington. *Sooty Fawn Buck*, age one year and six months. Commended, A. H. Easton, Hull. *Doe.*—First, M. Millington. Fawn Doe, age two years, ears 21½ inches long, 4½ inches wide. Second, G. Jones, Birmingham. Fawn Doe, age eleven months. Highly Commended, J. Ingham, Leeds.

LOP-EARED (Yellow and White Buck or Doe).—First, — Stainburn, York. Yellow and White Doe, age one year and four months, ears 21½ inches long, 4½ inches wide. Second, A. H. Easton. Yellow and white Buck, age two years. Highly Commended, J. Ingham.

LOP-EARED (Black and white Buck or Doe).—First, M. Millington. Black and white Doe, age one year and five months, ears 21½ inches long, 5 inches wide. Second, A. H. Easton. Black and white Doe, age one year and three months. Highly Commended, J. R. Jessop, Hull.

BUCK OR DOE (Any other colour not previously mentioned).—First, B. Hudson, Hull. Tortoiseshell Buck, age six months, ears 21½ inches long, 4½ inches wide. Second, A. H. Easton. Fawn Buck, age one year and four months. Highly Commended, W. Taylor, York. Commended, — Haisworth, York.

ANY OTHER VARIETY.—First, A. H. Easton (Silver-Greys). Second, G. Robinson, York (Angoras), age eight months. Highly Commended, S. A. Wylie. Commended, — Rayson, Prestwich.

CLASSES OPEN TO MEMBERS ONLY.

LENGTH OF EARS.—First, — Stainburn, York. Yellow Doe, age six months, ears 21½ inches long, 4½ inches wide. Second, — Stainburn. Fawn Buck, age three months ten days old.

BLACK AND WHITE.—First, — Hall, York. Black and White Buck, age five months 10 days old, ears 18½ inches long, 4½ inches wide. Second, M. Millington. Black and White Doe, age four months and eighteen days.

YELLOW AND WHITE.—First, — Hall. Yellow and White Buck, age five months ten days, ears 21 inches long, 4½ inches wide. Second, M. Millington. Yellow and White Buck, age five months. Highly Commended, — Hall.

TORTOISESHELL.—First, — Stainburn. Tortoiseshell Doe, age six months, ears 19½ inches long, 4½ inches wide. Second, — Hall. Tortoiseshell Buck, age, 4 months 3 days.

BLUE AND WHITE.—First, — Stainburn. Blue and White Buck, age seven months, ears 21½ inches long, 4½ inches wide.

GREY AND WHITE.—First, — Stainburn. Grey and White Doe, age three months ten days, ears 19 inches long, 4½ inches wide.

SELF-COLOUR.—First, — Hall. Fawn Buck, age four months three days, ears 19½ inches long, 4½ inches wide. Second, Highly Commended, and Commended, — Millington. Blue Buck, age four months eighteen days.

HEAVIEST WEIGHT.—First, — Stainburn. Fawn Doe, age five months one day old, 9½ lbs. Second, — Hall. Grey Doe, age five months ten days, 8½ lbs.

The judges were Mr. J. Hume, of York, and Mr. Fletcher, of Hull.

BEEES IN LANARKSHIRE.

I FIND the following paragraph in the *Hamilton Advertiser*. "The Bee-man" therein referred to has, I am happy to say, a worthy successor in his son, Mr. A. Pettigrew, of Rusholme, near Manchester, who has from time to time during the last quarter of a century perseveringly advocated the adoption of much larger hives than those generally used. I know not if this were an inherited idea, but the weights given below are sufficient of themselves to prove that bee hives in Carluke must be very much more capacious than those we are accustomed to meet with in the south.—A DEVONSHIRE BEE-KEEPER.

"BEEES AND BEE-HIVES.—This village (Carluke) is the 'head

centre' of bee-keeping and bee-keepers. It is situate in the centre of a parish of poor clayey soil, with minerals underneath. The orchards in the vale of the Clyde serve the Carluke bee-keepers much, and they do not fail to place their bees within easy reach of the fruit blossoms of these orchards; but the white clover fields of Carluke are much inferior for honey-gathering to those of adjoining parishes and counties. The weights of the hives at Carluke year after year indicate that their owners are greatly in advance of the bee-keepers of Scotland generally, and more than half a century before those of England, in the art of making most of bees—that is to say, their profitable management. In 1864, it is reported that one bee-keeper at Carluke made £40 off nine hives; and in the *Hamilton Advertiser* it was stated that another bee-keeper had a hive which yielded two swarms in 1864, their united weight being 328 lbs. In 1866, the heaviest hive of the parish was 140 lbs. This year many of the swarms are 140 lbs. each, and one weighed 168 lbs. The years 1864, 1866, and 1868, have been favourable for a good honey harvest. The half weights given of bee-keepers at Carluke may stimulate many readers to pay more attention to bees; but it may interest some of them to know how it is that this village is the 'head centre' of bee management. About seventy years ago James Pettigrew, a labouring man, became the most extensive bee-keeper that this country has seen, and for thirty years he was well known fifteen miles round Carluke as 'The Bee-man' by name. He died twenty-five years ago, leaving the legacy of his experience and practice to the active, intelligent, and earnest bee-keepers of his parish. These shrewd men have not stood still these twenty-five years; they have adopted several valuable improvements of their own—so few in number, that they ask, 'Who taught the old Bee-man all he knew?'—but still improvements which enable them to talk of weights of hives and pints of honey startling to other folk."

SHREWSBURY'S PORTABLE GAS OVEN.

GREAT are the advantages of the use of gas for cooking purposes, especially during the summer months, when fires are desirably extinguished as soon as cooking has been completed, but there has hitherto been one great disadvantage—namely, that the roasting and baking have been performed over the burning gas, thereby causing the article cooked to become impregnated with the vapour arising from the combustion of the gas. This disadvantage is entirely removed in the case of Mr. Shrewsbury's Gas Oven.

The oven is heated from the outside, with the inventor's patent burner, which, for the convenience of lighting is fixed on a swivel, and is made to open with the door immediately under the oven, and as the heat is carried all over the oven, the sides and top are kept at an equal temperature, while the fumes from the burnt gas are taken away by an outlet provided for that purpose.

The oven can be heated in a few minutes, and for roasting

meat or poultry, or for baking bread and pastry, cannot be surpassed. Each oven is supplied with a water dripping-pan, which, during roasting, is placed at the bottom of the oven, the joint or poultry being hung over it. This pan has the treble advantage of preventing the fat from being thrown on the sides of the oven; the dripping from being burnt and useless; and, by the steam from the water, of preserving the same moisture inside the oven as in the external atmosphere: thus, while the joint is thoroughly done and nicely browned all over, it is not burnt or wasted, as is so often the case in open fire-roasting.

The oven is so constructed that the underneath part can be used for baking potatoes, toasting bread, browning dishes, &c., while the cooking operations are being performed; the top of the oven also forms an excellent hot plate, on which may be fixed, if required, one or two boiling apparatus, so that roasting, baking, and boiling can be performed at the same time. Its portability is a great advantage, as it can be easily removed from one place to another, and requires no fixing; it is cheap in consumption of gas, costing only 1d. per hour when in use; there is no collection of soot, and the flues never require cleaning out.

BEE-KEEPING IN WICKLOW.

As you gave me advice in the spring about my bees, I am induced to send the following statement of the condition of my apiary, wishing to know whether you consider I have been successful.

In May I had three stocks, one of them (C) very weak. A sent off swarms on May 7th and 18th, the swarm of the 7th swarming again June 13th and 26th. B sent off swarms May 12th and 28th, the swarm of the 12th swarming again June 26th. C swarmed June 7th.

I obtained a Woodbury hive by your recommendation, and in it lived the swarm of May 18th. I have just succeeded in taking from it two full bars of honey; they came away quite easily, being made straight. From the other hives I have had two large glasses (Taylor's 4s. 6d.), weighing 8½ lbs. each, and three of a smaller size. The present weight of my hives, this year's swarms, varies from 27 lbs. to 33½ lbs., including hive and floorboard.

But now for my difficulties. My three stock hives up to some little time ago appeared all right, except that we observed wasps going in and out; but now C has not a bee remaining, and no honey. A and B have only a few bees, as many wasps, and very little honey; the combs all cut, and the floorboards strewn with powdered comb. Can the wasps have destroyed the bees? as I did not see dead bees about the hives: but there are always numbers of wasps about the apiary, and I fear they are robbing other hives. I have contracted the entrances as recommended in "Bee-keeping." Can you advise any further measure likely to check their attacks? I have put several crocks containing treacle and beer near the hives, and have destroyed numbers of wasps, flies, and moths, but I fear some bees also, though our gardener thinks they are a kind of large fly like a drone, of which we have had numbers on the flowers this year; but it is difficult to distinguish them when smeared with the mixture. We destroyed hundreds of queen wasps in the spring, thirty or forty a-day in our greenhouses.

I have some vacant places in my bee house. Could I venture to move in some of the hives at present on stands near? Would the bees in that case know where to find their own hives? I send some of the moths that we found in the treacle and beer, and will thank you to say if they are the bee moth so much spoken of.—L. RIALI.

[The moths which accompanied your letter were so much crushed as to render identification difficult. They are certainly not wax moths, but are probably *Agrotis segetum*, the larva of which feeds on the roots of the wheat plant, &c.]

Having taken two full bars of honey from your Woodbury hive, you should replace the bars and frames, and take care that its inhabitants have plenty of food to last the winter, bearing in mind that empty straw hives of this construction weigh with their floorboards about 20 lbs., and wooden ones nearly 30 lbs. when empty. The same caution applies, of course, to all your other colonies.

The loss of your three stocks is owing in all probability to their entrances being too near to those of other hives, a defect which is common to all bee houses, and which is very frequently fatal alike to stocks and swarms other than first swarms placed therein through the loss of their queens, which are liable to

mistake their hives on returning from their wedding flights. In contracting the entrances to your hives you have done all that is necessary to enable strong colonies of bees to repel the attacks of wasps. These latter must not be credited, or rather debited, with the destruction of your three old stocks, which we have little doubt was really owing to the cause already indicated, and that the wasps only aided robber bees in plundering the stores of the hives after their inhabitants had become incapable of effectually defending them. Any colonies which you may now wish to place in the bee house should be moved thitherwards, bit by bit, very gradually, whilst the bees are still active, and got into it in this way before winter; but if this be found impracticable they should remain until the spring.]

BEE-KEEPING AT CLOGHEEN, IRELAND.

HAVING but four stocks in the spring, I determined to allow each stock to give one swarm, and, by destroying all queen cells except the most forward one, immediately after the swarms had left, I have succeeded far beyond my expectations and reaped a bountiful harvest. One stock yielded 72 lbs. of beautiful honey in supers, also a swarm that now weighs 47 lbs. exclusive of the hive. Two others were nearly as good; the fourth produced its swarm on June 21st, and 27 lbs. in the super. Being obliged to drive the bees of this last hive on the 25th of August I was surprised to find 51 lbs. of honey, after securing brood, &c., for stocking another hive, and which I have succeeded in doing through the excellent instructions given by "A DEVONSHIRE BEE-KEEPER."

My hives are all home-made, square, straw inside, beared outside, with a half-inch space between, fitted with bars, &c., and covered with a board roof.

The best preventive of brood in supers that I have used, is to attach a good-sized piece of thick comb to the two or three middle bars of the super before putting it on.—G. BECKETT, *Shanbally Castle, Clogheen, Ireland.*

OUR LETTER BOX.

POULTRY TRESPASSING (*Inquirer*).—Give your neighbour a legal notice to keep his poultry from trespassing. If they trespass after that notice sue him in the County Court. The smallest damages recovered would suffice to make him prevent future trespassing.

BRAHMA POOTRA COCKERELS (*M. A. B.*).—We lean to No. 1. From your description we fancy No. 2 is a squat-set bird, while No. 1 has not only grown, but may again. Do not mislead yourself or us about the comb of No. 1. If it is a faulty one, it is a disqualification. In all breeds where the comb is a point, there is no hope for a defective one. Again, highly-feathered legs such as you describe on No. 2, are serious disadvantages. We do not admire the brown shade or patch on the wing, but we see few fine birds without it. Most of the birds good-coloured in the body have this on the wing.

BROODY HENS (*H. E. N.*).—There are no means of preventing a hen being broody, and it is very cruel to try. It is simply her nature, and a little patience will survive the annoyance. M. Jaque's book can be procured in London through any French bookseller. We bought ours in Paris, but we have never needed a French book that a foreign bookseller could not procure for us. The only extra expense is the substitution of shillings for francs.

PIGEON-KEEPING (*Experientia docet*).—We would say you can keep in a healthy condition in your space six pairs of large fancy Pigeons, or nine pairs of smaller; but remember crowding and quarrelling, ending in destruction of eggs, &c., always go together. Pigeons of high-class varieties are loose in feather from cold; and if neglected and not kept warm, consumption, "going light," and rot feather follow. A plastered floor, if a ground floor, would certainly be cold in winter. Have, at any rate, abundance of perches, like narrow stools, for the birds to avoid being much on the floor, and beware of wet from the birds' bathing. Set a small pan in a larger, and then remove both after they have had a bath, and this only in genial weather. Fanciers separate their Pigeons in the winter to prevent their breeding and so weakening themselves. It is said that removing the nests and boxes and all temptations to breeding does as well. A slight wire door, that you can make yourself and put across your loft, would suffice.

RUNT PIGEONS (*R. Barney*).—If you refer to the prize lists of some of the poultry shows you will see the names of the most successful breeders.

BEES IN A ROSETRY (*An Old Subscriber*).—There is no chance whatever of the hive bee injuring your roses. If you intend keeping bees somewhat after the ordinary manner, with the power, however, of putting in supers, you cannot do better than adopt Payne's Improved Cottage Hive, described in "Bee-keeping for the Many," but made somewhat larger, say 16 inches diameter, by 8 or 9 inches deep inside. If, on the other hand, you intend to go in for scientific bee-keeping, the Woodbury frame hive would be the best. As you live so near Exeter, why do you not call on Mr. Woodbury, who would, we are sure, be happy to give you every information in his power.

COMMENCING BEE-KEEPING (*R. Walpole*).—Sixteen inches in diameter, by 8 or 9 inches deep, inside measure, is a good size for flat-topped straw hives. Entrances, 5 inches wide, should be cut in the floor-board, and contracted when necessary by the insertion of movable blocks of wood. Buy "Bee-keeping for the Many," published at this office, whence you can have it free by post if you enclose five postage stamps with your address.

WEEKLY CALENDAR.

From observations taken near London during the last forty-one years, the average day temperature of the week is 51.9°; and its night temperature 40.3°. The greatest heat was 74°, on the 15th, 1861; and the lowest cold 20°, on the 21st, 1842. The greatest fall of rain was 1.04 inch.

ARRANGING AND PLANTING SHRUBS.

HAVING in previous numbers of this Journal given an extended list of flowering shrubs, it may be of advantage to intending planters to offer a few hints as to their arrangement and planting.

Shrubs may be arranged in straight or curved lines, and so as to form belts or masses of any width. It is not imperative that the border should be at all points of the same width; it may begin with a point,

and be widened as it extends until it is 30 feet or more in width, may then be narrowed, merely leaving enough ground to plant in, be again brought out with a bold swell, increasing the width, of course, be continued some distance, recede again, and in turn be again brought out. In some parts the border will be narrow, in others wide, varying in width the whole distance, but the outline must not have any sharp elbows, no long extension and abrupt termination of a bend, but begin, go on, and return in an easy curve. Nothing destroys the harmony of a plan so much as an improper bend or ungraceful curve. To avoid this there is nothing like beginning the curve soon enough, for it is of no use planting three-fourths of the way gracefully, and so as to be all you require, and then finding a sudden bend cannot be avoided, and that you have gone too far to make it gracefully or easily. The greater width of the border at some parts than at others will admit of a greater variety of subjects, also of a greater number of one kind, being planted than if the border were of one uniform width, which it ought not to be, except where the shrubs are intended as a screen to shut out the boundary wall or objectionable objects beyond. Although the hiding of the boundary wall is desirable—indeed, from the interior it should always be invisible—yet the border may, where it is desirable to have a view of objects or scenery beyond the boundary, be so narrow as to admit of none but shrubs of small growth, and yet so tall and dense in foliage as to conceal the boundary without obscuring or shutting out the view.

The border, then, should be wide enough at its narrowest part to allow of shrubs being planted that will not allow of the boundary being distinguished, and yet permit of a view beyond; whilst in parts opposite those objects which it may be desirable to hide, the border may be of such a width as to admit of shrubs (and when these are not sufficient, of trees at the back of the shrubs), which by their height and density of foliage will serve as a screen. There will, therefore, not only be variations in width but in height, but the gradation should be easy and graceful as the ground outlines; there should not be any abrupt termination of the taller kinds of shrubs, but a gradual ascent from the low to the high, and of descent from the high to the low. There may be, when the objects to be excluded are extended to a considerable distance, an extension of the taller sorts of shrubs beyond what there otherwise would be where there are no buildings or objects to be excluded, and this extension may terminate suddenly

and begin suddenly, space being left between to admit of a particular object being seen. This will to some extent prevent the monotonous appearance presented by a shrubbery of the same height, or a long continuance of shrubs of the same height; but it is well that the opening be formed of shrubs that are of spreading rather than pyramidal growth, as by the former it will be graceful, and by the latter too abrupt and violent.

The border varying in width, if these parts that are wide or narrow occur at regular distances, the result of the planting will be monotonous as regards height. This should be guarded against by forming some of the widest parts one-half or one-third the length they are in others; and so also with the narrow parts of the borders, they must not be of one uniform length, but the border must have narrow parts of various widths and lengths. This will prevent monotony of height and aspect, as a greater variety of shrubs can be planted, each mass distinct in itself, yet allied to the neighbouring mass, though different, all the masses harmonising so as to form dependant parts of the same whole.

The diversity of width will give scope for variety and for gradations in the height of different clumps or masses, for such they are, though continuous, and will afford different views, which cannot be too numerous: the extent of the ground will not be discoverable from one point of view; and the views, varying with the different points, will interest the observer. This will be the case with borders at parts 50 feet wide, more or less, in others 6 feet or less, the former width to allow of greater density of foliage and height of shrubs to conceal the walls, fences, or ill-placed disagreeable objects, and the latter to hide the wall or fence, and yet permit of a view beyond it. There will not, therefore, be any straight lines, but only curved ones; and for the observer to see the different objects the walks must follow the outline of the border, separated only by a margin of grass 18 inches or so in width, which width of grass verge must not be increased so long as the outline curves inwards nor when it recedes until one has passed sufficiently round the bend, so that when looking backwards the part traversed is not visible. Then the grass may increase in width as the border recedes, and if sufficient space between the walk and border be gained, a detached clump of shrubs may be introduced on the grass, but they ought to be low-growing, so as not to obstruct the view of the border, which must be continuous, unless broken for an object, or to admit of some new feature, which must not be incongruous, nor in any case be of a rugged character, but should be graceful.

These groups may differ from the background of shrubs or those in the border: if those in the latter are of dull, frowning, leafless, flowering shrubs, a clump of *Rhododendrons*, *Kalmias*, *Andromedas*, or other plants may be introduced on the grass between the walk and border of shrubs; whilst, on the other hand, if the background is cold from the prevalence of evergreens, the subjects of the clump should be warm, as the Gold and Silver Hollies, than which nothing can be more beautiful and effective. If the background is sombre, as Yews, it may be relieved, and

enhanced in solemnity by a specimen of the beautiful *Picea grandis*, and if the background is stiff and formal, the remedy is a specimen or group of some graceful plant, as the Pampas Grass. These groups or masses should be separated by glades, or intervals not planted, and so disposed as to form a whole. In some parts the walks should pass through the border, or it should be repeated on the other side of the path, and when the path passes between masses there must be intervals to permit of groups of objects being seen, artistically prolonging the perspective. These masses should be varied, both in disposition and in subjects, but nevertheless allied, so that they may harmonise with neighbouring masses.

The masses, as a rule, should join the walk, being separated only from it by a grass verge, and may go alongside the walk 30 or 40 yards, or as many feet, varying in width the whole distance, for whatever the form of the clump may be on its either side, on that next the walk the same width of grass must be maintained the whole length. The mass may begin with a single tree or space for that, widening as it proceeds until it is 20, 40, or 60 feet wide, or it may be any mean between these, then be brought round with a bold swell, and back again in the form of part of a circle, terminating a little further than the bold part stands out. This will give crescents or part circles on the opposite side to the clumps—excellent spaces of grass in which to place specimen plants contrasting in habit or hues of foliage, serving as connections between the masses or parts more or less distant from each other, and the defect of monotony, ever apt to creep in, will be greatly decreased.

To repeat once more to the boundary border. As already stated, the border may be widened to shut out objectionable objects, which increased width need not necessarily detract from the beauty of the interior, but though limiting the extent of view, will enhance rather than detract from it; and the border may also be narrowed to admit of objects of interest and to afford diversity of view. This should not be carried too far, for one grand effect is preferable to a multiplicity of minor ones: at the same time diversity of form and subject pushed to the extreme is worse than repetition; the latter greatly increases the apparent extent, but diversity contracts it, and can only be permitted in continuous arrangements. Repetition and distinctness of view are productive of an agreeable effect, but diversity and indistinctness of view are destructive of effect. Shrubberies, where the aim in planting has been to secure a great variety of subjects and much diversity, are less in appearance than those formed with a due regard to distinctness of view, contrast of form, height, colour, and repetition, the latter making the space to the eye larger than were an equal number of varieties planted in place of the like number of one species or variety only.

The border, I was about to remark, may be widened to give space for planting to shut out unsightly objects, and it may be doubled or trebled in width to afford shelter; for as the wall or fence is a protection to the shrubs, so also must the shrubs be made to shelter the plants which they in a manner enclose. Without such helps in breaking the violence of winds, and diverting cold currents of air, many plants called hardy would be swept away; but such are grown by a judicious arrangement of the shrubs next the boundary, and planting them more thickly at the points whence come the coldest and strongest winds. By planting a thicket of Blackthorn on a bleak hillside, behind it may be grown a group of Laurels or Aucubas; and so by planting a thick belt of shrubs, putting the hardiest at the back in the parts most exposed, we obtain the shelter necessary for the most tender of so-called hardy plants. These increased widths of the shrubbery will not detract from the harmonious effect of the internal arrangements but enhance it, as from a greater breadth of shrubbery we secure richness, distinctness, and massiveness, the last being especially productive of effect. Isolated specimens never have the effect of a mass, though they appear advantageously when used as connections between masses, being then refreshing; but frequently repeated they almost always present a certain degree of monotony.

At the most distant parts, and especially near the entrance, deciduous shrubs should predominate, for in the distance they are not so black and frowning when leafless, nor is their bareness so easily discerned as when near; whilst in summer, when at a distance, their lively foliage and gay flowers do not form so great a contrast to the evergreens which, as a rule, should be near, and though chiefly in masses, yet they must be in proportion to the masses of deciduous shrubs. The groups of evergreens may be in one spot, but it should be borne in mind

that they form a distinct view, and should be so arranged as to constitute a whole of themselves. When, however, masses of deciduous and evergreen shrubs occur in the perspective, the evergreens will not be in keeping in a large space where masses of deciduous shrubs abound. This may be remedied by multiplying the masses of evergreens, but it is not necessary that they should occupy space corresponding to that which the deciduous shrubs have, it being necessary to establish between the evergreens the same or a similar correlation as is required by the deciduous shrubs, therefore, their forms should recur at suitable intervals. To have a good effect the evergreens must in this case be interspersed with the leafless shrubs.

Evergreen and deciduous shrubs rarely look well together, but for variety a few evergreens may be interspersed among the deciduous shrubs. Generally, however, when evergreens and deciduous shrubs compose the same groups the latter should be planted in the distance, at the back of a border or in the centre of a group, the evergreens being placed in front. Clumps of this class, also borders, may occur near the entrance, and recur by the mansion, for these are the most distant points of view, and their indistinctness will not be so manifest as in the separating and connecting masses, which ought to be as distinct as possible. The intermixing of evergreens with deciduous shrubs is always bad, and yet evergreens are too dull in summer unless enlivened by intermixture with flowering shrubs; whilst in winter nothing is so cold as a frowning mass of deciduous shrubs; therefore, to give freshness in winter evergreens may be rather extensively intermingled with the deciduous subjects; whereas, near the mansion, the masses may be of a mixed character, but nothing must be done without harmony.

In front of the windows, but not too near, small groups of the better sorts of evergreen flowering shrubs ought to be planted, but unless this can be done without destroying the other parts of the design, or in itself be a distinct feature, it will be well to omit it, for nothing is so ugly as grass cut into all manners of fancy shapes, nothing so beautiful and effective as a broad expanse of grass, the finest of all evergreens.—G. ABBEY.

(To be continued.)

NEW ROSES.

"They come! They come!" and the inquiry on all sides is, "What will they be?" We have had for years to hear the high-flown praises of foreign Roses, but let Rose-growers be sure that ere long they will have to decide on the merits of English as well as foreign ones. Hitherto the former have been few, but the conviction has forced itself on some minds that after all Rose hews will ripen in England, and good seed can be obtained. I saw not long ago four or five large beds of seedling roses in one well-known nurseryman's grounds, and I hear of others; while this year has been so favourable to the ripening of seed that many others will be trying their "prentice hands" at it. But for the present we have to do with foreign Roses. The John Hoppers, Mrs. Wards, Lord Clydes, Dukes of Edinburgh are few and far between; while the Souvenirs, Comtesses, Ducs, and Madames are as plentiful as blackberries.

When I was over in Paris this year the season was so far advanced that I was unable to see many of the novelties. I saw, however, several of the Rose-growers—Margottin, Charles Verdier, Eugène Verdier, &c. The first has three new Roses, I believe; Charles Verdier three also, and Eugène, *mirabile dictu!* none at all. Of those of which I heard most from all growers was one which is to be sent out by Charles Verdier, called *Thyra Hammerik*. It was raised by an amateur, and is, I am told, a vastly improved Duchess of Sutherland, and a flower of great beauty; while a bloom which I saw of *Souvenir de M. Portemer*, sent out by my old friend Margottin, gave promise of great excellence.

I have received two lists from the Lyons raisers, Ducher and Guillot fils, and these names have been favourably before us the last two or three years, for Antoine Ducher, Madame Margottin, La France, and Bouton d'Or have established themselves as favourites; hence we may have a reasonable hope that they may again have something good to offer us.

DUCHER.

La Tulipe (Tea).—Vigorous growth. Flowers large, full, and well formed, white tinted with rose, and sometimes with lilac. A plant of grand effect.

Marie Ducher (Tea).—Vigorous habit. Flowers large and well formed, very bright rose. Superb novelty.

Monplaisir (Tea).—Very vigorous. Flowers very large and very full, very deep salmon yellow. This variety, the issue of *Gloire de Dijon*, has the vigour of that plant, with flowers equally beautiful, but of a deeper colour and very rich.

Perfection de Lyon (H.P.).—Branches vigorous and erect. Flowers very large, full, cup-shaped, rose, with the back of the petals lilac.

Nardy Frères (Hybrid Portland?).—Very vigorous. Branches strong and straight. Flowers very large, full, and well formed, beautiful violet rose, with slate colour on the reverse of the petals.

GUILLOT FILS.

Madame Céline Norrey (Tea).—Very vigorous. Flowers very large, very full, and opening well. Reverse of petals purple red; centre, tender shaded rose. Very beautiful variety.

Mademoiselle Adrien Chirtophle (Tea).—Very vigorous. Flowers large, very full, coppery yellow, strongly shaded with rosy peach, sometimes of a beautiful deep yellow. By the variation of its colours this variety produces a magnificent effect.

Mademoiselle Marie Sisly (Tea).—Very vigorous. Flowers large, very full, globular, yellowish white, deeply bordered with lively rose. Superb.

Marginata (Noisette).—Very vigorous. Flowers medium-sized, very full, well formed, very brilliant yellow, of an entirely new shade of colour, broadly bordered with pure white shading off to rose, and producing a magnificent effect. Superb variety.

Madame Jacquier (H.P.).—Vigorous. Flowers very large, well formed, size and shape of the *Rose la Reine*, a beautiful bishop's purple. Very fine.

I need not say that the descriptions are not mine, but the raisers'; and I can only add what I daresay will strike every one, that if they at all are borne out by the flowers themselves, that they will be very great acquisitions. "*Nous verrons.*"—D., *Deal*.

GRAPES SHANKING AND SPOTTING.

In my opinion there are two causes of Grapes shanking—a deficiency of sap, and vitiated sap. The deficiency of sap may result from the great disparity between the temperature of the ground in which the roots are situated, and that of the house where the foliage and fruit, in the case of outside borders, are growing—a difference very often of 10° between the mean temperature of the house and that of the border. In a hot dry day the leaves and fruit will throw off moisture rapidly; but the roots furnishing sap slowly, too little will be supplied to meet the requirements of the expanding fruit; the footstalks of the berries will therefore shrivel or become ulcerated, and a complete stoppage of the communication between the roots and the berries will be the consequence, ending in the shrivelling of the berries.

Yet that in all cases is not the cause of shanking, for the condition of the roots may be such that they will supply sap fast enough, or there may be enough stored up in the stems to meet any sudden demand of the expanding fruit; this, however, can only be the case where the roots are in a medium favourable to the formation and preservation of the fibres and their points, or spongioles. Shankng, therefore, may not be the effect of too great a difference between the temperature of the soil and atmosphere; but the conditions unfavourable to shanking are elevation, dryness, and openness of the border, which are essential to the preservation of the fibres in health until the crop is mature, whilst the causes predisposing to the disease are lowness, wetness, and closeness of the materials of the border. Most outside borders have a tendency to cause shanking, for however dry they may be rendered by drainage and the materials of which they may be formed, yet very wet and cold weather, when the fruit begins to colour, may so retard root action as to induce shanking through an insufficiency of sap, arising from inactivity of the spongioles; but a dry scorching summer like the last will be most favourable to low, close-made borders.

A deficiency of sap may also result from the border being not only outside, but also below the level of the surrounding ground, and deep, rich, and imperfectly drained. This is generally the case when shanking is most severe. Than roots situated deep beneath the surface, and in a manner shut out from all sun and atmospheric influences, in conjunction with excessively rich soil, nothing further is required, except a period of cold rainy weather when the Grapes commence ripening, to cause the speedy destruction of the fibres, never

very plentiful. The supply of sap being thus rendered insufficient for the expansion of the fruit, as a consequence the berries shank. Examine at what time we may the roots of Vines situated in a deep, rich, low, wet border, we shall find them little better than so many bare sticks with a few fibres at the ends, in winter almost entirely rotten and dying back; and what can we expect but that similar destruction of the fibres will take place in summer when the same conditions of coldness and wet present themselves? Too great a depth of soil; roots too deep; soil wet, too rich, and cold, in comparison with the temperature in which the branches and fruit are situated, will destroy the fibres and cause a deficiency in the supply of sap, owing to which the footstalks of the berries or parts of the bunches will become ulcerated.

An insufficiency of sap may also result from depriving the Vines of too much foliage, either in the current or the previous season. It is not unusual to keep vineries warm and moist, with no great amount of air, after the fruit has set, in order to secure root action. A great breadth of foliage is produced, and when the fruit begins to colour, or a little before, a great part of the leaves is suddenly removed under pretences of allowing the fruit to become well coloured, and thus the foliage not being in proportion to the fruit and to the roots, it cannot assimilate the extraordinary amount of sap driven into it, hence the roots are rendered inert, and their destruction follows, either when the weather proves wet and cold, or a good supply of water is given to help the second swelling. The roots are now gone but more air is given, the evaporation from the leaves becomes excessive, the roots do not supply sap fast enough for the swelling fruit, and shanking of the footstalks of the berries and bunches follows. This is not so common a cause of shanking as coldness and wetness of the border, but it does sometimes occur with Vines planted in an inside border.

With regard to vitiated sap, in vineries where the borders are inside shanking is not wholly unknown. I have seen Grapes shank under what we may term very unfavourable conditions for the occurrence of the disease, and notwithstanding every precaution taken to guard against it. I fully believe the Vine to be no feeder on any strong manures that are often used in making Vine borders, the roots not taking up the supply of food as decomposed or rendered available, so that the soil not only becomes excessively rich, but sodden, sour, and deprived of air from its closeness; it follows that the spongioles take up food in a vitiated state, and the plant being unable to digest it, disease ensues as a necessary consequence. The sap may be vitiated by excessive watering, too rich soil, and the border being deprived of air from closeness of the materials employed, and this vitiated sap produces much wood and long loose bunches of fruit with wiry footstalks, the berries swell very irregularly, and when they should become large, plump, and well-coloured, they cease to swell, remain red, shrivel, and are sour. A soil open, well drained, and poor rather than rich, would prevent this cause of the disease. Our best Grapes are not grown in borders measured by their depth and the quantity of manure they contain, but by the openness of the soil, the slow decomposition of the manurial substances, and the soil's dryness and shallowness. Afford the Vines a warm, dry, and open soil, and shanking will be less frequently seen.

The varieties I have noticed most liable to shank are Frontignans and Muscat Hamburg. I believe the last-named to be a splendid Grape, but it is most difficult to grow. I wish we were all fortunate enough to have it in the fine condition it is grown by Mr. Pearson, of Chilwell Nursery, but I think it might be greatly improved by grafting on the Black Hamburg stock. I noticed the Vine borders at Garston Vineyard during a visit paid in August, and Mr. Meredith's intelligent foreman informed me he had never seen any Grapes shanked there, and I could see by the borders and the Vines that every precaution had been taken against that evil. The drainage of the outside borders rested on the ground level, and instead of a brick wall, as there is in most cases, turf was packed round the outside, so that there was nothing to prevent the air passing freely through the border from top to bottom, and this, in my opinion, is a great secret in the successful cultivation of the Vine. In the houses the Vines looked most vigorous and healthy, besides bearing an excellent crop of highly finished bunches. One house was devoted entirely to Mrs. Pince's Black Muscat, and one Vine nearly filled the house. The foreman informed me it was a very small cane planted in 1867, and this year at the time of my visit (August 21st), it was bearing twenty-six bunches, I should say nearly

averaging 1 lb. per bunch, and highly coloured; in fact, well finished in every respect.

I fully concur with the high opinions passed on Mrs. Pince's Black Muscat, and think it will prove a valuable addition to our late-keeping Grapes.—CHARLES ROBERTS, *Dorfold Hall*.

MADAME FILLION ROSE.

I AM not vain enough to suppose that any remarks I make upon the article signed "Q. Q.," appearing in your number for September 24th, would receive much attention, but I cannot refrain from making one suggestion, which I hope "Q. Q." will adopt—that is, do not discard Madame Fillion. The first year I grew it my opinion coincided with that of "Q. Q.," but last year I was truly thankful I had preserved it. Its colour, which is certainly a rose of a beautiful hue, was decidedly good, its form striking, and I can only say everyone who came to see my Roses exclaimed when they came to Madame, "Oh! what a lovely Rose." From June to September I dote upon having a Rose in my button-hole; whenever I could pluck one from Madame Fillion I did so.—AN AMATEUR GROWING 150 VARIETIES.

THE CEDAR OF LEBANON AND DEODAR.

AMONGST the trees to which Holy Writ and individual beauty have combined to give more than ordinary interest, the Cedar of Lebanon must assuredly take the pre-eminence. Its beauty, utility, and the district whence it comes have united to give it a charm which, perhaps, no other tree possesses, and its uses and abode have lost none of their interest since the latter has been more fully known, and the tree itself has been transported to almost all the countries of the globe, where there is a chance of its succeeding. In our own country it has long been a favourite, and at no time more so than at the present, when it has so many competitors; and, probably, a century hence may diminish the number of these rivals, as it is very questionable whether many of them possess that robustness of constitution requisite to adapt them for a climate like ours, so very different from those they came from. On the other hand, some of the earliest-introduced specimens of the Cedar of Lebanon, although rivaling in size our indigenous trees, look as if they would also equal them in longevity and the other features that give majesty to a tree.

A sort of poetry is also attached to this noble member of the vegetable world; its name is learnt in childhood, is familiar to all ages and classes, and when we meet with a majestic specimen of this tree, our admiration of it is increased rather than diminished by the recollection that its native home is so many hundreds of miles away, and in a position so different from those where it is usually met with here. Other and not less remarkable features of interest are presented by the Cedar of Lebanon, it being noised abroad, and that too with a strong appearance of truth, that this tree, to which we had been assigning a site only on the mountain frontiers of the Holy Land, has its counterpart many thousands of miles away in the interior of the great Asiatic continent, and at least a thousand miles from any sea coast, while the base of Lebanon is not far from the sea. Several thousands of feet difference in the elevation would also imply that the trees thus found widely apart could not have had a common origin. At the first introduction of the Cedar from central Asia, it was never dreamt that its relationship to the Cedar already amongst us would or could be pushed so close as it has been, yet such is the case; and as the similarity of the Cedar from the distant Himalayas to that of Lebanon becomes yearly more and more apparent, the opinion gains ground that they are one and the same species, varied only by the circumstance of their long abode in their respective positions.

The opinion that the Deodar and Cedar of Lebanon are both the same species has become more widely entertained since the specimens of the former have attained a larger size and assumed more of the rigidity of the Cedar of Lebanon, losing at the same time that pendulous habit which forms the characteristic difference. Some specimens we have here seem passing gradually from the one Cedar to the other, while parts of trees still more show the same change going on. Leaving this, however, for futurity to determine, it is not a little singular that a tree of such scriptural interest should also be equally an object of veneration to heathens, the Cedar of the Himalayas being held in no less regard by the tribes inhabiting the rich

and interesting country lying at the base of the tree's mountain home, than the Syrian Cedar was in patriarchal times. Probably one of the causes of the respect paid to this tree in both instances is a property for which the tree is remarkable, and one which must have addressed itself forcibly to a primitive people, and that is the durability of its timber.

From the limited quantity of Cedar timber that has found its way into this country, it has not yet had that fair trial of its merits which other woods have had, but enough of it seems to be known to prove that it is never likely to attain a high place among the woods adapted for making ornamental furniture, for neither in point of beauty nor adaptability to the purpose can it be compared with some woods that we possess, while for building it is hardly likely ever to compete with the Pine and other timber which we have from northern Europe and America. There is one merit, however, which it possesses, and which places it on a level with the best woods we have—its durability is equal to that of any known timber, and it is, doubtless, on that account, that Solomon was directed to use it in the building of the Temple; and I believe that trees of much smaller growth than those usually employed for building purposes, nevertheless cut up into scantlings that will equal, if not excel those of the best Pitch Pine. The wood does not seem to work up well into furniture, being liable to split, and being less ornamental than many others. Its durability would appear to be due to the large amount of resin which it contains, and which it does not part with so readily as many of the Pine tribe. This circumstance, I believe, also secures to it the fragrance that delights many, and which, doubtless, was no little recommendation to it in the early ages of the world, when paints and varnishes were less thought of than they are now, and it would be difficult to say the ancients were wrong. Paint has been much less used during the last twenty years in the fittings of churches and dwelling-houses than formerly, and it is probable that thick coatings of varnish, which have in some cases been substituted for it, will give way also; at any rate, the opinion that these substances maintain durability in all cases seems to be less generally entertained. In some instances, doubtless, they are to a certain extent beneficial, while in others they are as certainly a source of premature decay, and unpainted timber in a sound state can be met with in places some centuries older than any bedaubed with colouring.

As Cedar wood is rarely met with in any other condition than exhibiting its structural formation, I shall confine myself to its durability when in an unpainted condition, and, as in most cases, where it is kept dry. As the durability of timber in many warm climates is partly due to the resistance it affords to insects of various kinds which prey upon it, it is not unlikely that the resin this Cedar possesses and retains, is offensive to these agents of destruction. Even in this country we are not exempt from the destructive effects of such enemies. Beech chairs quickly fall a prey to them. The Deodar is as durable as the Cedar of Lebanon, if, indeed, both are not the same species.

It is much to be regretted that the patriarchal trees of Lebanon, like their compeers in California, are far from numerous; in fact, the reports of recent travellers place the number very low indeed, a gradual diminution having been going on for centuries. Some authorities dating back to 1550, make the number of large old trees only twenty-eight, and subsequent enumerators have made them gradually less, until in 1818 there were only seven, which appears to be the number of the principal group at the present day; but one or two solitary specimens have been discovered on other parts of the mountain, enabling some travellers to make as many as ten trees of the largest size. Around these a smaller crop is springing up of the sizes often met with in English pleasure grounds, but the whole area of the once-important forest of Lebanon is reported to be narrowed into a space not larger than that of many private pleasure grounds, and the number of trees of all sizes (excepting, perhaps, the smaller seedlings, of which there is abundance), is said not to exceed 500. An American traveller, Dr. Thompson, counted 443. This number seems small, and all writers concur in lamenting the decreasing numbers of this interesting forest, and leaving us little hopes of the tree's reappearing in any great number, unless under those conditions of artificial culture or protection which deprive it of most of its interest.

The trees, it would appear, are growing on those rocky shelves which form an important feature in all mountain countries, where the decomposed rock mingled with vegetable matter has formed a soil adapted for most of the fruits and plants that are useful to man, and where the Coniferae thrive particularly well.

It is also probable that a similar position marks the spot where the Himalayan Deodars are found, only the latter are at an altitude of several thousands of feet above the Lebanon trees, and what is more strange still, as before stated, so much farther inland, consequently beyond the reach of whatever influences the winds might acquire in passing over an expanse of salt water. A certain amount of hardness would seem to be required for both situations; possibly frost may be more felt on the Himalayas than on Lebanon, but the latter has quite as tempestuous a position, and it has its frosts and deep snows as well. It would be a great loss if the small remnants of the ancient forests of the Israelitish kings were entirely destroyed, and it is to be hoped that the same Society which is now prosecuting its researches amongst the antiquities of the Holy City, and its neighbourhood, will also take charge of the few remaining trees. It is painful to reflect that their number is really much less than could be found within a few miles of London.

In speaking of Cedar wood there is often great confusion, for it not unfrequently happens that some Cypress is confounded with it, to which nothing can well present a stronger contrast, and the reader will at once point to the small slips of a rather soft wood forming the black-lead pencils of everyday use. These Cedar pencils, as they are called, are said to be made from a soft kind of Cypress imported from Florida, while the kind of Cedar met with under the name of pencil Cedar, used in furniture-making for the lining of drawers and wardrobes, is from Bermuda. There is every reason to believe that not only the roof of the Holy Temple was composed of Cedar of Lebanon, but also the roofs of similar buildings devoted to heathen deities. The Temple of Diana at Ephesus was said to be of this tree and to have lasted four hundred years; while another, dedicated to Apollo, built with Cedar obtained from the African coast, was said to be quite as old. In Hindoo usages the durability of Cedar wood was equally appreciated, as it was used to contain the remains of the most renowned men, and for other purposes where endurance was required.

In this country, who can say that any other tree exceeds the Cedar in beauty when the specimen is good? and there are many such in England, the valley of the Thames containing many noble trees, as at Chiswick, Sion, and higher up, while even in the far north of Scotland it is growing with as much vigour as the native Fir; and as many of the oldest specimens in this country exhibit no signs of constitutional debility, it may be placed on the same footing in that respect as our native trees, which is certainly not the case with many Conifers of more recent introduction. Those, therefore, who wish to plant a given space, as an avenue, or even to plant a single tree as a memorial, I would recommend to select young, well-rooted plants of the Cedar of Lebanon that have not been in pots, and if the site be favourable the result need not be feared. I would certainly advise the Cedar of Lebanon in preference to the Deodar, for if the latter is not the same, it is inferior to it; but I expect that eventually they will be both regarded as one.—J. ROBSON.

TRICOLOR PELARGONIUMS BREAKING.

Your correspondent, "PERSIST," asks, "How long a time elapses before a Pelargonium will break, or show signs of variegation, if bred from a green Zonal?" This depends upon how much tricolor blood there is in the seedling plant. Some seedlings will show signs of variegation in a very young state, others will continue growing for several years without the slightest symptoms of variegation appearing, and afterwards throw out variegated sports. I have found that green seedlings bred from variegated parents, if crossed again with the pollen from variegated varieties, will generally produce a large percentage of green seedlings slightly tinged and striped with variegation on the cotyledons or seed leaves. Some of these will show symptoms of variegation very early, by streaks of red, white, &c., appearing on their stems, and spots and blotches of variegation on some of their leaves. After the plants have fully developed from five to seven leaves, the green portions of the leaves should be gradually pinched away, this will allow the variegation to predominate and assume the mastery over the green portion of the plant. Much, however, will depend on the skill of the person having the care of the plant, as to whether it will survive after its green portions are taken away. If the plant has not a strong, vigorous constitution, the green portions of its leaves must be very gradually pinched away, otherwise the plant will become weakly, and ultimately die altogether. When the seedlings are small, and the proportion of

variegation is too great, it is often necessary to pinch away portions of the variegation in order to allow the plant to gain strength by allowing the green portion to take the lead for a short time. This may be easily checked by the means mentioned above, and the growth of the plant regulated to the greatest nicety, if its condition be properly studied, and a due amount of watchfulness be bestowed on it.

I know of no branch of floriculture more interesting than this, nor anything approaching the interest one feels in it after becoming acquainted with the subject.

The next question asked by your correspondent is, "If a Tricolor Pelargonium is bred from a golden variety, what will the seedling be?—will it be golden, and afterwards break?" No favourable results can be expected, or if expected such are seldom realised. The progeny in this case would be so weak that little or no hope could be entertained of their ever surviving more than a few days or weeks after their appearance above the surface of the soil. They have, generally, very little chlorophyll in the cotyledons or seed leaves, and are, consequently, unable to bear the light. A golden variety should, therefore, never be selected as the female parent.

The third question, "If seedlings raised from a Bicolor will be bicolored?" may be answered in a similar way to the above. Bicolors do not make good seed-bearing parents for the same reason, unless they are very strong growers, and have not much yellow in the leaf.

The best of all parents to select, is a good green horseshoe kind, with a good habit, and having the zone clearly defined and deeply stamped on the leaf.—J. WILLS.

INTERIM REPORT TO THE COUNCIL OF THE ROYAL HORTICULTURAL SOCIETY.

BY THE SUB-COMMITTEE APPOINTED TO INQUIRE INTO THE ADULTERATION OF SEEDS.

1. IN accordance with your instructions, your Committee have taken steps to ascertain whether there is any just foundation for the representations which have been made to the Council regarding the unsatisfactory state of the seed trade and the bad quality of much of the seed sold to the public.

2. It was represented to the Council that, as the business of seedmen is at present conducted, the purchaser of seeds frequently receives neither the kind nor the quality of the seeds he pays for, and that against this he has no remedy except a doubtful and expensive lawsuit after the mischief has been done.

3. It was also urged that, unlike most other kinds of adulteration or deception in the quality of goods, the injury done in the case of seeds does not terminate with the use of the article purchased, but entails, in addition, the loss of the rent of the ground on which the seed may be sown, and of the labour expended upon it in preparing the soil and tending the crop—not to speak of the disappointment of the reasonable expectations of the cultivator.

4. Having no means of compelling parties to give evidence, your Committee's investigation into the alleged adulteration, mixing, or deterioration of seeds has necessarily been confined to making inquiries of those who have the means of knowledge, and on whose statements they could rely.

5. From information so acquired, they believe that the public suffers more or less from the neglect and malpractices of dealers in seeds in at least the following ways:—

(1.) Generally by seeds being kept too long and being sold after they have lost their vitality.

This is the most injurious of all the causes of depreciation; for it applies equally to the honest and dishonest trader. In adulteration, the evil must be done with the intent to defraud. Here there may be no intention to defraud, but mere neglect or want of judgment may be as injurious to the purchaser as if there were.

(2.) By the addition of bad seed to good, and mixing old and new.

(3.) By the addition of seed whose vitality has been killed.

This is done in the case of varieties of peculiar excellence, when the supply is insufficient to meet the demand. Killed seed of a cheap kind, similar in appearance to that of a dear kind, is added to increase the quantity without affecting the quality. In this kind of adulteration the purchaser is only deceived in the quantity. What comes up at all, comes true, and the character of the dealer for supplying a true article is maintained.

(4.) By manipulating and doctoring the seed so as to make bad seed look like good, as by dying bad Clover seed, sulphur-smoking bad grass seed, oil-dressing bad Turnip seed, &c.

6. Your Committee have been unable to ascertain to what extent these different practices are carried on; but they have reason to think it must be considerable. One of their informants was able, from personal knowledge, to instance one individual whose principal business consisted in destroying the vitality of cheap seeds for the purpose of mixing with sound seed of greater value; and they have reason to believe that this is by no means a solitary case. They are told also that

large numbers of people obtain a livelihood by the manufacture of bad into apparently good Clover seed.

7. Your Committee next endeavoured to ascertain how far the various causes, above-mentioned, actually affect the productiveness of seeds sold in the market. They have not at present made any tests with the view of determining how far seeds sold as of special quality or kind come true. Their experiments have, in the first instance, been directed solely to the vitality of seeds; and to that alone the present report applies. In a future report they may deal with the quality of the kinds of seeds sold, as well as some other collateral points.

8. In entering on the inquiry as to vitality, your Committee attempted to obtain a test for guessing at the age of seed by the percentage which comes up; but this they found impossible, so much depending on the original quality, and the care with which the seed has been afterwards stored. They made, however, some trials of Turnip seed with this intent; and it may not be without interest to mention that, in them, they found the percentage which came up from home-grown good seed one year old to be 80, three years old 43, seven years old 32, and the older the seed the lower the rate of germination.

9. It would have been beyond the means at the disposal of your Committee to test even a small sample of the goods of all the seedsmen and nurserymen in London; but by going only to the wholesale dealers, from whom the retail dealers of course chiefly obtain their supplies, they thought they could arrive at a fair estimate of the general character of the seeds sold throughout the country. It appears from Dr. Hogg's "Horticultural Directory" that there are twenty wholesale dealers in London. From each of these (with the exception of two, who were accidentally omitted), the Committee purchased samples of five of our commonest garden vegetables (Cauliflower, Broccoli, Carrots, and White and Yellow Turnips)—care being taken to prevent the purpose for which they were wanted being known. The samples were numbered, and the names of the dealers from whom they were got were kept secret. 100 seeds of each package were tested by the Society's officers at Chiswick, and a like sample separately by one of the Members of the Committee, and the number of seeds which came up were counted. In addition to this test, in a number of instances, especially where, before sowing, the appearance of the seeds was not good, they were mechanically tested by crushing and microscopic examination; and that test was found to correspond with the result of the trial by sowing. The test by floating was also tried, but, found of no value, in the kinds of seeds specified.

10. The results of sowing, as shown by the average of both trials (which, it is right to say, in general corresponded very closely), were as follows:—

Out of the eighteen packages of 100 Cauliflower seeds, the following numbers respectively came up—viz., 86, 70, 66, 60, 56, 54, 54, 52, 51, 51, 50, 44, 44, 44, 39, 36, 24.

Out of the eighteen packages of 100 Broccoli seeds, the following numbers respectively came up—viz., 86, 83, 70, 68, 65, 62, 60, 59, 56, 55, 50, 46, 42, 42, 39, 35.

Out of the eighteen packages of 100 Carrot seeds, the following were the numbers which came up—viz., 61, 56, 54, 48, 47, 45, 44, 43, 41, 38, 38, 37, 37, 35, 33, 30, 19, 11.

Out of the eighteen packages of 100 White Turnip seeds, the following numbers respectively came up—viz., 98, 95, 93, 87, 87, 83, 82, 71, 70, 68, 68, 66, 65, 64, 62, 60, 58, 57.

Out of the eighteen packages of 100 Yellow Turnip seeds, the following numbers respectively came up—viz., 95, 84, 79, 79, 78, 77, 72, 72, 67, 66, 63, 64, 62, 58, 55, 55, 44, 28.

11. It should be added that the quality of different kinds of seeds obtained from the same tradesman was not always uniform, all good or all bad; the Cauliflower would sometimes be inferior and the Turnip superior, and so on; but on the whole, a good position in one kind was generally accompanied by a good position in all. It is also to be observed that the general percentage is less on some seeds than others—a difference probably due to the greater care required in harvesting them, and in the case of Carrots, to the difficulty in separating the good seed from the bad.

12. In seeking for a remedy for the evil, your Committee recognised the existence of two distinct elements in it, each requiring different treatment:—1, the actual adulteration of seeds; and, 2, the mere keeping them too long and selling them when too old.

13. Actual adulteration is entitled to no mercy. It is a deliberate and intentional fraud, in the suppression of which the trade is as much interested as the general public, and ought to be suppressed by the strong hand of the law in the same way as any other fraud.

14. It is different with the selling of old seed. The seeds produced in different years, like different vintages, vary in their quality and in their power of retaining their vitality. It thus sometimes happens that two-year old seed is better than one-year-old. There is thus a special difficulty in dealing with it; but it is clear that the public are entitled to get what they pay for; and if it is necessary, to secure this, that the dealer should test the quality of his seeds each year, it is his duty to do so.

15. It seems a right and proper thing that Government should bestow some pains in protecting the very large numbers of ignorant and uneducated people who have to purchase seeds. In Prussia, Sachverständer, or, as we should call them, experts, are appointed by Government, whose duty it is, for a certain fee, to test the quality of the seeds of such merchants as apply to them, and to publish the

results; and in some districts (Saxony and Wurtemberg, for example) there are officials, paid by the Government or district, whose business it is to look after the culture of fruit trees and to give gratuitous advice to all who apply to them for it.

16. But, independently of the action of Government, your Committee are disposed to think that the Council of the Royal Horticultural Society might itself do much to encourage the sale of good seeds, if not to prevent the sale of bad. How it can most effectually exert its influence for this purpose, is a question on which the Council might probably obtain useful suggestions from the respectable members of the seed trade; and your Committee recommend that a number of them be invited to meet the Council and give their views as to the best steps to be taken to remedy the evil.

WHORTLEBERRIES.

I HAVE seen it provokingly announced that Whortleberries were selling in Providence at 10 cents a quart, and we learn that the price in Woonsocket is only 5c. Happy Woonsocketites, to have a supply of berries at that price! Here (Newport), they are to be had, but not for a dime, be the market never so well supplied. Why we are forced to pay more than our neighbours for the fruits that grow wild on every hillside and bit of waste land I know not. I only know that the cry is, as usual,

"Huckleberries is skerse," and I believe they are always so in the estimation of those who deal in the article. The complaint is as "old as the hills," and was familiar to the ears of Rose Standish and other early American housewives.

Whortleberries are peculiarly an American institution. The Germans have what they call heidel beere, or heathberry, from the good old Anglo-Saxon heortberg or hastyberry—at best but an indifferent fruit. The English have the Bilberry or Blea-berry, a stunted shrub but a foot high—

"Where fires thou find'st unkind, and hearths unswept,
There pinch the maids as blue as Bilberry."

And the Scotch have the Cowberry—long the badge of the Macleods—a small, sour, and puckery fruit that would make one exclaim, as did the Yankee who tried the green Persimmon, "Mister, am I whistling, or what am I doing?" In our own country, well known to be the real home of the Whortleberry, we have half a dozen varieties, all known to consumers as Whortleberries. They are gathered at this season in endless quantities, and should be dog cheap.

There was one man who made a marked impression on my mind in early life, and stands out in bold relief as I review the scenes of my childhood—Naaman Gardner. Berries, which he always maintained were "skerse," were his staple of trade in the summer. In his day—the halcyon days of those who were fond of Whortleberries—they sold for three or four cents per quart, milk measure at that, at which price every one could afford to indulge in them freely. We boys bought by retail, and for a cent obtained a large beach clam shell full—about half a pint, which were turned into the crowns of our straw hats till we could make way with the fruit. When berries were out of season he filled his baskets with other commodities—wild Grapes, Berberries, Sweet and Sour Apples, and "yarbs"—taking with him at the same time a bundle of brooms or a basket or two to sell, the latter of his own make. They were strong white oak baskets, with only one fault—the handle was never in the centre; and this man at length claimed that they were put on one side intentionally, just as the Vermonter, who had one long and one short leg, said he was made so on purpose to mow on a side hill. I could relate other peculiarities, but I have already rambled far enough from my subject—the price of Whortleberries.

A farmer in Narragansett once told me that he could gather Whortleberries enough on the farm he hired to pay the rent; and from what I saw there I have no doubt but that he could easily have done so; and yet that fellow, with a miserable lot of cow frames, tried to keep the appearance of a dairy farm in a barren and "sparse" section, where nought would grow but wiregrass, Whortleberries, and Alders, with a sprinkling of black snakes, woodchucks, and skunks. In a short time he played out, and I have always associated him and others like him with the steady increase in the price of berries. They have neglected to gather the bountiful stores of the swamps and wild lands; and middle men—the sharpers—have monopolized the market, substituted wine for milk measure, run up prices, and played the dickens generally with the Whortleberry trade. Think of Whortleberries selling at 16c. a quart in the middle of August, or rather think of being asked that price for them, for they don't sell—much.

Whortleberries are good in any form but dried, a process that deprives them of every good quality, leaving us only the shrivelled skin and seeds; in pies, tarts, flapjacks, johnny cakes, &c., but to my mind the "hollow"—a good old-fashioned Whortleberry hollow—is without a peer in the world. Some cooks make a batter, then stir in the berries and boil the whole together—making a heavy, doughy mass, and altogether a waste of most excellent materials. With others it is the custom to line a deep dish with puff paste, pour in the berries, cover with a thin paste, bake and serve with sauce—a good, palatable dish, but not the hollow of our forefathers, which must be made of Potato crust—for the reason that it is far more tender than puff paste—rolled out thin and spread over a pudding cloth; then pour in the berries, gather up the side of the crust and pinch it together—not, however, in a way that will make a lump of dough at that point—tie the bag and boil till done. When ready for the table, serve with sauce, but let it be sauce, not a little warm sugar and water thickened, nor a lump of butter and sugar rubbed together till snowy white, as firm as wax and as dry as table salt. These are makeshifts. But here is a recipe worth to any housekeeper a year's subscription to the Journal:—A cup of sugar, and a little less than half the quantity of butter, worked together till white and smooth; add a wine-glass of good wine, flavour with nutmeg,

and stir in boiling milk till the whole is of the consistency of thick cream. Send it to the table, and stir it well when served. Test the above, and my word for it, you will ever after use it for puddings of all kinds requiring sauce.—*AQUIDNUCK (in Providence Journal.)*

FAILURES IN BOTTOM-HEATING.

We have received several complaints with regard to pipes laid in open rubble, and laid in a chamber covered with slate, that though the pipes are made hot, the heat does not rise into the bed above. This reminds us of a case that came under our own practice in Cucumber-growing. We have hardly ever been more successful than in a common brick pit, all above the ground; the walls formed of single brick on bed, with 9-inch piers to give strength, and the bricks laid in cement, as all the heating was done with mounds of rank fermenting dung outside the pit, turned at times, and kept banked up nearly to the wall plate. The bottom of the pit inside, for nearly half the depth, was roughly shod or chambered with stones, brickbats, and furnace clinkers, and covered over so as to have a thin layer of pebbles and clean-washed rough gravel on the surface to receive the soil for the Cucumbers. It was hoped that as the outside wall became hot, the heat would so circulate amid the openings of this loose bottom, as to give plenty of bottom heat. The closeness of the walls prevented all steam entering, and the walls at the top gave out enough of heat to keep up the top temperature, and when we wanted a moister atmosphere we had merely to sprinkle the walls with a little water, but in the winter that was only necessary in very bright weather. Nothing could have answered better for a time than the above plan for securing bottom heat; but presently, do what we could, though the walls outside were quite hot, we could not make the soil in the middle of the bed as warm as we wished. We racked our brains for some time to little purpose, when by degrees we reflected that confined air is one of the worst conductors of heat, and the air in our rough brickbat chamber was as confined as it well could be. Luckily we had a rough open flue, or space rather, along the middle of the bottom of our pit, and by putting down a drain tile at each end, the one end of the tile resting above the opening, and the other end standing a few inches above the soil, and furnished with a plug, we found that the earth in the centre soon began to be heated; and to make me sure of the air being put in motion, we had a metal pipe at each end outside, communicating with the open bottom, and by opening these pipes a little at times, we found the heat from the sides circulate all the way beneath the bed, so that the centre of the bed of earth was nearly as warm as the sides. Now we mention this because a fact is often more convincing than precept. If a heated chamber does not heat the bed above it, a little air admitted in two or three places near the bottom of the chamber will give a circulation to the confined air, and cause it to heat readily the bed placed over it.

Another cause of want of success when the pipes are covered with rubble, is having the pipes at too great a depth from the bed to be heated. True, heat will rise, and will not be lost; but the deeper the pipes the more liable will the heat be to be diffused longitudinally instead of vertically, and the more likely, too, will be the air round the pipes to be confined and still, unless some means have been taken, as above, to keep the air in motion.

When hot-water pipes are used for bottom heat, it is well to use no fermenting material in addition to the pipes. A says he put a 2-foot bed of cocoa-nut refuse over his pipes, and in a few weeks he could secure no heat for his pit, though the pipes were warm. B used dung and leaves for a similar bed, and as soon as the heat from them declined, he derived no benefit from his pipes; he said they were warm, but the heat would not rise. This was partly owing to the air about the pipes being confined, but it was chiefly owing to the material next the pipes becoming gummy and caked, and the such such dry material neither cold nor hot will easily pass. For a plunging bed above such heated medium, we do not recommend sand or fine ashes as being as good as anything else, and these no deeper than is necessary.

When a bed is supplied with pipes for bottom heat, it is often necessary for distinct purpose to have the plants nearer the glass, and then a raised bed of fermenting material may be necessary. A genial heat is thus given at once, but if that is to be continued with the help of the pipes, then it will be necessary to have the means, by tubes, &c., of pouring water

down among the pipes, and the vapour rising will prevent the material next the pipes becoming dry, and thus the heat will be conducted through the mass. Heat will rise through a fair thickness even of cocoa-nut fibre, if the fibre is moist. It will not rise through any bulk of it if it is dry, and the same fact will hold good as respects dry tan, dry leaves, dry dung, or even very dry soil. We do not at present know of any better modes for removing a disappointment that is not seldom felt.

Heat often fails in common hotbeds of fermenting material long before the material is exhausted, not so much, as in the above cases, from obstacles being presented to the free conduction of heat, as from the material heating itself dry, or becoming so solid that air cannot penetrate to keep up a slow decomposition. The giving of water through tubes, &c., and air along with the water, will cause a fresh fermentation in the one case, and merely forking over a bed when it has become solid from the mere air thus given and covered in, will insure a gentle heat for a month or two, when none would have been obtained from a bed in its solid settled-down condition. The materials for yielding heat were there, but air as the great decomposer could not reach them, to act as flame to the fuel. Much skill is required to make up a common hotbed so as to give the most lasting and continuous heat. If built too loosely the air will dry it, and thus arrest decomposition and the heat it produces. If too close, air is kept out, and thus decomposition is arrested. The turning-over lets the air in, and then it acts like a bellows to a sluggish fire, giving out more heat, of course, at the expense of the fuel—the decomposition of the fermenting material.—R. F.

NOTES AND GLEANINGS.

At the meeting of the Fruit Committee of the Royal Horticultural Society on Tuesday next, there will be an interesting EXHIBITION OF GRAPES, the following prizes being offered—viz.:—A. For the best dish of Grapes, consisting of six bunches of any variety, grown in the open air against a wall, without any protection whatever, £2; £1. These prizes are offered by the Rev. George Kemp. B. For the best collection of any description of Grapes, except Muscats, one bunch of each, £3; £2. C. Ditto White Muscat Grapes, one bunch of each sort, £3; £2. It is not imperative that the Grapes shown in this class should be grown by the exhibitor, the object of the Committee being to obtain specimens of all the varieties of White Muscat Grapes that are grown in different parts of the country, for comparison. D. For the best dish of Muscat Hamburgh Grapes, £1; 10s. In a season like the present, the out-of-door Grapes are, no doubt, unusually fine. It is, therefore, a happy thought of Mr. Kemp to have offered the prizes on this occasion.

—MR. DAVID THOMSON, so favourably known to all horticulturists as Lady Mary C. Nesbit Hamilton's gardener at Archerfield, will soon leave that place to occupy a similar position at the still more extensive establishment of the Duke of Buccleuch, at Drumlanrig Castle, in Dumfriesshire.

POMOLOGICAL GLEANINGS.

D'AGEN FIG.—This is the latest variety of Fig with which we are acquainted. It comes into use after all the others are past, and is very valuable on that account. In the large and fine collection of Figs in the Royal Horticultural Society's garden, Chiswick, we have to-day observed in pots two handsome plants of this variety quite laden with beautiful green healthy fruit, which has just commenced to ripen. The plants being placed in a sufficient heat, the fruit will continue to ripen successively from this time up to Christmas. There are many varieties from which occasionally there may be a few straggling late fruits gathered (the fag-end of the crop), but they are not to be depended upon, and they are generally of but indifferent quality. This variety, then, which only commences bearing at the present season, is a decided acquisition. The fruit is above medium size, roundish turbinate, very regularly formed, and very handsome. Skin deep green, covered with a fine bloom, cracking when ripe in shallow white lines. Eye small, generally closed. Flesh deep red, solid, firm, and rich. Should be in every collection.

—DEUX SŒURS PEAR.—When ripe and mixed with Marie Louise, this variety may easily be mistaken for the latter. It is a very handsome fruit, the colour of the skin pale yellow,

with a little russet exactly like Marie Louise. It is, however, rather more uneven under the skin, and fuller towards the stalk, and the stalk itself is thick and fleshy, instead of slender like Marie Louise. The flesh is slightly granular at times, but buttery and melting, with an exceedingly sweet and almost honied taste. The tree is a good bearer, and forms a neat pyramid on the Quince.

The name Deux Sœurs (Two Sisters), it is said, was given to this through the fruit generally growing on the trees in pairs, which it certainly does—a very marked characteristic.

—THE REV. C. P. PEACH, of Appleton-le-Street, writes:—"I wish you could see some Apples and Pears I had from BUSH TREES this year—1300 Seedles from a two-year-old bush, and the most wonderfully fine Easter Beurré, Beurré Diel, and Van Mons Léon le Clerc. I had a tree, too, of Pike's Pearmain Apple planted twelve years ago, which is now about 9 feet high and 8 feet through, which bore from sixteen to eighteen pecks. I do not think there was any 3 inches on the tree down to the very ground without a fruit on it."

—RIVERS'S EARLY NONPAREIL.—Along with some specimens of the old Golden Pippin Mr. Rivers has sent us a few examples of what he calls "our Early Nonpareil." He thus designates it by way of distinction from the Early Nonpareil, or Hicks's Faucy, as some call it. It is a perfectly different Apple, and is supposed by Mr. Rivers to be the old Haute Bonté of the French, which Miller in his Dictionary says is often sold

in the streets for the Nonpareil. It is quite distinct from that variety, and is one of unusual excellence. The shape is not unlike that of the Nonpareil, and the colour, in the highly coloured specimens, is of a bright aurora glow. It is a larger and a handsomer Apple than the old Nonpareil.

—WE have received some Red Currants grown by Mr. Twells, a mechanic at Letchurch, Derbyshire. They are fully ripe, and quite of an average size and excellence. Their peculiarity is that they are part of the second crop produced by the same bushes this year. A dish was gathered on the 11th inst.

BEDDING-OUT AT CLIVEDEN.

ONE of the prettiest examples of what may be done in the way of bedding with succulent plants alone, such as Sedums, Echeverias, &c., that we ever recollect having seen, is a small bed planted by Mr. Fleming at Cliveden this season, representing the monogram of Harriet Duchess of Sutherland. We have tried by the aid of the accompanying engraving to give some idea of how this has been carried out. It is, however, one of those things that require to be seen to be understood and thoroughly appreciated. It is impossible to show in a sketch of a bed of this sort the different forms of the various plants, their different hues, &c., which are so neatly and happily blended in this little gem. It is planted thus:—

The H is formed with small plants of *Arabis lucida variegata*; the two S's and the largest circles with *Echeveria secunda*

glauca; the two small circles with *Sempervivum hirtum*. The eight centre plants are beautiful specimens of *Echeveria*

metallica, which show up exceedingly well, and the circles are joined to the *Echeveria* by cross bands of *Sempervivum*

hirtum. In the centre angle, front side, are three nice plants of *Gasteria verrucosa*, and in the back angles small plants of some species of *Mesembryanthemum*. The front edging is the beautiful *Sempervivum californicum*, and the back edging *Sedum carneum variegatum*. These being the leading hues in the bed, the intervening spaces are all filled with a deep mossy carpet of, first, *Sedum glaucum*, which has a pretty silvery appearance, and, second, a deep green variety of *Sedum*; and *Sedum denticulatum rubrum* filling up the corners.

WORK FOR THE WEEK.

KITCHEN GARDEN.

As soon as we hear of the thermometer having fallen 3° or 4° below freezing, we must have mats ready for covering up with. Some gardeners, however, are unwilling to expose their best mats yet, for fear of these becoming saturated with wet, and thus being rendered of less service when there is need for them. *Cauliflowers*, pull up a number of those that are fit or nearly fit for use, and lay them in by the heels in some moist earth in a dry shed or outhouse. It is as yet too soon to put them in the cellar. Choose a dry, well-sheltered border, dung and dig it as well as you can, and the first mild day plant it all over in patches with good *Cauliflower* plants, ready to be sheltered when necessary with hand-glasses. *Cabbages*, if any failures have happened in the rows already planted, the spaces should now be filled up with the strongest plants you have on hand; nothing looks worse in winter than to see gaps here and there in any rows or crops of plants. Plant out *Endive* and *Lettuce* for spring use. If planted on the sloping sides of wide ridges they will withstand the winter better, damp being quite as destructive as frost. Take the precaution of securing a quantity either in pits or in frames, or have the means of protection in readiness. Remove the leaves from *Rhubarb* and *Sea-kale* intended for early forcing, and keep a look-out for slugs and weeds, both of which will be troublesome after these rains.

FRUIT GARDEN.

Prepare for planting all kinds of fruit trees by putting the ground in good order for the different kinds. The sooner the trees are planted the better, as they will then make firmer roots before winter. In all cases, but more especially in the case of cold, stiff soils, it is advisable to plant on hillocks a foot or 18 inches higher than the surrounding surface. The trees will not grow so fast in consequence, but will require more attention to mulching in summer, but they will form short-jointed, well-ripened, fruitful wood, which is the best preventive of canker, gum, &c., and will save resorting to much root-pruning. Pruning may now be commenced, beginning first with the Currants; the Gooseberries and Raspberries may follow, this will clear a considerable space of ground to be dug in fine weather. Apple and Pear trees should follow, and then look over trees against walls, and cut away useless laterals and late growths on the Peach trees; indeed, any shoot that will not be wanted in spring, had better be cut out at once to make more room for the others, and let in the sun and air to ripen the bearing wood for next year; the leaves of Peach trees are of little use after this time, and they do much harm by shading the wood.

FLOWER GARDEN.

If there is one thing more than another which contributes to the high keeping of this department, it is finely-kept and perfectly smooth turf; in truth, it is impossible to produce a harmonious whole if the turf which surrounds the groups of flowers is not in every respect perfect, and for this reason at the present season it is advisable to replace every foot of bad turf that can be found in any part of the grounds. This is the best season to lay turf, except under large trees, and in such situations it is better to delay it until spring, or the constant drip consequent on the rains of winter would materially injure it. However, fine turf will not please if it is not level, and for a lawn to be beautiful it must be level, smooth, and perfectly clean. At this season, also, the edgings which surround the walks and borders, should be adjusted to one regular height. Level turf and edgings, combined with good walks, will give a garden a highly finished appearance, even though there is not a flower in it. Herbaceous borders may now be regulated, reducing the large plants considerably, and preferring rather to leave the outsides than the centres of the plants. Where the plants have not been regulated for some years it will be best to take them all up, manure and trench the border, and replant them properly.

GREENHOUSE AND CONSERVATORY.

Those who have not the advantage of cold turf pits will have to crowd the greenhouse on the approach of frost. However small a place may be, there ought to be some contrivance for sheltering half-hardy greenhouse plants late in the autumn, without crowding them into houses thus early. The Chrysanthemums and Pelargoniums ought now to occupy the best places here, and more hardy plants will be much better in pits where rain and frost could be kept from them till the Chrysanthemums are nearly over, and room for them in-doors can be made. Some of the late Chrysanthemums can be retarded by placing them under a north wall. Strong plants only should thus be treated, and rough sticks should be placed against the wall over them to support mats, which should be put over them in frosty nights. Pelargoniums with sweet-scented leaves are very useful for mixing in bouquets in winter. *Jasminum grandiflorum* makes an excellent climber in the conservatory, but is seldom to be met with as such. *J. stellatum*, *ligustrifolium*, *birsutum*, with the varieties of *J. sambac*, and some others, are good plants for forcing to decorate rooms. For this purpose their climbing habit should be checked by under-potting, and by pinching-off the points of the shoots when the parts are young; they will then form bushy heads and flower more freely.

STOVE.

Phajus grandifolius, or *Bletia Tankervillei* as it was once called, is an excellent plant to force in winter, and should now be removed to the forcing pit where a brisk bottom heat of from 80° to 90° can be kept up. *Euphorbia jacquiniæflora* is unwilling to submit to much forcing at this time, but if checked now by being kept rather dry for a month or six weeks, it will flower a month earlier than its usual time. Old plants of *Justicia speciosa* and *Eranthemum pulchellum* always flower earlier than young ones, they should be ready for the conservatory at the same time with the early Chrysanthemums. *Nematanthus longipes* is a curious winter-flowering stove plant of the easiest culture, and well suited for the drawing-room or conservatory when in flower, as is also *Centradenia rosea*, which is a gem in its way. This also flowers in winter and early in the spring. *Achimenes picta* seeds freely, and, no doubt, will produce crosses; it is well worth having on that account, as well as for the beauty of its flowers and the singularity of its foliage.

PITS.

The forcing pits should now be in full operation to keep up a stock of flowering plants for the rooms and conservatory through the winter. All hardy and half-hardy plants brought in for forcing should have at first a temperature of from 50° to 60°, to be increased to 75°, when more advanced; but as many plants will not bear such heat, and others will not do much good without a high temperature there should be two distinct pits, or divisions at least, for this purpose. In large establishments many plants are forced in the stoves and earlyinery. With a large stock of Chinese Azaleas, some of them may be had in flower from Christmas till the end of May; the first lot should now be brought into a heat of 50° or even 60°. The double Roman Narcissus is the first of the forced bulbs, and when it has been potted early it will now stand a heat of 60°. Hyacinths that have also been potted before the middle of August will now endure a good heat and bloom early without at all injuring the bulbs, whereas late-potted bulbs, though they will flower well enough if forced early, are of no use afterwards. —W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

AFTER much rain we have had two or three rather fine days to finish the week. Took the opportunity to fill up blanks among Cabbages and Lettices, which the insatiable grubs made like Feins. As to these depredators, after the plants are put in the earth, we know of no certain remedy, except hand-picking. Before planting, if we had known they would have been so numerous we would have sprinkled tar water, and even tar itself in small quantities on the ground, and turned the soil frequently. We hope we have caught the most of them now.

Celery.—Tied and earthed it up in the dry afternoons, confining our work to cleaning and tying the later beds, though if fine dry weather come we shall not hesitate to earth up the main crops, as the objections will not apply that we have urged in the case of early Celery. Hitherto we have only done little spaces at a time, according as we judged we should want it,

earthing-up at once from twenty-one to twenty-eight days before we wanted the Celery for the table. Sometimes we have had it very good after fourteen days, but our medium time in general is twenty-one days. After the middle of this month all the evaporation from the leaves will not make the roots very dry, as dews and rains to a great extent neutralise the force of the sun's rays.

Dwarf Kidney Beans.—Those fully exposed, owing to the rains, and a little frost a few mornings ago, are now looking worse. Even those protected will not do much more good. Those in a pit where a little heat can be given will produce by the time the protected ones are gone, and before the soaking cold rains; those sown in pots in the open air were placed in the same pit, where a little artificial heat can be given.

Cucumbers.—The young plants in the pit are bearing too profusely, and have been thinned of their fruit, and a number of small ones cut off, as we would rather have a quantity a month hence than so many now, and being well aware that if young plants bear profusely at first, they have less strength left to produce fruit in the dark days. Where such cold things as Cucumbers are desired all the winter, we recommend a steep roof, and, therefore, plenty of light, and the command of plenty of heating power. We know what it is to manage them in flat-roofed pits and frames, and we have seen and helped the good old gardeners to have fruit in winter in dung frames and pits, but the constant care and attention required in stirring the soil, washing the glass, careful air-giving, and securely protecting, would be a good lesson to many of our spruce young gardeners now. With all the benefits that hot water has afforded us, it has rather lessened the strict attention to minutiae that could alone secure success in the old-fashioned modes.

Earth Pits.—Several inquiries about these prompt us to say, that they are most generally useful when the bottom of the pit is higher, rather than lower, than the surrounding ground, as then it is easy to guard against extra damp. A good width is from 5 to 6 feet; and for low plants 9 inches in front, and from 15 to 18 inches at back, are very good heights. In the simplest form have these walls of earth from 15 to 18 inches in width, and if covered with a layer of turf they will last for many years. When turf cannot be had, the walls sloping outwards may be beaten smooth, then covered over with tar the thickness of a shilling, and gravel or rough ashes beaten into it. This, if done and well hardened before frost, will last many years. The best coverings for such a pit are glass sashes, wooden covers, covers made with asphalt, waterproofed cloth and canvas to roll up, neatly-made straw covers, and hurdles thatched with evergreens. The first named will be the best, and in value they will come in as named. All those that keep out wet as well as cold will be the most valued and the most useful. Where rats, rabbits, and other vermin can be excluded, such pits are very useful. Where these animals abound they will clear the pits in frosty weather, when those plants outside will be left alone. We have had a score of fine Cauliflowers spoilt in a night at Christmas, and what was most vexing the intruders are nothing in proportion to what they destroyed. Otherwise these pits are great auxiliaries in winter and spring.

FRUIT DEPARTMENT.

See what was stated last week, and a few weeks previously, as to fruit, planting, replanting, and root-pruning. The great drawback is, that there is generally such a difficulty in getting work done at the proper time. The struggle is too often how to go on without allowing anything materially to suffer. We have known cases where work had to be found every season to keep the usual number of men employed; but now the generality of gardeners have to try as much as possible to avoid extra work, as even without it they find they cannot have their regular work as forward as they would wish. We have no objection to having plenty in hand, and difficulties staring us in the face, provided we can look forward to the time when we shall master the work, instead of allowing the work to master us. We know it is depressing to use every energy, and yet never see daylight beyond, and such a condition of things is apt to cause a man to do his work merely as a matter of duty, and not as a matter of pleasure and enthusiasm. Even in our limited observation, we know not a few instances where a little extra help, instead of lessening help when most needed, would make all the difference between the enthusiast, who will look at difficulties only to resolve to surmount them, and the mere six-o'clock man who does a certain amount of work in so many hours, and in time becomes careless of the work that cannot be overcome. Without a little enthusiasm nothing great has ever yet been done; but employers who are apt to grumble

as "MAUD" pleasantly tells us, are also apt to forget that they may have had much to do in toning down the enthusiast into a mere plodder, a worker without heart and mind in the work.

In our first orchard house, there being besides Grapes not yet thoroughly ripened, lots of Figs that require a little more heat in this weather, we have in dull wet days put a fire into our iron stove. We have also replaced the glass ventilators at the apex of the roof, which we had removed, and put gauze in their place to keep the wasps out. But for retarding the Peaches as much as possible, the Grapes and Figs would have been ripe in such a season as this. The Figs now coming in are chiefly the second crop. We are often asked many questions about such composite houses—that is, having Grapes, Peaches, Plums, Figs, &c., under one roof, and without divisions. It is best to have only one kind in one house; but then that would not suit nine-tenths of our readers, and very good returns can be had from all, if sudden checks are not given to one kind of fruit, to meet some desired condition in another kind of fruit. For instance, in this first orchard house, could it have been convenient to use the Peaches as they ripened, without changing the little forcing they were receiving from sun heat, then the Grapes would have progressed also without a check so as to perfect their growth and ripening. The means, however, which we took by slight shading, and giving all the air possible night and day, to retard the Peaches for a few weeks later, somewhat checked the free swelling of the Grapes. Then, also, it is well, in all such mixed houses, where many kinds of fruit are grown, to make one kind, be it Peach, Plum, Cherry, or Vine, the principal object, and make the others subsidiary to it. Thus we made Peaches and Nectarines the chief objects in this house, and though we shall have good gatherings of Grapes, they would have been finer and earlier, could we have given them the full benefit of the sun in such a fine summer. This would have been of importance even in the case of late Grapes, as these will keep better that were ripened in September, than those ripened much later.

Strawberries in pots have needed no watering of late, and if the rains continue it will be as well to turn the pots on their sides. A dusting of soot over the soil in the pots will also do them good. Our plants are not so strong as usual; we had such a difficulty in securing runners, and feared at one time that we should lose the established plants. The pots are becoming so full of roots, that, provided we have a fortnight of fair weather, we shall have little fear of the plants not fruiting very fairly when fruit is wanted. We will have all our outside beds cleaned and mulched as soon as we can, and such work we never like to do except when the weather is fine and dry.

We have pruned and washed the front of our early Peach house, so that we might fill the front with bedding plants. The back, not so forward, we will leave for a few more days; and cleaning the walls and washing the trees can be done in a wet day. Transplanted a tree to fill a small vacancy, as it is a pity to have a foot unoccupied under glass.

ORNAMENTAL DEPARTMENT.

Potted a number of stove plants. Gave less water to those intended to flower in winter. The fine showy Euphorbias, &c., should now be rather dry. Water now chiefly in the morning, that the houses may be dry before night. We shall ere long prune-in climbers on the rafters, to give all the light possible in winter.

We took our cuttings later than usual this season, and a great number of Scarlet Pelargoniums being out of doors in boxes, and just beginning to root, but apt to be tender from so much rain, we have had them transferred to the Peach house, where they will be safe from rains and slight frosts, which we may now expect. Our first vinery will also be filled with flowering plants, which we cannot yet take into the conservatory. The Verbenas, Heliotropes, &c., that were put in pots as cuttings in the cold pit, have on the whole done well, and where they had double sashes they gave scarcely any trouble, as with air at night they needed no further attention. All the most backward of these have been placed in another pit, where a little bottom heat can be given them, not so much that they require it, as because we need the cold pit for inserting our Calceolaria cuttings, which we hope to do about the middle of the month. We would as soon do this at the end of the month, only we may have a frost, but we hope not for a month, and if not, there will be a fine late display in the flower garden. The moving even of these cuttings does them good, as we can run a pointed stick over the surface, and perform any little cleaning that is necessary. We have a large number of cuttings of bedding Pelargoniums, &c., put in thickly in small

pots, and the moving of so many other things will give us more room to turn them over, pick off any bad leaf, and give them a little more room in the old frames, in which they now stand. By leaving few leaves on such cuttings, and putting them in very thickly, we winter a large number in very little space, and in ordinary seasons in autumn we are rarely troubled with a damped leaf; but now we see there are some leaves going, owing to the dull, damp weather, and our sashes being anything but perfect, so that they will be all the better of being picked over, and having the benefit of full exposure in fine sunny days, as even variegated Pelargoniums are juicy enough for the cuttings to stand that for short intervals, even before they are rooted. If the cuttings are large, they will stand all the sun they are now likely to have; if small, they will feel the full exposure to the sun more.

We have taken off a lot of the white-leaved *Centaurea*, though rather late, but we have taken large cuttings with firm bottoms close to the old stem, and cleared the bottoms nicely for an inch or so, that there may be no risk of damping. Part of these in small pots we have put in a bed with a little bottom heat, and part on an open shelf in the vinery. The bottoms being so firm, we have little doubt the cuttings will escape the damping, so apt to befall small soft cuttings at this season. It is best to take cuttings in July and August, but ours were not large and firm enough. We took up our plants from the beds last year, and, treating them as then described, we did not lose one, but they require much room in winter.—R. F.

COVENT GARDEN MARKET.—OCTOBER 11.

THE market in respect to home-grown produce exhibits but little variation from our last report, a fair amount of business being done in articles of general request. Among imports from abroad we may now include new Oranges from the south of Spain. The report from the Potato markets is not so satisfactory, a large quantity proving very inferior when taken up.

TRADE CATALOGUES RECEIVED.

Charles Turner, Royal Nurseries, Slough.—*Select List of Pelargoniums, Auriculas, Carnations, Pinks, Fieeetes, Camellias, Arabas, &c.*

Godwin & Sons, Ashbourne, Derbyshire, and Edmonton, London.—*Catalogue of Roses, &c.*

Julien Monnier, à la Pyramide, près Angers (Maine-et-Loire).—*Wholesale Priced Catalogue of Ornamental Trees and Shrubs, Fruit Trees, &c., 1868-69.*

TO CORRESPONDENTS.

N.B.—Many questions must remain unanswered until next week.

ODONTOGLOSSUM GRANDE.—In the last Floral Committee Report, it is stated that an *Odontoglossum grande* from the Society's gardens with six flowers in great perfection, received a certificate. It should have been with sixty-two flowers in great perfection.

Books (T. S. S. H.).—If you send twenty postage stamps with your

address and order Kesne's "In-door Gardening," you will have it sent free by post. It contains directions for the culture of potted plants under glass. You must send another leaf and flower in a box. The others are smashed. (*Try Green*).—"The Pine-Apple Mannal;" you can have it free by post from our office if you enclose thirty-two postage stamps.

THORNS DYING AFTER BUDDING (*C. Ellis*).—We are quite at a loss to account for your Thorns dying after budding, and after the fresh buds had pushed vigorously. Perhaps you cut away the old parts of the trees rather soon, and this paralysed root action; but that could scarcely be the case when the fresh buds grew so vigorously.

CUCUMBER FOR WINTER (*A Subscriber*).—There is nothing better than the old Lord Kenyon, or Lion House, or some of its smooth-skinned varieties. Volunteer is a very good kind, a little longer, but not so long as the Telegraph or Manchester kinds. We would say Lord Kenyon or Lion House. Take care your flue does not become too hot, or allow gases to escape.

GRAPES SHANKING AND RED (*J. W. F.*).—With Vines that have been bearing forty years, it would not be advisable to raise the roots and replant, except in rare cases. We think that as the Vines are healthy, make good wood, and bear well, but have shanked bunches, we should be inclined to try what raising the gravel path would do, placing good soil instead, and sinking a drain in front deeper than the bottom of the border, using fire heat now to harden the wood. If you resolve to make a fresh border and raise the Vine roots and replant, we would recommend a concrete bottom, 30 inches from the top, and the bottom sloping well outwards, a drain 18 inches deeper in front, three-inch drain tiles laid across at every 8 feet, and 8 inches of open rubble round and over them. Have upright pipes communicating with the cross pipes and open rubble, and the upright pipes furnished with plugs to allow hot air to circulate through the border and keep cold air out. But for having the old Vines we would rather plant strong young Vines. There is much labour involved in taking up the roots of old Vines carefully and keeping them properly wrapped up before replanting.

PEGGING DOWN ROSES—STOPPING SIDE SHOOTS (*E. F. W.*).—"The side shoots from the strong shoots, stopped six weeks ago, may be left till spring, and then be shortened to the first plump eye in sound wood. The more you cut a strong-growing Rose the stronger and more blind will it become. I do not peg-down Roses. I prefer them upright, as more manageable. It is difficult to weed beds of pegged-down Roses; moreover, you cannot go among them. Why not try growing them espalier fashion? A few Roses will make more show when pegged-down than in an upright position. Roses that do not break well at the eyes, and cast their flowers at the tops of the shoots, are suited to pegging-down and to espalier training."—*W. F. RADCLIFFE.*"

ROSES FOR CONTRAST (*M. R.*).—"These as standards in three colours would look well:—Charles Lefebvre, Gloire de Dijon, and Senateur Vaisse; or Prince Camille de Rohan, Céline Forestier, or Triomphe de Rennes, and Madame Victor Verdier. For white you cannot have a more excellent and beautiful Rose than Baronne de Maynard. It has been covered with flowers throughout the season, and without intermission, and is still flowering abundantly. Comtesse de Chabillant, Madame Videt, and Madame Rivers do best as dwarfs on the Manetti stock. The last two are the most beautiful and perfect light Roses known, but very delicate and difficult to keep in health. Buy Marguerite de St. Amand and Caroline de Sansal instead of these. Marie Baumann is here, but not yet proven. Mr. Keynes speaks very highly of it. Buy Alfred Colomb and Antoine Ducher and you will be right. Due de Cazes or Charles Lefebvre would make an excellent climber for your south-east wall. Maurice Bernardin is a most superior crimson Rose."—*W. F. RADCLIFFE.*"

FORCING VINES AND PEACH TREES FOR FRUITING IN MAY (*Old Sub.*).—To have Grapes ripe in May, the Vines should be started gently in the beginning of December. If now in full leaf shorten the shoots and keep the border rather dry, so as to prune in November. Peach trees to produce in the end of May should be started slowly at Christmas.

HEATING A VINEY BY A STOVE (*W. Mash*).—It is impossible by any one mode to obtain all advantages. All stoves to be economical must have rather small fireboxes, and therefore want frequent attention, and at least should be cleaned out every morning where fuel that will cake or leave a clinker is used. A brick stove, 30 inches square outside measure, and from 42 to 48 inches in height, with a firebox 12 inches square, and 15 inches deep, would keep the frost out of a house 20 feet long and 10 feet wide, and gently force the Vines. The top of the stove had better have two plates of iron, one to rest on the bricks, bedded in mortar, and to be covered with sand, leaving a ledge of brick outside, into which the plate fits, and then another plate all over with a sand joint between. The small chimney should go out at one side, 6 inches below the plate, extend 18 inches horizontally, and then pass perpendicularly through the roof. If the stove is placed near the front of the house, the fuel-feeding door and the ashpit door might be outside. If it is necessary to feed the stove inside of the house, it will have to be emptied carefully every morning, damping ashes, &c., previously to prevent dust. Such a stove must have the draught regulated by the ashpit door, which, therefore, must fit closely, but we did not expect you would be able to obtain such doors absolutely air-tight, nor is that required. With all improvements for heating a small house, there is no plan so economical as a brick or even an iron stove. There are few of the latter, however, that would enable you to dispense with lighting, as the fire space is not large enough to hold enough of fuel, and then if it did it would require some experience so to manage it as not to have too much heat, and so to regulate the air that enough be given, and no more, to secure slow combustion, as, if not enough reaches the fuel, it will go out from want of oxygen, which is as necessary to keep fuel burning as to enable us to breathe. If the freedom from relighting your fire cannot be secured, then we would recommend a small conical boiler, to be fed from the top, and only the best broken coke, or the best coal that leaves nothing but a little ash, used. All caking coal will leave clinkers. Your crop of Grapes is fair, but not heavy. To have larger bunches, you had better begin afresh next season, and take up a fresh rod from each Vine. Give that rod the second season more room, and take fewer bunches. You will thus have no difficulty in obtaining larger bunches, but otherwise you will have more trouble. It will also be advisable to allow more growth. With Vines spurred 2 feet apart up the roof, we have no hopes that you will do much with Vines against the back wall. It would be better to have shelves there for various plants before the Vines covered the roof.

HIPPOMANE RHAMNOIDES (*J. S. H.*).—This is the Sea Buckthorn, or Sallow Thorn, as it is sometimes called. In a sandy soil and sheltered situation it might succeed and ripen its berries in the midland counties; but not unless care be taken to have male and female plants growing together. The female flowers are produced on separate bushes from those which produce the male flowers.

AMARYLLIS BELLADONNA (*H. T.*).—Your Belladonna Lilies have done very well indeed; but we have seen quite as good specimens when the bulbs were well established.

NECTARINE LEAVES UNHEALTHY (*A. S. A.*).—The leaves have been attacked with red spider, and we think thrips has also been present, but we are not sure. If many of the leaves are green they might be well washed with soft-soap water. If as bad as the specimens sent, we would pull them all off, wash the part of the tree, the wall, &c., with warm soap-water—say at 140°, and when dry paint the wood with Gishurst compound, or clay and sulphur.

PEARS OF ASTRINGENT FLAVOUR (*A Subscriber, Norfolk*).—Many varieties of Pears have deteriorated both in flavour and appearance owing to the extreme heat and dryness of the summer and the autumn. This has been especially noticed on sandy soils like yours. Such deterioration would have been prevented by mulching the surface over the roots and occasional watering. Some varieties will endure much higher temperatures than others.

FORCING ROSES AND STRAWBERRIES IN COLD PITS (*A Subscriber*).—To keep Roses and Strawberries in a brick cold pit, they will do best with just enough of tree leaves to plunge them in, whilst the pots rest on the hard bottom. If you wish to force gradually, then a bed beneath them of fermenting material would be an advantage, and it does not in the least matter whether the bed is of sweetened dung below and leaves above, or all leaves, but it is of importance that the heat should not be strong at this season, not above 70°, and also that the Strawberry roots should not be encouraged to run through the hole in the pot into the leaves. It would be well to move the pots frequently, or set the pots on boards and slates when plunging them.

WINTERING BULBOUS PLANTS (*Idem*).—The Liliams will keep very well in the cold pit, and will need no water in winter if a few damp leaves be placed over the surface of the pit. The soil should not be wet, but it should not be dust dry. They would keep well in a cellar, or under the stage in a cool greenhouse, before they begin to push, when they must have light and water, and fresh surfacings with rich soil. The bulbs of the Tropicolum should be kept dryish before they begin to push. It is well to report them when in a dormant state, and place at once in the flowering-pot, and water as the roots advance. The *Valletta purpurea* will not need much water in winter, but it should not be dry, and the leaves should not wither. A cool greenhouse will suit it best.

INSECTS (*J. S. E., Dorking*).—"Your 'red daddy' was, doubtless, *Ophion luteum*, one of the Ichneumonidae; all the females of which family are furnished with a sting, but it is very weak, and used chiefly for depositing eggs, and very rarely as an instrument of defence."—*W.*

GARDENING CATECHISM (*E. S. B.*).—There is one in the "Finchley Manuals," but it only relates to cottagers' gardens; and there was one by the Rev. Mr. Edwards, but we believe it is out of print, and only relates to vegetable and fruit culture.

LARGE SUNFLOWER (*O. S. Round*).—Ten feet ten inches is a very great height for a Sunflower; and the flowers 10 inches in diameter, and the leaves 22 inches long, are large in proportion.

MASTERS' TROUBLES (*Nemo and Others*).—You all quite mistake "MAUI," all her banter and pokes are at the exceptional characters. She is the friend, not the enemy of the profession. You will see what she says ere long about "Gardeners' Troubles."

ADDRESS (*A. Z.*).—Messrs. Betham & Blackith, Cox and Hammond's Quay, Lower Thames Street.

TREATMENT OF ROSE CUTTINGS (*Rose*).—The cuttings put in six or seven weeks ago, and now struck, may be potted off singly into small pots, care being taken not to injure or break the roots. The pots should be well drained, and the compost may consist of two-thirds turfy sandy loam, and one-third leaf mould, or old well-decomposed manure, adding one-sixth of sharp sand, well incorporating the whole. After giving a gentle watering plunge the pots to the rim in coal ashes in a cold frame, and put up the lights, keeping them rather close for about a fortnight, and then well hardening off. The plants cannot have too much air, but protection should be given from frost and heavy rains by drawing on the lights, and in severe periods the protection of a mat or other covering should be afforded.

ARALIA JAPONICA CULTURE (*T. C.*).—It is a deciduous shrub, and requires to have the stems protected by a band of straw and hay, wrapped round them from the ground upwards. You may, if convenient, take up the plant, place it in a large pot, and winter it in a cool greenhouse. In summer the plant may be planted out, or the pot plunged in the ground, and in autumn be lifted. In this way it would give you greater satisfaction, as in cold districts it is liable to lose its side branches in winter when left out of doors. It is grown for its foliage; its flowers are produced in panicles, and are greenish.

PROPAGATING MAGNOLIAS (*Cornubia*).—As preparation by layers is inconvenient, you might succeed in striking cuttings of the ripened wood, taking the growing points after they become firm, cutting them across below a joint, and removing the leaf from that and the joint above. The cuttings should be inserted in pots singly in sandy loam, and with one or two joints in the soil, and the same number of joints above it, the surface of the soil being covered with about half an inch of silver sand. A gentle watering should be given, and the pots plunged to the rim in tan or sawdust over a hotbed of from 70° to 75°. If in a house, the cuttings ought to be covered with a glazed frame, or if the hotbed is in the open ground, the frame should be kept close and shaded from bright sun. No water should be given beyond a sprinkling occasionally to keep the soil and atmosphere moist. In about six weeks they will be rooted. The best times to put in the cuttings are September, and about the beginning of April.

PROPAGATING LAURELS, PRIVET, AND ARBOR-VITÆ (*An Inexperienced Amateur*).—Laurels and Privet are propagated by cuttings. The Laurel cuttings should have been put in some time ago, the end of September and beginning of October being best, but they will yet succeed. The

growth of the current year should be taken with a joint or two of the old wood, and should be cut across below the lowest joint, and the leaves removed half way up the cuttings, though that is not material. They are then to be inserted in a sheltered situation, making a trench as for planting Box, and placing the cuttings against the side of the trench, at about 3 inches apart, and so that they will be one-half or two-thirds of their length in the soil. The soil is then to be placed against them, and is to be made firm. The next row may then be put in at 6 inches distance from the last, and so on to the sixth row, when 2 feet must be allowed for an alley, so that you will have the cuttings in 4-foot beds, and six rows in a bed, with a narrow alley of 1 foot wide between the beds. Privet cuttings may be put in in the same way, but not until November, and it is not necessary to take them off with a portion of old wood; they should have only two or three joints above the soil, fully two-thirds of their length being covered. The shoots should be cut into lengths of 9 or 10 inches, and ought all to be of uniform length, or have their tops cut off. Arbor-Vitæ is best raised from seed, but cuttings of the current year's growth will strike if inserted in sandy soil in a cold frame. September is a good time. There is no cheap work on the subject you name.

STRAWBERRIES TOO DEEPLY PLANTED (*Idem*).—You may now take up the plants with good balls of earth, and plant them higher. They will not be injured to any great extent; indeed, if the operation be carefully performed it will not interfere with next year's crop.

PINE APPLE CULTURE (*R. F. Wheeler*).—Pine Apples may be grown cheaply and to pay, but you cannot do it without a house specially devoted to them, and we fear your prejudice against the present mode of Pine-growing will deter you from the undertaking. They are not worth growing if not grown well. Small inferior Pines are not worth eating. Read the "Pine Apple Manual," which you can have post free from our office for 2s. 8d.

SOWING LEUCADENDRON ARGENTEUM SEED (*Amateur*).—The seeds sent you are those of *Leucadendron argenteum*, the Silver tree of South Africa, an evergreen. The seeds should be sown in March in a compost of sandy peat and loam in pots well drained, covering with soil to a depth equal to the diameter of the seeds. Give a gentle watering, and plunge the pots in a hotbed of from 70° to 75°. When the plants are a few inches high they should be gradually hardened off, and removed to an airy greenhouse. When the pots are full of roots the plants should be shifted into others of larger size, using the same compost as before, and the soil should at all times be kept sufficiently moist. The plant succeeds well in an airy greenhouse.

GRIFFINIA HYACINTHINA NOT FLOWERING (*Idem*).—We can only account for your large bulb not flowering from your not ripening off the growth well, and the size of pot is perhaps too great. We would advise you not

to pot the bulb, but to let it be pot-bound, still keeping the drainage clear, and removing all offsets. Encourage the plant when it makes new leaves, by plentiful supplies of water and a moist atmosphere, and when a good growth has been obtained, and the foliage is firm, place the plant on a shelf in the stove, and in the full sun, giving no more water than enough to keep the leaves from flagging. Hardly any water will be needed from October to February; indeed, the bulb can hardly be kept too dry. This we think will give you flowers. It is a stove plant.

POTTING LILIUM GIGANTEUM (*Idem*).—In potting, the bulbs should be covered to the neck with soil. They are no better of being more deeply buried, nor of being left further out of the soil.

LISTS OF PEARS (*H. J. C.*).—For *pyramids* in North Hants—Jargonello, Doyenné d'Été, Baronne de Mello, Urbaniste, Louise Bonne de Jersey, Huyshe's Victoria, and Forelle. For the *west wall*—Louise Bonne de Jersey, Bergamot, Gansel's Late, Colmar d'Été, Alexandre Lambré, Beurré Superfin, and Thompson's. For *south wall*—Marie Louise, Fondante d'Automne, Winter Nelis, Beurre de Rance, Beurré Sterckmans, and Gansel's Bergamot. For *east wall*—Thompson's, Red Doyenné, Napoleon, Glou Morceau, Van Mons Léon Le Clerc, and Duchesse d'Angoulême.

NAMES OF FRUITS (*G. H. D.*).—Your Apples are—1, Yorkshire Greening; 2, Braddick's Nonpareil; 3, Autumn Pearmain; 4, White Nonpareil; 5, Nonpareil. The "g" in Margil is pronounced soft. (*J. D., Hford*).—1, Fall Pippin; 2, Beurré Blanc des Capucins; 3, Beurré Bosc; 4, Not known; 5, Grand Soleil; 6, Doyenné Blanc. (*M. C., London*).—Your Pear is Beurre d'Amanlis. (*W. H. C.*).—The seedling Apple is a very pretty and nicely-flavoured fruit. We do not recognise it as being the same as any known variety. (*J. Scott*).—The Apple is Cox's Orange Pippin, and we cannot identify the Pear. (*Someresh*).—Your Pear is evidently the Marie Louise.

NAMES OF PLANTS (*W. L.*).—1, *Cratægus punctata*; 2, *Cratægus purpurea alba*; 3, *Carya microcarpa*. (*P. D. M.*).—*Rhamnus latifolius*. (*M. H.*).—*Mentha rotundifolia* and *Aster dumosus*. (*E. C.*).—*Cinicalis flavens*, or *Notholana chrysophylla*. (*A New Subscriber*).—1, *Doodia caudata*; 2, *Lastrea Filix-mas cristata*; 3, *Pteris serrulata*; 4, *Doodia lunulata*; 5, *Asplenium Cyrtomium falcatum*. (*Discipulus Miteri*).—*Colea scandens* and *Aster amelloides* (*Agathia celestis*). (*C. G.*).—*Polystichum angulare*. (*C. P.*).—*Nicotiana undulata*. (*J. C.*).—1, *Acacia Drummondii*; 2, *Geuista canariensis*; 3, *Cytisus candicans*; 4, *Acacia armata*. (*Centurion*).—*Phycella lichenaria*. (*J. S.*).—1, *Gymnogramma chrysophylla* variety, very beautifully crested; 2, *Lastrea glabella*? 3, *Adiantum tenerum*; 4, *A. capillus-Veneris*. (*J. C. S.*).—1, *Asplenium auritum*; 2, *Hypolepis distans*; 3, *Doodia caudata*; 4, *Pellaea falcata*; 5, *Asplenium adiantum nigrum*; 6, *Pteris cretica*; 7, *Trichomanes pyxidifera*; 9, *Adiantum formosum*. (*M. D.*).—*Digitaria sanguinalis*.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the week ending October 13th.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

POULTRY AT THE YEAR'S DECLINE.

SHORTER days, colder nights, and damp weather call for the exercise of rather more attention towards our poultry. The quantity of food may be increased, and as the night is now nearly twelve hours long, care should be taken to give food just before roosting, and as soon as the birds are out in the morning.

Birds that have roosted out of doors ever since they were hatched, must now be brought in to roost in a house. Where there are many cocks, the young ones should be removed and shut up by themselves; or, if they are not wanted for stock, they should be fattened and killed.

Where space and conveniences permit, it is not too soon to begin thinking of the breeding pens, and while they are being put in order, scan the birds narrowly every day while they are feeding, that they may be easily recognised and caught when at roost at night. We are great enemies to the confusion and injury that ensue from *running fowls down* when they are wanted.

HOUDANS.

I HAVE reared an average of nine chicks from every sitting of thirteen eggs during the past two seasons. Some breeders would call this good luck, but in my opinion it is what any

person by the commonest attention might do with Houdans in the most limited space for rearing chickens.

I reared all my birds in a sandy yard for the first three days, giving chopped egg boiled hard, with bread crumb and lettuce, and after the third day their staple food was middlings and lettuce, with an occasional handful of shelled oats. With this food, supplied little and often, the birds grew with wonderful rapidity, and an aptitude to make flesh is a strong argument in favour of the breed for table purposes. Its flesh is delicate, tender, and nutritious. My Houdans hatched in April were fit to kill a month before Dorking chickens of the same age; but unlike other fowls, the hen birds are the most rapid of growth, and when only a few hours old may be distinguished from the cockerels by their superior vigour and larger crests.

As layers the Houdans will hold their own against any fowls with which I am acquainted; their eggs are large, of a fine rich flavour, and equal in weight to those laid by the famous Spanish.

The Houdans never sit, which is another strong argument in their favour, for cooping, and all its attendant trouble, are thus saved, and these birds after a couple of days' rest recommence laying, whereas "clacking hens" are the pest of the amateur's life.

The Houdan is gentle, very tame, and of a contented stay-at-home disposition; not at all a dainty feeder, and not addicted to scratching. As a proof that fanciers are becoming alive to the increasing popularity of Houdans, I may point to the fact that the late National Poultry Company at their sale obtained £8 10s. for their prize cock and hen, which was the highest

price paid for any two birds amongst the eight hundred sold.—
C. W. GEDNEY, *Sevenoaks, Kent.*

CHELMSFORD POULTRY SHOW.

THE fourth annual Exhibition of the Chelmsford and Essex Poultry and Pigeon Society was held in the Chelmsford Corn Exchange on the 6th and 7th inst.; but the Committee, which is one of the best working Committees we have met with, was in great difficulty in consequence of the unavoidable absence of Mr. Hewitt, who had promised to act as judge of poultry. Hearing, however, that Mr. W. B. Jeffries, of Ipswich, was in the town, no time was lost in waiting upon him, explaining the difficulty, and suggesting that he might withdraw his entries and judge in place of Mr. Hewitt, in connection with Mr. Tegtmeyer. This request he kindly acceded to, although it was very evident he was exhibiting by far the best Black Red Game Bantams in the Show. Three hundred and eighty-three entries, an increase of fifty-nine on last year, bore testimony to the growing popularity of the Show; and never had the quality of the birds on the whole been better.

Light Brahmas were in the ascendancy; there were twenty-one pens. The selling class was well filled, and contained some excellent birds, which were very soon claimed.

(From a Correspondent.)

THE classes were confined to chickens, and the pens consisted of one bird for cockerels and two for pullets in separate entries.

The *Dorkings* struck me as being somewhat small. A line bird of Dr. Campbell's was passed without notice, and I was not struck with the straightness of the tail of Mr. Parlett's first-prize coloured Dorking. The *Game* classes were good; but doubtless, like other parts of the Show, they would have been better filled if Manchester had held its Show at the usual time. A Brown Red chicken belonging to the Rev. F. Watson was a promising bird. *Cochins*, generally neither numerous nor good at this Show, were in fuller force than usual, and of better quality. The *Spanish* classes contained some good birds. *Brahmas*, both Light and Dark, were in great force, and good, particularly the cock birds. Amongst the *Hamburghs* were some fine birds, particularly Mr. Pittis's first-prize pullet. The French fowls were numerous, particularly the *Houdans*, which were very good.

Mr. J. K. Fowler exhibited a handsome bird "The Nigger," which obtained the first prize in the "Any other variety" class. It had no relationship to the Negro fowl, but appeared to be the body of a Japanese Silky enveloped in the feathers of a Frizzled fowl.

There were many entries of *Game Bantams* containing some fine birds, particularly Mr. Entwistle's third-prize Black Red, and Miss Marriage's Red Piles. A Golden Sebright cockerel, rich in colour and distinct in lacing, deservedly obtained the first prize in the class for Any other variety of Bantams. The Selling classes on the whole, were remarkably good.

Pigeons numbered sixty-seven pens, and formed a very good show, although many of them were not in feather.

One of the leading features of this show, and one which has been recommended so strongly by the Fowl Committee of the Society of Arts, is the classes for the best pair of dead chickens or Ducks, trussed as by poulterers, but not drawn. In these Mr. Dowsett's cross with the Brahma Pootra and the Dorking, twenty-two weeks old, weighing 16 lbs. 14 ozs., and another of the same age weighing 16 lbs. 9 ozs., had respectively the first and second prizes. In Ducks, the first-prize pair, twenty-one weeks old, weighed 11 lbs. 7 ozs.; the second, fourteen weeks old, weighed 10 lbs. 13 ozs.

The following is the prize list:—

DORKINGS (Coloured).—*Cockerels*.—First, F. Parlett, Great Baddow. Second, C. Turner, Great Baddow. Third, D. C. Campbell, Brentwood. Highly Commended, O. E. Cresswell, Hanworth. *Pullets*.—First, Viscount Turnour, Shillinglee. Second, F. Parlett. Third, D. C. Campbell.

DORKINGS (Any other variety).—*Cockerels*.—First, D. C. Campbell (White). Second, O. E. Cresswell. Highly Commended, I. Perry, Springfield (White). *Pullets*.—First, O. E. Cresswell. Second, C. Turner (Grey).

GAME (black-braced and other Reds).—*Cockerels*.—First, Rev. F. Watson, Messing. Second, F. R. Hall, Cambridge. Third, H. Lee, Appuldurcombe. *Pullets*.—First, S. Matthew, Stowmarket. Second, F. R. Hall. Third, H. Lee. Highly Commended, S. Matthew; D. Lane, Great Barr; H. Lee.

GAME (Any other variety).—*Cockerels*.—First, T. Dyson, Halifax. Second, R. B. Riley, Ovenden (Duckwing). Third, Rev. F. Watson (Pile). Highly Commended, W. Gray, Margaretting (Duckwing). Commended, W. Dale, Weston-super-Mare (Pie). *Pullets*.—First, S. Matthew (Duckwing). Second, W. Gray (Duckwing). Third, Rev. F. Watson (Pile).

COCHIN-CHINA (Buff).—*Cockerels*.—First, H. L. Ricketts, Banwell. Second, F. W. Rust, Hastings. Third, C. Sidwick, Ryddlesden. *Pullets*.—First, C. Sidwick. Second, F. W. Rust. Third, A. Barker, Roxwell.

COCHIN-CHINA (Any other variety).—*Cockerels*.—First and Third, H. Lingwood, Lucklesham (Partridge). Second, J. K. Fowler, Aylebury (Partridge). *Pullets*.—First and Second, J. K. Fowler, Wymston (Partridge). Third, D. Lane (White).

SPANISH.—*Cockerels*.—First, P. H. Jones, Fulham. Second, J. Walker, Wolverhampton. Third, F. Waller, Wood Green. *Pullets*.—First, P. H. Jones. Second, F. Waller. Third, H. Lingwood.

BRAHMA POOTRA (Dork).—*Cockerels*.—First, Second, and Highly Commended, Mrs. Burrell, Stoke Park, Ipswich. Third, H. P. Leech, Woodpat. *Pullets*.—First, J. K. Fowler. Second, H. P. Leech. Third, J. Tinkell, Islington.

BRAHMA POOTRA (Light).—*Cockerels*.—First and Second, H. M. Maynard, Holmewood, Hyde. Third, J. Pares, Postford. Highly Commended, H. Dowsett, Pleshey. Commended, F. Crook, Forest Hill. *Pullets*.—First, P. Crowley, Culverton House, Alton. Second, S. Felgate, Ipswich. Third, H. M. Maynard. Highly Commended, F. Crook. Commended, H. Dowsett; D. Couser, Erdington, Birmingham.

HAMPSHIRE (Gold or Silver-pencilled).—*Cockerels*.—First, F. Pittis, jun., Newport, Isle of Wight. Second, W. K. Tickner, Ipswich. Third, Viscountess Malden, Malden Hill, Hertford. *Pullets*.—First, F. Pittis, jun. Second, Viscountess Malden. Third, W. K. Tickner.

HAMBURG (Gold or Silver-spangled).—*Cockerels*.—First, J. Laming, Cowburn. Second, H. Lee. Third, Rev. F. Tearle, Gazeley Vicarage, Newmarket. *Pullets*.—First, H. Lee. Second, Rev. F. Tearle. Third, J. F. Lovelidge, Newark-on-Trent.

FRENCH VARIETIES.—*Cockerels*.—First, Col. Stuart Wortley, London. Second, Lady L. Charteris, Attleborough. Third, H. M. Maynard. Highly Commended, J. K. Fowler. *Pullets*.—First, Lady L. Charteris. Second, J. K. Fowler. Third, J. Lee, Romford.

ANY OTHER DISTINCT VARIETY.—*Cockerels*.—First, J. K. Fowler (Nigger). Second, F. Pittis, jun. (Andalusian). *Pullets*.—First, J. K. Fowler (Japanese Silkie). Second, F. Pittis, jun. (Andalusian).

GAME BANTAMS (Any variety).—*Cockerels*.—First, W. Adams, Ipswich. Second, Miss Marriage, Moulsham Lodge. Third, W. F. Entwistle (Black Red). Highly Commended, W. Dale, Weston-super-Mare (Black Red). *Pullets*.—First, Rev. E. S. Tiddeman. Second, Miss Marriage (Duckwing). Third, H. & S. Cooper, Walsall (Duckwing).

BANTAMS (Any other variety except Game).—*Cockerels*.—First, G. Manning, Springfield (Sebrights). Second, H. M. Maynard (Black). Commended, Rev. F. Tearle. *Pullets*.—First, E. Cambridge, Bristol (Black). Second, T. C. Harrison, Hull. Highly Commended, H. M. Maynard (Black); S. A. Wyllie, East Monksey (Japanese). Commended, Rev. F. Tearle.

DUCKS (Dromed).—First, Rev. G. Gilbert, Claxton. Second, D. Lane. Third, H. Dowsett. Highly Commended, F. Parlett. Commended, A. Hutley, Terling.

DUCKS (Aylesbury).—First and Third, J. K. Fowler. Second, E. Lawrence, South Weald.

DUCKS (Any other variety).—Prize, F. Pittis, jun. (East Indian).

GRESE.—First, J. K. Fowler. Second, S. H. Stott, Rochdale. Third, Mrs. E. Goodliffe (Toulouse). Highly Commended, Lady L. Charteris.

TRUCKEYS.—First, C. Carter, Billericay. Second, Mrs. Mayhew, Galleywood Hall. Third, H. H. Tippler, Roxwell. Highly Commended, S. H. Stott. R. Pigott, South Weald; G. R. Pearson, Witham Common.

SELLING CLASSES (Any variety).—*Cockerels*.—First, H. M. Maynard. Second, Rev. F. Watson (Game). Commended, D. C. Campbell (Coloured Dorking); Rev. E. S. Tiddeman (Game Bantam); J. Walker (Spanish); Viscount Turnour (Dorking); W. Tippler (Houdan); Lady L. Charteris (Houdan). *Pullets*.—First, J. R. Rodbard (Partridge Cochins). Second, D. C. Campbell (Coloured Dorking). *Ducks*.—First, J. Thompson, Writtle. Second, F. Parlett. Highly Commended, A. Hutley; H. Dowsett. Commended, Mr. E. Goodliffe.

PIGEONS.

CARRIERS.—First and Highly Commended, B. Fulton, Deptford. Second, H. M. Maynard. Commended, L. Wren, Lowestoft.

POUTERS.—First, P. H. Jones. Second, R. Fulton.

TUMBLERS.—First, R. Fulton. Second, P. H. Jones.

JEANETS.—First, H. M. Maynard. Second, H. Yardley, Birmingham.

FAVANTS.—First, H. Yardley. Second, P. H. Jones. Highly Commended, S. A. Wyllie; J. Lutkin, Farnham. Commended, H. M. Maynard.

BARBS.—First, H. M. Maynard. Second, P. H. Jones. Highly Commended, P. H. Jones; R. Fulton. Commended, H. Yardley.

TRUMPETERS.—First, H. Yardley. Second, E. Sheerman, Chelmsford.

ANY OTHER VARIETY.—First and Second, P. H. Jones. Highly Commended, H. M. Maynard (Archangel); H. Yardley. Commended, H. Yardley.

JURORS.—Mr. W. B. Tegtmeyer, of Muswell Hill, and Mr. Jeffries, of Ipswich.

STAVELEY POULTRY SHOW.

THE show of poultry held at Staveley, on the 29th of September, consisted of upwards of two hundred pens, and had the weather been favourable, would, no doubt, have been a complete success. Messrs. Chaloner, Jarvis, and Beldon were the principal winners, exhibiting really first-class birds in their several classes.

The following is the prize list:—

SPANISH.—First, E. Brown, Sheffield. Second, J. Thresh, Manchester. Highly Commended, Burch & Boulter, Sheffield. Commended, T. Rogers, Walsall.

DORKINGS.—First, Mrs. Arkwright, Etrall Hall. Second, Mrs. Hart, Allevsley. Highly Commended, C. Chaloner, Worsop.

HAMBURG (Golden-spangled).—First, H. Beldon, Bingley. Second, T. Hanson, Thwaites Bank. Highly Commended, T. Mason, Walsall.

HAMBURG (Silver-spangled).—First, H. Beldon. Second, C. Ontram, Sheffield. Highly Commended, Inghel & Boulter.

HAMBURG (Golden-pencilled).—First, H. Beldon. Second, Burch and Boulter.

HAMBURG (Silver-pencilled).—First, H. Beldon. Second, W. Bairstow, Feunell, Bingley. Highly Commended, T. Hanson.

ANY OTHER VARIETY.—First, H. Beldon. Second, E. Jarvis, Mansfield. Extra Second, W. H. Tomlinson, Newark. Highly Commended, W. H. Tomlinson.

GAME (Black and other Reds).—First and Cup, C. Chaloner. Second, B. Jarvis. Highly Commended, H. Warner, Loughborough.

GAME (Any other variety).—First, C. Chaloner. Second, R. Butcher, Crosswell. Highly Commended, Miss E. Crawford, Farnfield.

GAME BANTAMS (Black or other Reds).—First, C. Chaloner. Second, W. Adams, Ipswich.

GAME BANTAMS (Any other variety).—First, T. Evinson, Chesterfield. Second, Mason & Charlesworth, Chesterfield.

DUCKS.—First, F. E. Richardson, Uttrocter. Second, R. Hepplewhite, Staveley.

GULSE.—First, C. Chaloner. Second, B. Jarvis. Highly Commended, J. Crofts, Staveley.

SINGLE GAME COCK.—First and Cup, B. Jarvis. Second, C. Chaloner. Highly Commended, J. Fresh, Chatsworth.

SINGLE GAME BANTAM COCK.—First and Cup, C. Chaloner. Second, Mason & Charlesworth, Chesterfield. Highly Commended, Miss E. Crawford, Farnfield.

SELLING CLASS.—First, B. Jarvis. Second, H. Beldon. Highly Commended, T. Hanson. Commended, W. O. Quiball, Newark.

FARMYARD.—First, H. Beldon. Second, B. Jarvis. Highly Commended, B. Jarvis.

The prize for the winner of the largest number of prizes was taken by Mr. H. Beldon, Giltstock, Bingley.

The Judges were Mr. J. Crossland, jun., Wakefield, and Mr. E. Aykroyd, Bradford.

ELLESMERE POULTRY SHOW.

The entries for this Show, held on the 8th inst., proved more numerous than in previous years, and in the quality of the specimens there was a great improvement. The arrangements were good, a very commodious tent affording ample room to exhibit every pen to equal advantage. The day was one of those fair autumnal ones, so enjoyable for any Exhibition of this character, and the number of visitors was beyond the anticipations of the Committee.

Except in "the Selling Class," every competition was confined exclusively to birds of the current year. Of *Game* fowls, the display was unusually good, the whole being birds of high character, and shown very true to feather, though only a few years ago Game fowls were shown at the Ellesmere Meeting exclusively for their value as fighting birds, their only requirement at that time in the district, and without the slightest regard to uniformity of plumage. Now, on the contrary, the show of Game fowls evidences a most careful selection, and it is generally supposed not a few of the Ellesmere Game winners will figure highly in the prize lists of other Exhibitions.

The entry of *Dorkings* was exceedingly limited, and the *Cochins*, though few in number, were most of them of first-rate character. Many very good *Hamburghs* were shown, and a few pens of the *Pouter*s were really excellent. The *Brahmas* were as good as could be desired, the Hon. Miss Douglas Pennant showing such a pen as will be difficult to beat at any show. In the selling class a pen of very superior Partridge *Cochins* took the first prize, entered at the unusually low figure of 10s.; the three birds, of course, at such a price were gone directly. In the class for "Any other distinct variety" *Silver-spangled Pouter*s stood first, and *Green-Courts* second. A pen of most excellent fowls arrived for this class a considerable time after the prizes were awarded, as did some five or six other pens, leaving them entirely out of competition, equally to the annoyance of their owners and the Judge. It is very injudicious to entrust exhibition poultry to the last available train, as any little hitch on the line, or detention at the terminus, inevitably places them out of all chance of winning; whereas, if sent by a previous train, a similar delay of an hour or two admits, possibly, of being amended. The class for cottagers proved quite a failure, and will in future be discontinued.

GAME (Black-breasted Red).—First and Second, — Wilcox, Oswestry. Commended, E. Sadler, Whitechurch.

GAME (Brown-breasted Red).—Second, E. Shaw, Plas Wylldd.

GAME (Duckwing Grouse, White, and Pile).—First and Second, E. Sadler. Commended, J. Little, Chester; H. Crutchlow, Oswestry.

DORKINGS.—First, E. Shaw (Grey). Second, E. Williams, Heullys (White Rose-combed).

COCHINS—HINA.—First and Second, E. Tudman, Whitechurch (Partridge). Commended, G. Lamb, Compton (Partridge).

COCHINS—CHINA White or Buff.—First, R. Chase, Balsall Heath, Birmingham (White). Second, H. Yardley, Birmingham (Buff).

SPANISH.—First, J. Walker, Wolverhampton (Black). Second, H. Beldon, Giltstock (Black). Highly Commended, W. B. Etches, Woodhouse, Whitechurch; H. & S. Cooper, Walsall (Black).

HAMBURGERS (Silver or Gold pencilled).—First, H. Beldon (Pencilled). Second, J. R. Jessop, Hull (Golden-pencilled).

HAMBURGERS (Silver or Gold-spangled).—First, T. Blakeman, Tattenhall, Wolverhampton (Gold-spangled). Second, Ashton & Booth, Moffram (Silver-spangled). Highly Commended, T. May, Wolverhampton (Gold-spangled); J. Cooke, New Marton (Silver-spangled).

BRAHMA-FOOTY.—First, Hon. E. D. Pennant, Penrhyn Castle (Dark). Second, L. P. Biddulph, Condon. Highly Commended, Hon. E. D. Pennant (Dark). Commended, C. Layland, Morrisbrook, Warrington; E. Leech, Rochdale; W. B. Etches (Dark); J. Little, Chester.

ANY OTHER DISTINCT VARIETY.—First, H. Beldon (Pouter). Second, E. Williams (Crested Game). Highly Commended, C. Layland (French); Rev. A. Brooke, Ruyton-St-Town (Malay); J. M. Kivert, Lullox (Black Hamburg).

GAME BANTAMS.—First, A. Bury, Wrexham (Black Red). Second, W. Griffiths, Nantwich (Black Red). Highly Commended, J. Adams, jun., Walsall.

BANTAMS (Any other variety).—First, S. & R. Ashton. Second, T. C. Harrison.

TURKEYS.—First, E. Leech, Rochdale. Second, S. H. Stott, Rochdale.

GEES.—Prize, S. H. Stott.

DUCKS (Aylesbury).—First, S. H. Stott. Second, E. Leech.

DUCKS (Rouen).—First, E. Leech. Second, S. H. Stott.

SELLING CLASSES.—First, E. Tudman (Partridge *Cochins*). Second, W. B. Etches (Black Spanish). Third, H. Yardley. Highly Commended, H. Crutchlow, Oswestry (Black-breasted Game). Commended, J. M. Kivert (Black East Indian *Duckfins*); W. B. Etches (Golden-pencilled *Hamburghs*); R. G. Jebb, Ellesmere (Turkeys); H. Beldon; A. L. Evans, (Patagonian *Ducks*); E. Scaw (Ayle-bury).

LOCAL CLASSES.

GAME (Black-breasted).—First and Commended, H. Crutchlow. Second and Highly Commended, — Wilcox.

GAME PULLETS (Any colour).—First, — Wilcox (Black-breasted). Second, H. Crutchlow (Black-breasted Red). Commended, R. G. Jebb (Black-breasted Red).

DORKINGS.—First and Second, E. Shaw (Grey).

AMATEURS' PRIZES.—*Game Cock* (Any colour).—First, — Wilcox (Black-breasted Red). Second, E. Shaw (Black-breasted Red). Commended, — Wilcox (Black-breasted Red).

COTTAGERS' PRIZES.—*Any Distinct Breed.*—First, Withheld. Second, J. Eccles, Oswestry (Buff *Cochins*).

EXTRA.—Commended, P. Cooke, New Marton (Peacock).

Edward Hewitt, Esq., of Sparkbrook, Birmingham, was the Judge.

CHRISTCHURCH POULTRY SHOW, CANTERBURY, NEW ZEALAND.

THE first exhibition of poultry under the auspices of the newly formed Association took place August 1st in the New Town Hall, opening at 10 A.M. The number of entries was about 160, and comprised not only a large number, and variety of fowls, but many of superior merit; indeed, I may state they were quite equal to any I ever saw for sale at Stevens's, King Street, Covent Garden, a few years ago. All the arrangements had been carefully made, and the patronage of farmers and poultry fanciers on this occasion fairly claimed. Various prizes were offered, and a gold medal, value £5, was given by Mr. W. Wilson, nurseryman of this place, to the winner of the greatest number of prizes for poultry. From what I saw and judge for myself, I think the medal will fall probably into the hands of either Mr. J. Williams or Mr. A. M. Johnson, Curator, Acclimatisation Society. This gold medal has for some time been looked forward to with considerable interest by breeders, and the large attendance of visitors is a proof that the efforts of the Association are appreciated.

The experiment of holding a poultry show is quite new in Christchurch. I am informed that the number of available gentlemen competent to undertake the duties of judges was so limited as to greatly embarrass the management. This will account for a great deal of the grumbling which I heard, by exhibitors about their exhibits not being dealt fairly with by the censors. Possibly there may be some errors in judgment; however, being the first show they ought to be passed over; we must allow for these shortcomings.

I must not forget to mention the fine pen of Aylesbury *Ducks*. This part of the world seems to suit them; plenty of water-cresses, and whitebait for them when in season.

The exhibits of all sorts were exceptionally good, sufficiently so to have done credit, as already stated, to country shows at home, and older in competitions of the kind than Canterbury. The lots were required to be marked with their selling prices; a great number of the distinct breeds were sold at a very high price; in one or two instances a reasonable price being asked on the ticket, these birds of course were readily bought. Many persons, as well as myself, were not aware before to-day that the fancy of breeding poultry was carried on to such an extent here. It would not be a bad idea, if it were carried out, for the Acclimatisation Society and Poultry Association to amalgamate in Canterbury. We learn from the latest census taken, that Canterbury is already at the head of the list as regards the number of poultry bred in the provinces of New Zealand. According to the returns, this province possesses 161,882 head of poultry; Otago, 148,042; Auckland, 115,222, and so on; Taranaki or New Plymouth, 12,807.

Subjoined is the prize list; the closeness of the contest in some of the classes will be seen.

DORKINGS (Silver-Gray).—Prize, Potts.

DORKINGS (Coloured).—First, Bende. Second, Johnson.

GAME (Black-breasted Red).—First and Second, Rees. Highly Commended, Haskett.

GAME (Brown-breasted Red).—First, Fulton. Second, Boswell.

GAME (Duckwings).—Prize, Paredy.

GAME (Any other variety).—First, Andrews (Sydney Blue). Second, Mrs. Chudley (Blue Umb).

SINGLE GAME COCK (Any variety).—Prize, Haskett.

SPANISH.—First, Clark. Second, Gould.

COCHINS (Buff).—First, Chegweiden. Second, Mrs. Hornbrook. Highly Commended, Mrs. Hornbrook.

HAMBURGERS (Golden-pencilled).—Highly Commended, Russell.

HAMBURGERS (Golden-spangled).—First, Cole. Second, Donaldson. Highly Commended, Sneed.

HAMBURGERS (Silver-pencilled).—First, Donaldson. Second, Todd.

TOULANS (Silver-spangled).—Prize, Miss Gime.

FRENCH FOWLS (Crested Game).—First, Reeves. Second, Haywood.

MALAYS.—Highly Commended, Truynne.

PARTRIDGE.—First, Price. Second, Bays. Highly Commended, Laney. **GAME BANTAMS.**—First, Daire. Second, Williams (Black-breasted Red).

ANY OTHER VARIETY.—First, Walker. Second, Williams.

TURKEYS (Black).—Prize, Potts.

TURKEYS (White).—Prize, Adams. Highly Commended, Wilson.

GEES.—I do not recollect a wind any exhibited, we have abundance of them in the provinces, probably their absence is owing to this being our breeding season for them.

DUCKS (Aylesbury).—First, Johnson. Second, Wright. Highly Commended, Foster.

DUCKS (Rouen).—First, Gould. Second, Tapperrill. Highly Commended, Price.

ANY OTHER VARIETY.—Prize, Tubman.

I noticed a pen with a cock and two hen Pheasants in it from the Acclimatisation Society's Garden.

PIGEONS. — *Tumblers*. — Highly Commended, Anderson. *Jacobins*. — Prize, Williams. *Fantails*. — Prize, Miss Orme. Second, See. *Any other Variety*. — Prize, Williams.

N.B. — The Fantails were very beautiful, and attracted much notice. I think "WILTSHIRE RECTOR" would have been pleased to have seen them.

CANARIES. — *Cock*. — Prize, Clark. Highly Commended, Anderson. *Hen*. — Prize, Williams. Highly Commended, Ness.

N.B. — I can safely state that the Canaries were not up to the mark, notwithstanding the owners ticketed a very high figure on the cages; I think the highest priced one was £5. We have a great many choice and good birds amongst us, and I hope they will be better represented another time.

RABBITS (French). — Prize, Howell. *Any other variety*. — Prize, Foster. Highly Commended, Evans (Double Lop-ear).

— WILLIAM SWALE.

SOME NOTES ON PIGEONS.

PREVIOUS to my settlement in good Old England, I had the pleasure of visiting a portion of Asia Minor, European Turkey, Spain, Italy, Austria, Egypt, Belgium, France, and the United States. In every town one of my first inquiries was, "Are there any Pigeon dealers here?" And whether there were or not, I made out what sort of interesting specimens there were, and now from my observations give my conclusions.

In every one of the named countries existed once, and in most yet exist, the common sorts of half-bred Pigeons, of several colours. In the warmest countries, as in the case of the wild birds also, the Pigeons are most improved; for example, there are in Africa specimens of all sorts, and of all the distinct varieties exhibited in England. I observed, in general, that wherever cultivation or importation introduced the moderate and short-beaked varieties, the long-beaked sorts have disappeared gradually, and I believe I am correct in saying, that the same is the case in this country. So far as I am informed, once the principal breed was the worthy Carrier, in its several degrees, and the most beautiful Almond Tumbler, and nearly every fancier kept some form of the Carrier race. The introduction of the several short-beaked varieties has limited the Carrier fancy considerably, which I am very sorry to see, as I consider the English Carrier ought always to be preserved, as a contrast to the modern introductions. The principal reason of this apparent transformation, I believe to be public opinion, and this is also the conclusion from my inquiries in other countries. I say public opinion, because the general public, including modern fanciers, at sight appreciate a compact, short-beaked Pigeon, rather than a long-beaked one, and anyone can be convinced of this by a little attention to the remarks of the non-amateur visitors to the large Pigeon shows.

The only long-beaked varieties some of the general public appreciate, are the Pouters, the Fantails, the double-capped Trumpeters, &c., possessing some remarkable and pleasing attraction; and is not the Carrier most remarkable? I say decidedly it is; but we cannot prevent the general public, and especially ladies, from saying, "Oh! what unsightly, deformed heads and sore eyes these birds have. Are they well, poor creatures?" Although there is something remarkable and pleasant in the Pouter, Fantail, Trumpeter, &c., they do not approach the short-beaked varieties in public estimation even in England, where the latter are of comparatively modern introduction; but in countries where there are plenty, and such specimens as England has not seen yet, the long-beaked varieties have disappeared, or if any, are in the loft of some old lady or gentleman, like my uncle, who kept Runts, and large Trumpeters, whose progeny he had cooked by passing through them a long iron rod. They had to be turned by this rod over a charcoal fire, saturating them constantly with butter, and powdering them with ground biscuit till ready for the table, and I assure you they were infinitely superior to any which had been made into a pie.

The Carriers, Pouters, Fantails, Trumpeters, Runts, &c., are, of course, well known, and of great perfection in this country, so they need no comment from me. I pass, therefore, to the moderate-sized and short-beaked varieties. There are in this country Archangels, Nuns, Magpies, Swallows, Jacobins, &c., perfection, also of the short-beaked kinds there are perfect specimens of Almonds, of course, Owls, and Barbs, but unfortunately not of Turbits. I must say that I have not yet seen a well-formed and good-coloured Turbit, such as I met with on the Continent, where the black is as good as a good black Barb's, the red a deep warm red, and the yellow a fine deep

orange yellow, all shining naturally, as if they were varnished, instead of the generally faded dead-looking colours I see on their feathers in England. To my surprise, instead of persevering to improve this most important property, breeders have given their attention to breeding clear-thighed birds, which should be quite a secondary consideration. The eye, also, of the Turbits in this country is quite insignificant; the good continental Turbits have the lash round the eye of a most remarkable buff colour, contrasting most beautifully with the black eye, and increasing its apparent size.

In looking at the most interesting "new variety" class in our large shows, I always think of the answer I received from a great German new-variety breeder for the English market. I asked what is the origin of the Ice Pigeon, the Fairy, the Satin Swallow, and the like? The answer—"I mingle together in my loft a dozen of each of the following breeds: Hyacinths, Swallows, and Spots, of different colours, and Archangels; cocks of the two breeds, and hens of the other two, so that I may be sure of having crosses, and I obtain more new varieties than I can find names for!" And who can deny that nearly all the different new varieties have one and the same character? Certainly there are some with beautiful plumage, such as the Satin Swallow, but the variety from which it has taken half of its name, the Satinette is admitted to be the new variety which has revolutionised the fancy. As a proof, a reference to this Journal, from 1863 to 1866, will be sufficient to show that the Satinettes have done what no other variety ever did—in fact, they have tired the judges awarding them prizes, to such an extent that one judge said he must give the turn to others for encouragement. I never yet heard any fancier or observer say that he had seen anything prettier in the Pigeon tribe, and I never expected meeting with anything approaching them anywhere, till I saw this breed, which is a production of Africa, and my opinion most decidedly has been verified in England. The Satinettes possess as great perfection of plumage as any of the known new varieties, if not a superiority in that respect, with as exquisite and compact a form of head as the Owl, including the frill. They are Grouse-muffed, and the most remarkable of their properties are the tail feathers, which are of similar colour to those of the blue Owls, only darker, and at the extremity of each feather there is a white spot as large as a shilling, which is the admiration and puzzle of every fancier, as they are the only known variety possessing this beautiful peculiarity.—A FOREIGNER.

UNITING BEES.

In the case of late and weak swarms of bees, instead of waiting till the autumn, and driving and uniting them to other stocks, as directed in "Bee-keeping for the Many," would it do equally well to proceed in the same way on the evening of the day they swarm by knocking them out on the ground at sunset, and setting the stock they came from, or some other, over them—in short, proceeding in the same way as when uniting stocks in the autumn?

In putting a nadir under a hive, should it be permanently left there, or removed in the winter?—W. MASH.

[Late and weak swarms may be advantageously united or returned to their parent stocks in the manner you describe. Nadirs must be removed in the autumn, and any worker combs which they contain should be taken care of, as they will be found very valuable either as guide combs or as decoy combs for supers.]

As your object is to obtain eggs only, keep Golden-pencilled Hamburgs.]

HAD your correspondent "H." (see page 161), proceeded as follows, the morning light, instead of revealing the "melancholy sight" which met his view, would in all probability have shown but two empty boxes without a single dead bee on either floor board:—

He ought to have driven the cottager's bees into a spare empty Stewarton hive in the one case, and into a Woodbury in the other, *leisurely*, so as to ensure the due filling of the honey bags, setting down each close by the hive to which it was to be united till dusk, then raised the Stewarton stock, and as quickly as possible set it down upon the corresponding hive with the driven bees, closing the upper entrance, and gently withdrawing the slides of the lower box nearly to their ends, and in like manner disposed of the driven bees in the Woodbury, after of course removing the crown board of the lower box. A few puffs

of smoke to both hives just before uniting "makes assurance doubly sure."

I cannot say I ever approved of Payne's plan of uniting. Knocking out bees on a cloth spread on the cold ground "an hour and a half after sunset" is anything but sound practice, as a considerable number will inevitably find their way under the cloth, crawl away to a distance, and become chilled and lost; and to set a cold draught passing underneath is the very thing to arouse them, and should the guards seize one or two of the incomers, skirmishes would quickly follow, and the probability is a general battle would be the result. If the bee-keeper has not a sparo hive with bars and slides, far better for him to drive up the bees in the stock with a good puffing smoke, then invert the stock, and sprinkle the combs and inmates with a small quantity of thin sugar syrup, flavoured with a little peppermint. Serve the driven bees in like manner, and instead of knocking them out on the ground, knock them at once into the inverted stock; set on the floor board, stop up the door, re-invert the stock in its place; after a minute or two open the entrance, the object of closing it being to prevent the bees rushing out in the first confusion, and provided the honey bags of the driven bees be well laden, fighting I have never found ensue in such circumstances.

Well filled driven bees invariably ascend with pleasure and delight from their empty hives into a fully combed stock set over them, on the removal of the slides, and are as invariably made welcome. I generally dispense with the smoke, the syrup, and the peppermint unless the evening be somewhat chilly. The beginner may employ all these, as they induce confidence, and during a warm evening, if at all neatly managed, by either the above modes success is reduced to certainty.—A RENEWESHIRE BEE-KEEPER.

BEES NOT THRIVING.

I HAVE kept bees in one of Marriott's humane bee hives since May last. They have worked so as to about half fill the hive with comb, but much of this appears to be empty. In August I put on the super—a rather large bell-glass. In this they did not work at all, and I have now removed it, closing up the apertures. I have also now narrowed the opening to about half an inch. A few bees go in and out in fine weather, but through the windows the hive appears to be almost deserted. About three months ago the hive was blown over, but was replaced without damage, and the bees have continued to work in it since. Its situation faces the south, and is sheltered from the north by a holly hedge. When the hive was replaced after the accident referred to, its position, with reference to the opening, was altered by my gardener. The part that was at the back was brought about one-third of the circle towards the front. This may have puzzled the workers.—J. S., *Lee*.

[Your swarm has not done well, owing either to a failure in the honey harvest, or insufficient numbers at the outset. It would be much benefited by the addition of a stock of condemned bees in the manner described in page 60 of the last edition of "Bee-keeping for the Many." In any event it is likely to be short of food, and this is a question which should be at once decided by weighing. The nett contents of the hive should reach at least 15 lbs., and anything short of that weight should be immediately made up by feeding with an inverted bottle. If the entrance is made in the floorboard, it probably remains in its original position, and in this case no harm whatever was done by the hive being partially turned round when replaced after its capsize; but if the entrance was shifted, the bees, doubtless, suffered some temporary inconvenience.]

FOUL BROOD.

Prior to the 20th of last month, we had a week of chilling east and north-east winds, and many hives that showed great activity about the beginning of the month passed suddenly into a semi-dormant state. With a view to solving the origin of foul brood, I shall be glad to learn whether any apiarian now finds foul cells in those hives which at the beginning of the cold weather had brood in the larva state, and only a scanty population.

The "RENEWESHIRE BEE-KEEPER" evidently inclines to the idea of over-heating as the cause. When he first stated his views, I was much impressed with them, but circumstances have since occurred which lead me to receive them less favourably. Some time ago when the weather was so warm that it

seemed impossible, our friend "APICOLA," had a batch of nearly matured brood placed over a strong hive chilled to death.—R. S.

LARGE HARVEST FROM ONE HIVE.

WHEN I transmitted some remarks on brood in supers, I gave as an illustration a strong octagon hybrid Italian colony of my own, estimating the this-season's harvest from it at 160 lbs., or the average full contents of the eight supers then taken, not having the weights beside me, and some of the supers still to weigh. As it may prove interesting to your apiarian readers, I now append the exact weight of each, and the date it was harvested, together with an estimate of the honey left in the stock hive.

July 9.—1	Octagon Super.....	23½ lbs.
" 9.—1	" " ".....	23
" 16.—1	" " ".....	21½

Bees' comb and pollen, allow....		9
Surplus honey in spring, suppose		10 —40½
Net body honey....		30 — 30
Total harvest....		194½

As the honey harvest terminated in this quarter by the middle of August, I have no doubt, had this colony been weighed then, the result would have been a weight of upwards of 200 lbs.

This large yield is mainly due to the continuons dry warm weather of the late summer, so very unusual to us pluvians of the west coast, enabling strong colonies of our little favourites to show what they could do when fairly at it, more than to any great flow of honey or prevalence of honeydew, which latter was very unusual. The white clover from which the above was chiefly gathered, was certainly rather above, while the yield from the lime trees fell considerably below, the average, owing to the blighting wind, which despoiled them of their foliage early in the season.

Had the colony been moved to the heather, from the large band of reapers, the harvest would in a very few days have been largely augmented, and I need scarcely add, that the whole was the *bona fide* ingathering of the bees, no feeding in any form, to the extent of even a teaspoonful, having been administered to this stock for the last two years. The very reprehensible mode resorted to by some bee-keepers of feeding largely with sugar syrup, with the view of getting up and more thoroughly completing supers, and palming the produce off on dealers as honey, is most disgraceful to themselves and injurious to the more general consumption of the commodity.

I may give at a future time a report of the harvest sipped by my other colonies, which was good, but nothing approaching the above—by far the best colony ever possessed by—A RENEWESHIRE BEE-KEEPER.

THE BERKSHIRE HIVE.

I HAVE often seen the question asked in your Journal as to what is the best hive. Now, though there can be no doubt but that the Woodbury frame hive is the best for scientific purposes in the hand of the skilled apiarian, yet for all other purposes I have seen nothing equal to the Berkshire hive, as constructed by Mr. James Sadler, of Sonning, near Reading, and for which he obtained a silver medal at the Reading Industrial Exhibition. For facilities of observation, for simplicity of management, and for profit, all combined, it is unrivalled.

The stock box is made of inch wood, 11½ inches square by 10½ inches deep, inside measurement. There are three large windows, 10 inches by 8, by which the apiarian is admitted to a full view of the interior of the hive—that is, one on each side except the front. The advantages of glass are thus combined with the utility of wood. The honey is taken from the top of

the hive by means of two boxes. They have glass at each end, and one of the ends can be detached for the easy removal of the combs. The bees are admitted into the supers by means of long holes nearly a quarter of an inch wide, so as to admit only the worker bees. The holes are at the ends of the top of the stock box, so as not to interfere with the centre of the hive where the breeding chiefly goes on, and are protected by wooden slides.

The system of management is as follows:—One super is always kept on, and the slide that communicates with it open, to allow the condensed vapour to pass off. As soon as the bees have filled the stock box they take to this super, and when it is three parts full the bees are then admitted into the second super. By this method one super is always filled before the other, and is then taken off and replaced by an empty one; and thus the bees have always plenty of room and air, and have no need to swarm, and a continual supply of honey is obtained as long as the season lasts.

This year Mr. Sadler has taken 40 lbs. of honey in supers from one hive, and in 1866 he took nearly 60 lbs. from each hive without interfering with the stock box; and this, it must be remembered, in an indifferent honey neighbourhood, where there is no heather, and the bees are entirely dependant for their stores upon the flowers, and their harvest ends with the cutting of the grass in the meadows.

Mr. Sadler's hives have never thrown off any swarms, and he never primes his supers with empty comb, as he finds it quite unnecessary. When he requires swarms he purchases them from his neighbours, as he finds it more profitable to keep his own hives entirely for the produce of honey. The bees are confined when necessary by a piece of fluted wood which exactly fits the entrance. For simplicity of management there is certainly no hive equal to this, and at so low a price—viz., £1, which includes the complete hive with two supers.

Mr. Sadler's bee sheds, too, are worthy of notice. They are so thoroughly rustic, and so very pretty for either the garden or the lawn.—S. B.

THE HONEY HARVEST IN LANARKSHIRE.

I am indebted to Mr. A. Pettigrew for the following extracts from a private letter bearing date the 25th of September, and giving particulars of the recent honey harvest in his native village, Carluke, in Lanarkshire.—A DEVONSHIRE BEE-KEEPER.

"We only brought our bees home from the moors the week before last. The weather was fine, and we thought they would be gaining weight, but we were wrong. Henshilwood had his home about ten days before us. We thought he would lose by it, but not so. Ours lost 8 or 10 lbs. from the time he had his home till we had ours. The heaviest top (first) swarm I had was 104 lbs. when it came home. My weights (steelyard) only weigh 112 lbs. I weighed the same top about a fortnight before it came home, the steelyard was drawn out to 112 lbs., and did not lift it, so it was a few pounds more. I had another top swarm about 6 lbs. lighter. Our best second swarm was 75 lbs.; our old stales (stocks), 50 and 60 lbs. I went over to R. Scular's to-day. His heaviest tops were three, about 120 lbs. each, and one 130 lbs.; he had also two second swarms, one 80 lbs. and the other 90 lbs. J. Jack, weaver, had two stales in the spring. I daresay they did better than any person's here. He had a top 161 lbs., another 104 lbs., and a second swarm 68 lbs. I did not hear the weight of the old ones, but he took 46 pints of honey from the produce of the two stales. Samuel Denster had two stales in the spring. His two tops were 110 lbs. and 148 lbs. So you see I am far behind this year, but I see the reason why—Henshilwood, Jack, and Denster took theirs away to the clover, the two first to Newbigging, and the latter to Hankerton. They did a very great deal better at these places than they did at Carluke. I forgot to say that my brother had a top of 130 lbs., the rest of his were very middling. You have already the news about Henshilwood. His heaviest top was 168 lbs., but it was put into a good skepful of combs, which gave it a great start. He had not another above 100 lbs.—R. R."

OUR LETTER BOX.

GAME COCK'S LEG BROKEN.—POULTRY FOOD (*A Beginner*).—In the first place, we do not think the cock will ever be of any service. We dislike tail wheat as food for anything but very small chickens, and even with them it is what it is to everything else—a plaything. There is no food, or rather feeding on it. You need not be surprised if the hens do not lay till November; but you must feed better and give more variety—a little whole barley, a handful of Indian corn, table scraps, and a lettuce. You

do not state what run your fowls have beyond their house of 5 feet square. Have they grass? If they have not, they want some. What extent have they, and of what nature?

LOSS OF A CLAW (*A. S. K.*).—The accidental loss of a claw would not disqualify a bird, or unfit it for competition. It would be a disadvantage in deciding between two pens of almost equal merit.

OLDHAM POULTRY SHOW (*Subscriber*).—We have had a somewhat similar circular from another show committee, and the only "very painful" circumstance in either case is, that any committee of gentlemen should ask others to bear any portion of the loss which that committee have incurred. Consult your solicitor as you propose.

DURBURG AND TRIMMING GAME STAGS.—In the ninth line from the end of the article on this subject, in page 272, the word "of" should be inserted before "Black-breasted Red."

DARK GREY DORKINGS' EAR-LOBES (*Scot*).—It is preferable that a Dark Grey Dorking should have a red ear-lobe, but if it is entirely or partially white, it is by no means a disqualification. The ear-lobe in a Dorking fowl is immaterial.

WHITEHAVEN POULTRY SHOW.—We are informed that the dates of this Show have been altered to the 12th, 13th, and 14th of January, 1869.

DUCKS AT FARNWORTH SHOW.—Both first and third prizes in the Any other variety class were awarded to Mr. T. C. Harrison, of Hull. The error is that of the list sent to us.

POULTRY DISEASED (*C. L.*).—We do not think you will lose many of your fowls. We believe the disease you mention has been brought by the French fowls. Whether it be that they are not yet acclimatised, or that it is their natural state we cannot say, but all of these new breeds are subject to illness of a serious and often fatal character when they are chickens, and to relapses in adult life. In the latter case they recover rapidly. We have noticed that these maladies are prevalent immediately after heavy rains. We have seen at such times these birds leave the fine spring water with which they are supplied, in order to drink from any dirty little puddle, and they are sure to be ill after it. We advise you to keep them almost without water, and especially to see that there are no puddles of water about. Let them have drink twice or thrice a day, but not always by them. Continue the camphor. Feed very sparingly, and give only bread and ale. If you can do it, separate the Cochins and Brahmas from the French breeds. A little change of condition may be looked for as the air becomes damper, its temperature lower, and the nights longer. Many fowls are out of condition from moulting, but there should be nothing like such disease as you mention. As appetite returns, you will, of course, increase the quantity of food.

COMMENCING POULTRY-KEEPING (*Two-years Subscriber*).—If you wish to have the best possible return with the least trouble, we advise you to keep Brahma Pootras. They are very hardy, good layers, good sitters, and good mothers. They are also very useful fowls. They will do well in such a space as you name. Is there any grass in the run in front of the house? The floor of the house must be earth; clay beaten hard and covered with gravel is an excellent flooring. Neither in the house nor in the run should there be any boards, stones, or bricks. If it be necessary a little of such may be left outside, but inside there must be nothing but earth. The house should be ventilated just under the roof by openings or windows that can be shut in very severe weather.

RUNT PIGEONS (*R. Barney*).—We have a letter for you, and will forward it if you send us your direction.

CANARIES ATTACKED BY PARASITES (*H. J. G.*).—"I know of no means of eradicating them but extreme cleanliness, and even then it is a most difficult matter. I will take an early opportunity of writing a short article on the subject. Meanwhile try the Persian powder for destroying vermin—I think that is the name; but it is advertised daily. It is sold, with an apparatus for using it, at a very cheap rate, and I have known it used very effectively. Blow it under the feathers.—W. A. BLAKSTON."

CANARY WITH BLACK LEGS AND BEAK—GROATS AS FOOD (*A. T. E.*).—Say what variety of Canary the bird is. Some kinds are black in the points mentioned, the blacker the better. We have not known a clear bird affected, and certainly should not attach blame to the saffron. Groats are used as food by many breeders, and form a considerable ingredient in the contents of the bags of seed sent with birds for exhibition.

FEEDING BEES (*J. C. J.*).—Your bottle-feeding must have failed either through the mouth being too wide or from some error in management, but as you do not give particulars we sorely know how to suggest a remedy. Read our reply to "TYRO," in page 26, and if robbing take place insert the bottle-mouth in a close-fitting perforated block of wood, a precaution which will stop pilferers at defiance.

SWEET CIDER (*H. L.*).—We believe that it is no more than cider bottled before the fermentation is completed. We shall be obliged by practical information on the subject.

RABBIT DISEASES (*E.L.*).—To cure the scurf which appears on the nose, feet, and ears, give each a teaspoonful of flowers of sulphur mixed with their bran daily, and a good supply of carrot and lettuce. The young rabbits dying without any apparent cause, is, probably, occasioned by their moulting, or changing their fur. At that time they should be kept warmer and fed more liberally—that is, on more nourishing food, such as boiled barley; and if, notwithstanding, some die, give the others daily fifteen grains of camphor each until the mortality ceases.

RABBITS (*J. E.*).—If you enclose seven stamps with your address, and order "The Rabbit Book," it will be sent from our office free by post. The ears are measured from the tip of one ear to the tip of the other.

POULTRY MARKET.—OCTOBER 14.

THERE is a large supply of goods in the market, but the bad demand and the hot weather cause things to be unusually dull.

From observations taken near London during the last forty-one years, the average day temperature of the week is 53.6°; and its night temperature 39.8°. The greatest heat was 69°, on the 22nd, 1863; and the lowest cold 17°, on the 23rd, 1859. The greatest fall of rain was 1.08 inch.

MERITS AND DEMERITS OF SOME BEDDING PELARGONIUMS.

FOR some time I have been intending to record in your Journal the result of two years' trial of ordinary bedding Pelargoniums, but have hitherto been prevented by not having been able to find sufficient time to devote to the subject, and I am afraid the notes I now send you must necessarily be imperfect.

I shall, of course, be obliged to tread over ground that has already been gone over by many of your correspondents on the subject; for as the Pelargonium is certainly the most useful and easily cultivated of all plants for bedding purposes, it is, if I may use the expression, everybody's plant, and every lover of a flower or of a garden is interested in recording his own experience with regard to it.

Our last two seasons, one exceptionally wet and cold, the other even still more remarkable for its extreme heat and drought, have been crucial tests for the constitutional vigour and general utility of the different kinds of Pelargoniums, and those that have been good in both of the last two seasons may, I think, be safely relied on, and recommended for ordinary bedding purposes. I will not enter into detail about 1867, but will only refer to it from time to time in my notes on the Pelargonium in 1868.

I will begin by stating that, in order to give Pelargoniums as nearly as possible the same conditions of trial, I planted some diamond-shaped beds in a long border, which surrounds my garden, with thirty different kinds of plain-leaved and zonal Pelargoniums, not variegated, each bed being edged with variegated *Arabis albidula*. Each bed held sixteen plants, which were all, with but few exceptions, struck and potted off at the same time of the year. The list of those I tried in this way is as follows:—

NOSEGAYS.—*Stella*, Lord Palmerston, *Cybister*, Black Dwarf, Minimum, Waltham Seedling, Rival Nosegay, Duchess, Indian Yellow, Orange Nosegay, Amy Hogg, Violet Hill.

ORDINARY ZONALS.—Victor Emmanuel, Brookfield Pink, Trentham Rose, Merrimac (Lemoine), Rose Rendatler, Dr. Lindley, Glorious, Vivid, Eclipse, Madame Vaucher, White Tom Thumb, Madame Werle, François Desbois, Madame Rudersdorff, Gloire de France, Christine, Comte de Morny.

Besides these in the thirty beds, I also tried in some larger mixed beds in the garden Rebecca, Princess Lichtenstein, Louisa, Excellent, Alexandra, Roi d'Italie, Pink *Stella*, Mrs. W. Paul, Rose Perfection, Ratazzi, &c.

I have not classed the varieties in any order, but will endeavour to do so now.

NOSEGAY PELARGONIUMS.

1. *Waltham Seedling*.—Dark rich crimson. This has been decidedly the best of the dark-coloured Pelargoniums with me this year, and it also stood the wet of last year well, though not blooming so freely, as, in fact, no Pelargonium did last year. One of its great merits is its short, stiff, flower stalk, which throws the bloom just the right height

above the plant, and it is not dashed down with wind and rain like some.

2. *Black Dwarf*.—Next in point of colour, but the flower stalks are not stiff enough, and the flowers are constantly dragging on the ground.

3. *Stella*.—Still very good. The flower stalk too long, and habit too straggling.

4. *Rival Nosegay*.—Very good, but not quite free-flowering enough. For those who prefer a pure green leaf this is a desirable variety.

5. *Lord Palmerston*.—Lighter crimson. There is no Pelargonium of this colour better, and it is on the whole the most constant and free blooming of any, producing a greater succession of flower buds than any other kind I know. Its fault, again, is that the flower stem is not strong enough for the mass of bloom it has open at once; and here I think Duchess of Sutherland, a slightly lighter shade of colour, may surpass it.

6. *Minimum*.—Dwarf, of the same colour as the last; smaller heads of bloom, but very free; would do to edge a large bed of Lord Palmerston.

7. *Cybister*.—The best scarlet either in the Nosegay or Zonal section. Rather too straggling a habit, and in this respect Lady Constance Grosvenor will, very probably, be superior, but it cannot surpass it for freeness or constancy of bloom.

8. *Duchess*.—Rich cerise; fine truss. Rather too strong a grower, and not so free in wet weather.

9. *Violet Hill*.—Cerise. A beautiful, free-blooming, dwarf plant, and, in my opinion, the best of its colour, especially in good rich soil. In poor land it would be too dwarf.

10. *Amy Hogg*.—Cerise, shaded with magenta. Very free blooming, and an interesting variety of colour, but the flower stalk is too long to stand wet weather.

11. *Indian Yellow*.—Light cerise. One of the very best; a constant bloomer, and stands dry weather better than any variety.

12. *Orange Nosegay*.—Rich orange. Rather too free a grower, and the heads of bloom not quite large enough, but otherwise a very desirable variety.

This brings me to the end of those Nosegays I tried in separate beds. Among the mixed sorts, of which I had not quite enough, or which I have hitherto only had in pots, are Rebecca, very good; Lady Constance Grosvenor; Duchess of Sutherland; International, sent out by Mr. C. Turner, very promising; Mrs. Laing; and King of the Nosegays, also very good. We want, if it could be obtained, a white Nosegay, and a light salmon-coloured one of the Madame Rudersdorff shade; and any person who could raise a white Nosegay as good as Waltham Seedling or Violet Hill would be a great benefactor to those who delight in bedding-out gardens.

ORDINARY ZONAL PELARGONIUMS.

On these my remarks will be much shorter, as I am convinced that the Nosegays are destined in the end to surpass all others for bedding purposes, their greater constitutional vigour and hardness enabling them to stand the changes of the weather so much better; for I find, as a general rule, that those which grow and flower well

in dry hot weather, will also succeed better than others in wet.

Scarlet.—Victor Emmanuel, Dr. Lindley, Vivid, Eclipse, and Glorious.

Of these, Victor Emmanuel, Vivid, and Eclipse are nearly of the same shade of colour, and this season did very well, except in the very hottest weather; but both Vivid and Eclipse are of too strong growth for wet seasons. Dr. Lindley is not free-flowering enough, and the habit of the plant is too upright. Glorious is a very good dwarf, nearly of the same colour as Roi d'Italie, and would do best in wet seasons, as, if the plants are bedded out too small, they burn up in dry weather.

Cerise.—Herald of Spring, Trentham Rose, Merrimac (Le-moine), and Comte de Morny.

These are all good, and I think Trentham Rose not surpassed yet in its colour. Comte de Morny has a fine branching habit, and the flower is of a distinct shade of colour, with a large truss. Herald of Spring is rather too strong and upright in growth for wet seasons, but stands dry weather better than most Zonals. Merrimac is also very good, and has a fine truss, but is rather too upright in its growth.

Pink.—Brookfield Pink, Gloire de France, Christine, and Rose Rendatler.

Of these, Rose Rendatler is by far the best pink, though of rather too light a colour, but its immense flower trusses on fine stiff stalks enable it to resist both dry weather and wet better than any other pink. Brookfield Pink is a sport from Trentham Rose, propagated and made constant by A. Walker, Esq., of Brookfield. It will not, however, stand sun. Christine is useless in dry weather. Gloire de France is not free-blooming enough.

Salmon.—Madame Rudersdorff, François Desbois, and Madame Werle.

Of these, Madame Rudersdorff is the best, and is very free-blooming, especially in dry weather. Madame Werle is of too strong and upright a habit of growth, and ought really to be called white, with a pink eye. François Desbois is good, but not so good as Madame Rudersdorff.

White.—Madame Vaucher and White Tom Thumb. I can detect no difference between them. They are the best whites as yet sent out, but are neither free-blooming nor constant enough, and in wet weather, though the white is purer and less pink, yet the plants become too coarse. A good white is, as I before said, still a desideratum.

Amongst others I did not put into self beds, and which can be recommended, are Roi d'Italie, Excellent, and Rose Perfection. The last I think very promising. Excellent will be well known by most of your readers. I do not like it myself so much as others of its colour. I forgot among the Nosegays to mention Pink Stella, which I am in hopes will be a good pink, and Lady Cullum, lilac Nosegay, which is good for variety, though many would say it has rather a washed-out look.

I will now conclude these notes, and send you, with your permission another time, some remarks on the Variegated Bicolor and Tricolor sections, and also on the winter management of bedding Pelargoniums, as I am sure much harm is done by the general recommendations which are so common in all gardening periodicals at this time of the year. "Keep all plants cold and dormant during the winter, giving no more water than is absolutely necessary." The consequence is, Pelargoniums lose all their finer fibrous roots in the winter, many damp off altogether from want of growth, and they are at least a month later in coming into bloom in the spring than they ought to be.

To sum up, the best Pelargoniums of those sufficiently long before the public to be well known, are Waltham Seedling, Lord Palmerston, Stella, Cybister, Violet Hill, Amy Hogg, Indian Yellow, Orange Nosegay, Rose Rendatler, Herald of Spring, Comte de Morny, Trentham Rose, and Madame Vaucher.

I have named one of each shade of colour sufficiently distinct to bed as a variety, the different shades of cerise differing only in tone.—C. P. PEACH.

greatly esteemed and more relished than the Morello Cherry, which it somewhat resembles. The fruit is also used for bottling, and for preserving like other Plums and Cherries. From one tree Mr. Matheson had increased the stock of this to ten or twelve, and by the Marquis of Exeter's desire many had been distributed amongst his tenants, so much are its qualities estimated in that district. As a simple ornamental flowering tree, this Plum, or *Prunus*, is generally to be met with. It is a distinct species. It is the first of all the *Prunus* family to blossom, in fact, the first-flowering tree of the season. It is frequently covered with its small but pretty white blossoms in the beginning of March as with a sheet of snow. Through this habit of early flowering, however, we generally lose the fruit by frosts, excepting in unusually open seasons, and in some favoured situations, as at Burghley, which is high and dry. The tree is of slender growth, but attains a great size—from 30 to 40 feet; the leaves are very small and rounded; fruit medium-sized, of a slightly oval shape, its colour pale red, with a long slender stalk like a Cherry. Indeed, when gathered, a dish of them more nearly resembles one of red Cherries than of Plums. The flesh is yellowish, sweet, with a slight acidity, and juicy. Ripe early in July, but will hang on the trees a long time. At Arundel Castle I recollect seeing some ripe fruit of it on a small plant in the beginning of March; this tree flowered in October. It was there called Roblet; but it has many synonyms, as Early Scarlet, Miser Plum, Virginian Cherry, &c.

As an ornamental early-flowering tree alone, independently of the fruit, the Cherry Plum is worthy of a place in every garden.—ARCHAMBAUD.

FLOWER-BEDS IN AUTUMN.

SILVER-EDGED *versus* TRICOLOR PELARGONIUMS.

BEFORE the lingering beauties of the past summer are too far injured by autumn dews and frosts, it would be well if everyone would note the merits of the different plants composing the summer display, and if such notes were coupled with others taken at various times during the year, there might be collected a large amount of information of greater value than the most careful description made from the appearance of a plant at one time only. Of course, where notes of this kind have not been commenced, it is now too late to do more than examine the condition of the plants at the present time (the middle of October); and calling to mind how they have behaved all the season, we may, from a plant's long or short continuance in beauty, give it a good or an indifferent character.

Generally speaking, plants presenting the greatest abundance of flowers at one time are not those likely to give a long continuance of bloom, and many plants having a tendency to ripen seed abundantly are also liable to go off, and blanks are the consequence; but I will not enter into these matters just now, but will simply look over the beds before they are disarranged, and see what plants maintain their beauties till the last, and on that account have a greater claim to our attention than those presenting for a shorter period a good or passable appearance.

Another circumstance must also be borne in mind—the distance from which a plant is viewed. Some experience in the latter respect has led me to form an opinion which I imagine will be pronounced heresy by the authorities in such matters at the present day; but I nevertheless assert it, and call on those having an opportunity to give an opinion, to do so. My idea is this, that a good Silver-edged Pelargonium looks better than the very best Tricolor one of the day at any distance exceeding 60 yards, nay, more than that, I may say that Golden Chain looks better than Mrs. Pollock at that distance, or beyond it. The reason is obvious, the eye cannot detect the beauties of the markings in the leaf, and the dark zone mars, rather than beautifies the foliage, while the best Silver-edged Pelargoniums present only two colours, white and green, and the green portion of the leaf is often much paler in the white-edged section than in any other, thereby helping to intensify the already prevailing white. The presence of dew, likewise, which at this advanced season hangs on plants during a great part of the day, gives a richness to the white-edged Pelargoniums rather than otherwise, while it clouds the Tricolors.

It may be asked why make the comparison now, why not go back to July? To this I am also agreeable. Inquire in what condition most of the Tricolor kinds were at that time, and in most cases the complaint would be, that the foliage was scorched and

THE CHERRY PLUM, *PRUNUS MYROBALANA*.

When at Burghley Park Gardens, Stamford, last July, I observed several good-sized trees of this pretty little Plum, quite heavily laden with fruit. Mr. Matheson, the very excellent gardener there, informed me that it was very much used by the Marquis of Exeter's family, when quite ripe, for the dessert, but principally for tarts, for which purpose it was

disfigured by the sun, while the Silver-edged varieties seemed not to suffer much; that it was not until the middle of August, and later, that Mrs. Pollock (which I name as the best known of its class) presented foliage at all true to its character. Later in the season, however, it has been all that could be desired. Those who admire its fine foliage may not regard the appearance of the plant at a distance as of much importance; but they must have had to lament so much of the summer passing away before the leaves presented their markings in any degree of perfection. The appearance of a Tricolor Pelargonium in ill health, is, on the whole, worse than that of other kinds; for these reasons, therefore, I am disposed to place this class, as a whole, second in utility for flower garden purposes to the Silver-edged Pelargoniums, and I hope that in putting forth this view, I am not too late to enable those having both classes in good condition to make the comparison which I ask them to do between plants of each class at a distance as well as close to the eye.

Having said this much on the comparative merits of Tricolor and Silver-edged Pelargoniums, I will ask space for a few remarks on the appearance of some other plants at the present time. *Gnaphalium lanatum* looks richer when wetted with rain or dew than it does in hot sunshine, especially when it has been allowed to grow, and as it were throw its arms over its neighbours a little. An equally handsome plant with white foliage, is *Arctotis repens*, which with me has been much admired. This also looks well in autumn, or, in fact, at all times. The Golden Pyrethrum has likewise returned to its proper colour, which it partly lost in July and August. The reverse is the case with *Chrysanthemum Sensation*, which seems to lose its foliage.

Among dark-foliaged plants, the rich colour of the *Colens* is beginning to bleach, and *Amaranthus* is in places showing signs of giving way, while *Iresine* is all that can be wished. Those who have a good-foliaged Beet will probably point to it as the most ornamental plant of the season, but as I have not grown it for decorative purposes I must confine myself to asking what it was like before the 1st of August.

The autumn also brings out the *Cuphea* to greater advantage, and I may mention, that for vases in shady places, I know of no plant more suitable than *Cuphea platycentra*, and its hardiness enables it to disregard slight frosts. *Nierembergia gracilis* was, perhaps, better covered with flowers prior to the heavy rains at the end of last month, than anything we had, and it would present a good appearance again if dry weather continued. The new hardy *Nierembergia rivularis* has not done well with me, and the foliage of *Wigandias* and *Solanums* has not been so good as in 1865. The Castor Oil plants, however, are quite as good, and some are perfecting seeds.—J. ROBSON.

PHYTOLACCA DECANDRA.

Your correspondent who was so surprised at seeing this plant growing out of doors at Brussels might see it flourishing like a weed in my garden at Guildford. A few years ago Mr. Weaver gave me a plant of it, which I took up and nursed in a pot for the first winter; as, however, I found that some bits of the root which I had accidentally sliced off with the spade sent up vigorous plants in the spring, and also that numbers of seedlings were appearing on all sides, I determined to coddle no more. My plants now remain in the open ground without any protection, and increase enormously in size. They are at the present time in great beauty. In the spring the spade comes into requisition for the purpose of slicing the plants into manageable size, and the Dutch hoe destroys hundreds of seedlings.—H. G. MERRIMAN, *Royal Grammar School, Guildford*.

This plant is perfectly hardy. It has stood for many years in the gardens of the Royal Horticultural Society, Chiswick, without any protection in the open border. Every autumn it is exceedingly handsome with its long spikes of dark purplish fruit, which are very striking. It seeds very freely—so freely that some seasons the young plants come up in spring as thickly as Groundsel. A still more pretty kind, however, which is also to be seen at Chiswick, is *Phytolacca villosa* (?), which is also hardy. Its large Dahlia-like roots require but a spadeful of ashes for their protection during winter. It grows very strong—to a height of about 6 feet, and branches much, forming a perfect bush of from 4 to 6 feet in diameter. Throughout the summer it is handsome as an ornamental-foliaged plant; and when covered, as it is from the end of July to the end of

the season, with its long drooping racemes of bright dark purplish fruit, it is decidedly one of the handsomest hardy plants to be seen. This plant is much more seldom met with than *P. decandra*. If I can recollect aright it is the same plant as used to be grown as a stove plant many years ago, at all events it is remarkably like it. Both of these plants ought to be grown in every garden.—B.

DESTROYING RATS IN GARDENS.

A most unsavoury subject, but, unfortunately, one which sore against his will, is often uppermost in the thoughts of the gardener. Most of his duties are labours of love; but the keeping of these pests at bay, and laying deep, dark plots for their destruction, can only be appropriately gone about with a slouched hat, a stern brow, and a great amount of deadly hatred in the not-otherwise-unkind heart.

It is said of a great General, that when he wanted a man capable of doing a daring deed, or executing a task where strength of purpose and great sagacity were indispensable, he always selected one with a long nose. Of this being an infallible criterion I have some doubts, and if I—not being a General, wanted a man possessed of these qualifications and several more equally serviceable, I should, in preference, certainly pitch upon a man capable of out-witting a host of those clever vermin—rats.

Our great enemy, the common brown rat, is supposed to have been imported into this country from India about a century and a half ago. Previous to its introduction, a smaller and less destructive race of black rats held undisputed sway, but are now almost, if not totally exterminated by their brown brethren. The latter have since been distributed all over the civilised world mostly by British shipping, so much so, that it has become a common saying among sailors, that "rats, Scotchmen, and bad weather are to be found everywhere."

In attempting to wage war successfully against rats, their habits must be closely observed, and their instinctive powers somewhat correctly estimated. It is well known that their sense of smell is very acute, and that they depend more upon it for guidance in their search for food and in avoiding traps than they do upon either their eyes or ears, and this circumstance is accordingly taken advantage of by the rat-catcher in many ways. They have also very retentive memories, so that if one makes a narrow escape to-day, he is not likely to forget it for some time to come. Owing, no doubt, to their eastern origin, they are very fond of warmth, and they do enjoy themselves immensely in running up and down among a lot of *Verbena* cuttings plunged in a hotbed, stopping now and then to nibble over a pot of the last new sort, just because they feel so happy. But over and above these traits, long years of conflict with man, through thousands of rat generations, have battered into their natures an amount of general cunning not easily over-matched.

Where rats are very numerous, and where they are at liberty to come and go when they choose, owing to the garden not being entirely enclosed by high, well-coped walls, the only efficient means of sensibly diminishing their numbers is by poison; trapping, as ordinarily practised, is little better than labour lost under these circumstances. From their extreme wariness, even poisoning them is no easy matter; but after much experience in this detestable business, I have found the following method very successful:—Select an empty quarter not far from their usual runs, on which to commence operations; on this place in heaps a few barrowloads of warm stable dung, spread it out in the form of slight hotbeds, and over each place a one-light frame, if such are to be had, if not, a few large hand-glasses. Precure some coarse suet, tallow, or any fatty matter, which, when melted down and mixed with oatmeal or bran, forms a pastry of which rats are very fond. Put a little of it into each frame, and shut it up, as if most anxious that no rat should enter. The first night after this is done will most likely be spent by the enemy in reconnoitring; the next in breaking in and discussing the savoury morsels. Fresh supplies must be put in every day, increasing the quantity each time if it is all eaten. This is what may be termed educating the "varmint," and may be continued for four or five successive nights, after which, by way of change, similar food well seasoned with arsenic may be substituted, and it will be eaten up as greedily as the rest. Some employ strychnine instead; but it renders its victims poisonous, and being thus additionally dangerous, I have never had the courage to use it. The poisoned food should only be supplied for two or three nights

at most, for by that time the survivors will have begun to suspect foul play, and will not eat, so that further education and stronger inducements will be necessary. For this purpose obtain from a chemist some oil of rhodium, aniseed, or musk; impregnate the food with one or other of these strong scents, also some cotton rags with which trails should be made from those parts of the garden most infested, towards the frames. The infatuation with which they follow these trails indicates a weak part in their crafty natures, and is often made use of to lure them into traps. Feed for two or three nights as before, then treat to another dose of poison, and by persevering in this course for ten days or a fortnight at a time, great numbers may be destroyed.

The great fault of most traps is, that in them is made no provision for hiding the fate of those caught, their inventors evidently greatly undervaluing the reasoning powers of the rat. Owing very much to this defect, no trap has yet been constructed the use of which will remain successful for any great length of time in one place, although a great amount of ingenuity has been expended in that direction. What is wanted is some engine that will admit all comers, and so effectually hide and imprison them, that they cannot communicate to outsiders the startling fact that they are in durance vile. I was recently told by a farmer how he used to capture a good many of them, and the plan is very simple. A sort of labyrinth was made—something, I suppose, in the style of the maze at Hampton Court, by setting boards upon their edges. In the middle, crusts of bread steeped in double-strong whisky were placed, and the whole covered over with a tarpaulin. Trails were then made to the door of this dram shop by dragging a roasted herring slowly over the ground. To those that entered and parroted, intoxication, bewilderment, and capture would, no doubt, be the consequences; but I am afraid they would not be numerous. Grains of *Cocculus indicus* have also been recommended for that purpose.

Some affirm that rats may be banished from a place altogether by taking as many of them alive as possible in box traps, smearing them over with coal tar, and setting them at liberty; but such treatment seems almost too cruel, even for a rat.

To some it may be of service to know that rats may be prevented from burrowing under the front walls of vineries, which are generally built on arches, by laying common rabbit wire-netting flat upon the border close to the wall, and covering it with 2 or 3 inches of soil. Although the meshes should be so large that rats might easily pass through them if clear on both sides, as in a fence, yet they cannot remove the soil from underneath.

There is no evil so bad, however, but that it might possibly be worse. In some parts of India they have a rat, the *Mus giganteus* of naturalists, and a most gigantic nuisance it must be. It is said to weigh 3½ lbs., to measure 28 inches in length, and to earn a living by burrowing through solid brick walls and carrying off full-grown poultry. What a delightful companion he would be to our friends at the end of the Journal.—
AYRSHIRE GARDENER.

MARÉCHAL NIEL AND ALFRED COLOMB ROSES.

THAT must have been a dazzling sight which your correspondent, "AN ARDENT LOVER OF THE ROSE," describes in the *Journal* for October 1st. I can well imagine the golden glory which 114 blooms of the loveliest of Roses would produce, and I can only express my regret that I was not one of the favoured few who participated in a sight which has such a fascination for rosarians. Such an exhibition tends to remove the doubts which have been freely expressed as to the good qualities of *Maréchal Niel*.

I am inclined to think that *Maréchal Niel* will prove of very vigorous growth, for during a visit which I have recently made to Yorkshire, I have seen it growing to perfection. In the garden of Mr. John Milne, of Hull, "an ardent lover of Roses" of many years' standing, may be seen a plant of *Maréchal Niel* on its own roots, which has this season thrown up a shoot now 9 feet high, and as thick at the base as one's thumb. It was still growing when I saw it on the 4th instant.

The suggestion made by your correspondent, that boxes of select varieties, such as *Maréchal Niel*, *Gloire de Dijon*, *Charles Lefebvre*, &c., should be exhibited, I cordially endorse. One of the most beautiful sights at our last Birmingham Show was

boxes of Alfred Colomb. The lovely form, full and graceful, the depth of petal and glorious colouring which this Rose uniformly presented, impressed me so favourably, that in my humble opinion Alfred Colomb must be allowed to take the foremost place in the list of Hybrid Perpetuals. It is unrivalled.—C. W. M., *Wylde Green*.

BATTERSEA PARK.

(Concluded from page 167.)

A SUBSEQUENT visit to the Park about three weeks ago, was chiefly devoted to what is known as the Peninsula garden, which lies to the left of the northern entrance to the subtropical department, and is for a considerable portion of its length skirted by the lake. Passing into this garden, the first feature that attracted attention was a cosy nook planted with tree Ferns, consisting of *Dicksonia antarctica*, *Alsophila australis* and *exceles*, and a handsome specimen of *Cyathea dealbata*. Accompanying these were *Carludovicalatifolia*, a dwarf *Pandanad* with plaited pale green leaves; *Philoedendron crassinervium*, with pointed lanceolate leaves, of which the midribs form a very thick band, flat on the upper side; *P. macrophyllum*, with broad *Caladium*-like leaves; and *Pothos acaulis*, 4½ feet in height, and very luxuriant. The Stag's-horn Fern, *Platyceurium aleicorne*, was also looking very healthy. In a corresponding shady nook on the lake side of the walk, there was a beautiful group of the Bird's-nest Fern, of which the lively green fronds indicated that the plants were profiting by the free air and liberty which they thus enjoyed. Associated with these we noticed *Philoedendron Simsii*, *Cordyline indivisa*, which stands the weather well out of doors in summer and autumn; the *Loquat*; an *Alsophila exceles*, spreading its fronds over a space 9 or 10 feet in diameter; *Latania borbonica*, and that graceful *Palm Scaevortia elegans*, which has been making fresh fronds throughout the season.

Facing the lake, but on the opposite side of the walk, an extremely effective oblong bed was planted as follows:—Along the centre were five circles, the two end ones filled with *Alternanthera amœna*; the centre circle with *Lady Cullum*, variegated *Pelargonium*, and the other two respectively with *Pelargonium Aureum*, and *Crystal Palace Gem*. These circles were surrounded with *Veronica incana*; a mass of *Alternanthera paronychioides* filling up the space between the circles and the edging of Mrs. Pollock *Pelargonium*, margined with *Sempervivum californicum*. In a trial bed of *Cannas* at the back of the oblong bed just mentioned, *Canna grandiflora floribunda* was remarkable for its dwarf habit and fine flame orange-coloured flowers, paler in colour at the base of the petals. Another variety called *Imperator*, in the same bed, was of extremely vigorous growth, having foliage not unlike that of a *Banana*.

The next beds were circles planted with *Caladium cucullatum*, and the handsome *Rice-paper plant*, *Aralia papyrifera*; the ground under the latter was carpeted with the well-known *Cyanotis vittata*, or *Tradescantia zebrina*, the whole being edged with *Vinca elegantissima*, surrounded with *Alternantheras*. Passing onwards we reached a panel bed similar in design to that already described, only the circles at each end, and that in the centre, were filled with *Gold* and *Bronze Pelargoniums*, *Arab*, *Zebra*, and *Egyptian Queen*, the other two circles being planted with *Snowdrop* and *Queen of Queens*, white-edged varieties. As before the circles were edged with *Veronica incana*, the panel was filled up with *Alternanthera amœna*, and the whole edged with the pretty *Sempervivum californicum*. This bed, like the other, had been very effective, but the *Pelargoniums* had lost much of their beauty.

A lunette bed next claimed attention. This was planted with *Polymnia grandis* forming a mass in the centre, with little blocks of the variegated *Japanese Maize* and *Amaranthus melancholicus ruber* in front, *Echeveria secunda glauca* making a beautiful edging. A similar lunette was filled with *Solanum laciniatum elegans*, with beautifully cut leaves, and large flowers, backed with *Eucalyptus globulus*, and having *Wigandia urens* in front, the edging to the whole being *Veronica incana*.

We now come to a new feature—namely, a series of mounds on the shores of the lake, chiefly covered with alpine plants, plants for the most part of small and even minute growth, offering a marked contrast to the bold luxuriance of the tropical vegetation around. One of these mounds was carpeted with *Antennaria tomentosa*, and the silvery groundwork which it forms was studded with *Sempervivum phioloides* and atro-

purpureum. On the next mound Golden Feather Pyrethrum was interspersed amongst *Echeveria metallica* and *Sempervivum Donkelaari*, and at the back there was a plant of *Sansevieria zeylanica* in quite as good condition as it is seen in the best collections of ornamental-foliaged plants, though not so large. A third mound was covered with the charming little buttoned of *Sedum glaucum*, dotted with a very effective *Sempervivum* said to be new, *Echeveria metallica* beautifully coloured, and *Sempervivum phioloides*. On other mounds the above plants were repeated in various combinations with each other, and with several more plants of a similar character. Of these *Sedum virens*, *Gnaphalium dioicum nanum*, and *Sedum ochroleucum*, formed very pretty dense tufts, those of the last named, in particular, being almost like small berries. *Sedum brevifolium* is also pretty at the end of the season.

A bed of *Pelargoniums* occurred on the grass not far from the alpine. This was prettily divided into several compartments by a zigzag band of Silver Thyme, and in these were growing several *Pelargoniums* for trial. John Heavyside, scarlet, looked very well, and King of Nosegays had fine trusses of broad-petalled flowers. After passing a splendid bed of Castor Oil plants, and a very fine one of the variegated *Acer negundo*, edged with Golden Feather Pyrethrum, we reached a magnificent plant of *Musa ensete*, with leaves 12 feet long, in a sheltered nook at the junction of two walks. This was planted on a slight elevation above the surrounding turf, and the ground beneath carpeted with the frosty-leaved *Antennaria tomentosa*.

Near this point a large piece of rockwork is in course of formation, the ground has been thrown up so as to form a bold promontory at the head of the lake, facing the south and south-east, and judging from the work already executed, an excellent imitation of natural sandstone rocks will be produced. They appear as if there had been a "fault" near the lake, and the dip of the strata is seen to be inland. This rockwork is to have basins and ledges for the growth of alpine and other suitable plants, and there are to be some small waterfalls; but very judiciously no attempt has been made to imitate mountain scenery by representing a mountain by a molehill, and a lofty rock by a large stone. Rockwork is one of the most difficult forms to imitate, so as to produce a good effect in a garden, for on a large scale it is both expensive, and occupies a large amount of space, and if small it becomes ridiculous, unless of an unambitious character. At Battersea, however, so far as we can perceive, neither too much nor too little has been attempted, and when the work shall have been finished, and the various parts clad in their living garments, we have little doubt the effect will be very pleasing. Still many shrubs and trees will have to be planted, and some years must elapse before that effect can be fully realised, for it will be a work of time to shut out Clapham Junction, with its engines speeding in all directions, and the tall chimneys beyond—the outposts of an army ever on the advance. But even at this point, whilst looking at the many spires lighted up by the autumn sunset, one is reminded by the voices of thousands of starlings seeking their roosting places on the island in the lake, that though so near a great city, our wild birds have sought and found a home where the rich and varied vegetation of the far south is flourishing in a strange land.

Returning from the rockwork there still remains a long series of beds, but as it would be tedious to particularise the planting of each, we shall only notice some of the most effective of the plants employed. Of these *Solanum robustum* was one of the most ornamental. It is a tall-growing species, with large, very spiny leaves covered, like the whole plant, with cinnamon-coloured down, and has a noble appearance. *Solanum amazonicum* is of much dwarfer habit than the preceding, and its leaves are small, and have also a cinnamon tinge, but the flowers are large and ornamental, being blue with yellow stamens. Another *Solanum*, very dwarf in growth, and set with a multitude of spines, was interesting by its prettily marbled green and white fruit. *Cannas*, including the dark-leaved *C. rubricaulis*, *Wigandias*, Castor Oil plants, *Indiarubbers*, and *Nicotiana wigandioides*, were everywhere most luxuriant. Several kinds of *Senecio* were also noticeable, more particularly *Senecio Ghiesbreghtii*, with large and beautiful green leaves, and which in January produces enormous corymbs of golden flowers; and among *Abutilons* there were several pretty kinds, especially *A. sulphureum*, with yellow flowers. *Bocconia frutescens*, which was employed at one place as an edging, also deserves mention on account of its large and elegantly lobed foliage. From one point of the walk leading from the rockwork

to the entrance, a view is obtained across a smaller lake than that in which the starlings' island is situated, and the masses of dark and green-leaved *Cannas* backed up by various trees and shrubs, with a small bed of *Salvia argentea* on the margin, had a very pretty effect.

Before quitting the subtropical department, it must be mentioned that a terrace walk has been formed on a portion of the south and west sides, giving an elevation of 20 feet and from this a view can be obtained over those gigantic *Bananas* referred to in a previous number, and a large number of the beds. The whole of this has been raised since Midsummer, 1867, principally by means of the soil obtained from the excavations for the new metropolitan railways, and which, consequently, was of a very mixed character. Notwithstanding the heat of the summer, the *Hollies* and other shrubs, though only removed in June, exhibited no sign of having been transplanted, not even a withered leaf. Of course, little basins were formed round each to hold water, with which they were plentifully supplied.

Besides the subtropical garden, Battersea Park has presented during the season another great attraction in the bedding plants which have adorned the sides of the drives and walks, especially on the river side of the Park. A ribbon border in the American ground which had been very effective earlier in the season, was planted thus—edging blue *Lobelia*; 2, Flower of the Day *Pelargonium*; 3, a double row of *Christine*; 4, *Cy-bister*; 5, Waltham Seedling, backed with Double White *Pyrethrum*. In other arrangements, the dwarf French *Marigolds* had been very useful all through the dry weather, but the rains which succeeded rendered their growth rampant. The semicircle at the principal entrance on the north side afforded a brilliant display of colour up till very lately. Both of the quadrants were planted alike; it will, therefore, be sufficient to take one. In shape the beds were what may be called (to save the use of a less generally intelligible term) oblong, with the sides following the curve of the semicircle, and with the ends swept out to correspond with the curve of the small circular beds with which these oblongs alternate. The first bed was planted with *Lucius Pelargonium*, scarlet, and like all the rest was edged with Golden Fleece, and bordered next the grass with *Cerastium tomentosum*, cut closely to a regular width of 4 inches; bed 2, a circle, was planted with *Christine*; 3, oblong, with *Lady Constance Grosvenor*, scarlet; 4, with Waltham Seedling; 5, with Excellent; 6, with *Christine*; and 7 with blue *Lobelia* and Mrs. Pollock *Pelargonium* in alternate bands across the bed, the blue flowers of the *Lobelia* setting off to great advantage the triecolor leaves of Mrs. Pollock. At the back of these beds there was one long continuous bed, as it were embracing them. This was divided into triangles by zigzag bands of *Alternanthera versicolor* with similar bands of *Cerastium* on each side of it, the triangles being alternately filled with Harry Hieover, dwarf scarlet *Pelargonium*, and blue *Lobelia*. The whole was edged with Golden Feather *Pyrethrum*, and backed with two rows of Golden Fleece *Pelargonium*, then Waltham Seedling, and another scarlet variety of stronger growth.

The last arrangement which we shall notice, was one near the West Lodge, which continued in fine condition till very lately. Though simple it is not very easy to give an intelligible description of it without an engraving. It consisted of a circle bordered with *Echeveria secunda glauca*, within which there was a ring of *Alternanthera amœna*. The large circle was centred with a small circle of *Gaiety Bronze Pelargonium*. Another circle was then described with a longer radius, filled in with *Coleus marmoratus*. The broad ring between the circumference of this second circle was then divided by segmental bands of *Alternanthera*, and the panels thus formed planted with blue *Lobelias* and *Pelargoniums* of the Gold and Bronze section. Radiating from the circle are seven somewhat club-shaped beds, the whole of which were bordered with the pretty variegated *Euonymus radicans*, very dwarf, compact, and forming an excellent permanent edging. The second rows in the different beds consisted of *Lobelia*, or *Alternantheras*; the third rows of Golden or Silver-variegated *Pelargoniums*; and the centres of rose-coloured and scarlet kinds, the beds on each side of the central one pairing with each other.

BELLE DE FONTENAY RASPBERRY.

THE Raspberry, useful as it is for jam and many other purposes, does not rank equal in importance with many other garden fruits, consequently but little attention is given to in-

creasing the number of its varieties; yet the superiority of Belle de Fontenay to most of the older kinds tends to show that the Raspberry is capable of improvement both in size and quality. Why should we not have our Cockscorn and Duc de Malakoff amongst Raspberries as well as in the family of its great rival the Strawberry?

Whether the present standard of excellence amongst Raspberries will ever be much improved upon is not of such importance as that all who care for this fruit should have the best kinds at present in cultivation; and amongst these I am strongly inclined to assign the first place to Belle de Fontenay, a sort possessing such great merit as to render it quite worthy of the certificate which was awarded it when exhibited at South Kensington, and which was my only guide in ordering it about three years ago. I am sure all who have grown it will agree with me as to its excellence both as a summer and an autumn fruit, for it is a double-fruited kind, producing its large dark-coloured fruit in large clusters on the tips of the current year's wood, which, when the autumn crop is gathered, is shortened to the usual length preparatory to yielding an abundant crop of fruit from side shoots in the following summer; after this the exhausted canes are cut away, just as is usual with those kinds which yield their fruit only in the summer.

As regards the habit of growth of Belle de Fontenay, nothing can be more healthy than its sturdy robust canes of about 5 feet in height. It is worthy of notice that, although this kind, in common with other late-fruited varieties, has produced but little fruit during the present autumn, yet what fruit has been obtained was very superior in flavour to that of ordinary seasons; for, generally speaking, the second crop of Raspberries, owing to its acidity, is only useful for tarts and creams.—**EDWARD LUCKHURST, Egerton House Gardens, Kent.**

ROYAL HORTICULTURAL SOCIETY.

OCTOBER 20TH.

FRUIT COMMITTEE.—G. F. Wilson, Esq., F.R.S., in the chair. Prizes of £2 and £1 were offered at this meeting by the Rev. George Kemp, of Sevenoaks, for the best and second best six bunches of Grapes, grown in the open air against a wall without any protection whatever. The following are the names of the six exhibitors, who sent in all seven collections:—Mr. Lynn, of Hedsor, who had Black Hamburgh; Mr. Booth, F.R.H.S., New Road, Hammersmith, sent Black Prince; Mr. Earley, of Digswell, sent well-ripened russet specimens of Royal Muscadine; Mr. Dowdney, of Dorking, large handsome bunches of Black Prince, and well-developed bunches of White Frontignan, which, however, were not sufficiently ripe; Mr. Charles Lee, of Hammersmith, and Mr. Jackson, of Titsey Park, Goldstone, Black Hamburghs; and Mr. Foster, of Leigh, Essex, who exhibited a basket of remarkably fine and well-ripened Muscadine Grapes, which obtained the first prize. The second was awarded to Mr. Lynn, for his Black Hamburghs, which were remarkably well grown, but were inferior in flavour to the Royal Muscadine.

Mr. Darlin, of St. Peter's Vineyard, Bury St. Edmunds, sent a collection of nine distinct varieties of Grapes, grown in his vineyard in the open air, which in some instances were very highly ripened. Among these were Black Hamburgh, White Muscadine, Black Muscadine, and Miller's Burgundy. There was an immense bunch of a white variety called Miller's Royal Muscadine, but which was in reality White Nice. A special certificate was awarded for the collection.

Mr. Parsons, gardener to R. Attenborough, Esq., Acton Green, was the only competitor in the class for Muscat Hamburghs, and received the first prize.

G. F. Wilson, Esq., of Gishurst Cottage, Weybridge, exhibited examples of Black Hamburgh and Chasselas Musque from a cold orchard house, the former well-ripened and well-flavoured, and the latter distinctly Muscat.

In the class for the best three dishes of dessert Apples, there were ten competitors, all of whom sent unexceptionable exhibitions, which on close examination resulted in the first prize being awarded to Mr. Whiting, of The Deepdene, for Sudbury Beauty, Cox's Orange Pippin, and Ribston Pippin. Mr. S. Ford, Leonardlee, Horsham, was second, with Blenheim Pippin, Cornish Gilliflower, and Ribston Pippin.

Mr. Robert Fenn, of the Rectory, Woodstock, exhibited thirty-six varieties of Potatoes, of which three of Mr. Fenn's selection were cooked for the judgment of the Committee. Of these, Almond's Yorkshire Hero was found to be of unusual excellence, and to it a first-class certificate was awarded, and Mr. Fenn received a special certificate for the collection.

In the class for the best three dishes of dessert Pears there were seven competitors. The first prize was awarded to Mr. Marcham, gardener to E. Oates, Esq., Hanwell, and the second to Mr. S. Ford.

H. Webb, Esq., of Redstone Manor, exhibited a dish of Brown Turkey Figs of the second crop, which were excellent in flavour.

Mr. Hill, of Kedge Hall, sent bunches of Black Morocco, Champion

Hamburgh, and Black Barbarossa. Mr. Lovegrove, of Maidenhead, sent a bottle of English champagne wine made from Black Hamburgh Grapes grown out of doors. It possessed more of the character of a French than an English wine, and was so highly appreciated by the Committee as to receive a special certificate. Mr. Cox, of Redleaf, exhibited a dish of Beurré Clairgeon, which for size and beauty have been rarely surpassed, and to which a special certificate was awarded. Mr. Marcham, gardener to E. Oates, Esq., of Hanwell, sent a dish of Cox's Golden Drop Plums, which received the commendation of the Committee for the admirable way in which they had been kept.

John Cox, Esq., of Clinton House, Weybridge, sent samples of a thin-shelled Walnut, possessed of excellent flavour. Mr. Lunnion, of Bourne End, Maidenhead, sent two varieties of Walnuts of a very large size.

Mr. Bains, of Thingwall Hall, sent a collection of Pears and two dishes of enormous More de Menage Apples, which received a special certificate. In the class for the best collection of Pearmain Apples, Mr. Cox, of Redleaf, received the first prize; and Mr. Chaff, gardener to Alfred Smee, Esq., F.R.S., received a special certificate for a fine collection. Messrs. Veitch & Son received a special certificate for a very complete collection of well-grown Endive. Messrs. Stuart and Mein, of Kelso, sent a seedling Beet, said to be a cross between Dewar's and Pine Apple, but the Committee were of opinion that it was inferior in quality to either.

FLORAL COMMITTEE.—The awards made on this occasion were but few. The specimens sent were by no means inferior, but owing to the advanced season of the year they were not so numerous as usual. Mr. Earley, of Digswell, brought out specimens of an Ipomoea, raised from seed sent from India; the flowers about an inch in diameter, of a pale buff colour, with a purple centre; the foliage small and palmate; the plant of dwarf habit. Mr. Sherratt, gardener to J. Bateman, Esq., Knyppersley, sent a beautiful and well-cultivated specimen of Pleione lagenaria, and a special certificate was awarded it. From the Society's gardens two hybrid Coluses of great promise were awarded first-class certificates; their names were Princess Royal and Prince of Wales. A seedling variegated Fuchsia, named Regalia, was also exhibited from the Society's gardens; it has rich golden foliage, deeply veined with red; the mixture of colour has a very pleasing effect.

Mr. Church, gardener to J. Hodgson, Esq., sent seedling Variegated Pelargoniums—J. Hodgson, Golden Harvest, Golden Sovereign, Advance Guard, and Prince Arthur. The Committee unanimously agreed that it was too late in the season to judge of the merits of Zonal Pelargoniums. Mr. Walking, nurseryman, Lewisham, also sent two seedling Variegated kinds, named Miss M. Walking, a highly-coloured variety of great promise, and Viceroy of Egypt, too much like others of the Bronze Zonal section. Mr. Hill, gardener to R. Hanbury, Esq., The Peles, Ware, exhibited a fine specimen of Vanda cœrulea, which was awarded a special certificate.

Mr. Williams, of Holloway, sent a fine specimen of Aralia Sieboldi variegata, which in 1861 received a label of commendation in consideration of its great beauty and usefulness as a decorative plant, and its having proved to a certain extent hardy, surviving the last four winters in Battersea Park; the Committee decided that the label of commendation should be superseded by a first-class certificate. Mr. Williams also sent Aralia aureo-variegata, in the present condition not equal to A. Sieboldi; a second-class certificate was awarded it. A special certificate was given for his collection of Orchids.

Mr. Ford, gardener to E. Hubbard, Esq., sent a collection of seedling Zonal Pelargoniums. Mr. Parker, Nurseryman, Tooting, exhibited a beautiful specimen of Zygocotyledon Garbieri, very distinct, and a first-class certificate was awarded. Mr. Green, gardener to W. W. Saunders, Esq., exhibited a small collection of curious and interesting plants, which was awarded a special certificate.

Mr. W. Paul, Waltham Cross, sent specimens of three of his well-known seedling Zonal Pelargoniums, Red Admiral, Prince Silverwing, and Silver Swan; the latter a white-edged plant, the flowers also white.

Messrs. Veitch sent a large specimen of Ampelopsis Veitchii, a useful climber for covering a wall, having small foliage not unlike Ivy; also Ampelopsis japonica, another climbing plant, with rich foliage of bright autumnal tints; it received a first-class certificate. Mr. H. Veitch brought out specimens of Abutilon Thompsoni from the open ground, showing no injuries result after the previous night's frost, thus proving the plant anything but a stove plant, as it was first supposed to be.

Mr. Green brought specimens of bright flowers of Begonia Martynia, grown in the open ground. The Chairman announced that J. Bateman, Esq., had sent thirty seedling plants of Ribodendron javanicum for the ballot. Mr. T. D. Fish sent leaves of the true Claret Vine, the deep yet bright ruby tints of which were much admired. The introduction of these highly-coloured leaves led to a suggestion, that an interesting exhibition might be made next October by the arrangement of many plants so beautifully variegated and ornamented by their rich autumnal tints.

GENERAL MEETING.—W. Wilson Saunders, Esq., F.R.S., in the chair. One new Fellow was elected, and the Birmingham Horticultural Society admitted into union. In reporting the awards of the Fruit Committee, G. F. Wilson, Esq., F.R.S., stated with reference to Walnuts, that when these were in a half-dry state they might be made almost as sweet and plump as when fresh-gathered, by soaking them

in warm water for half an hour and then placing them for six or seven hours in salt and water.

Mr. Wilson Saunders remarked, that the frost of the previous night had nearly stopped out-door gardening. In Surrey the thermometer had fallen 11° or 12° below freezing point, and all the half hardy bedding plants had been destroyed, but on high and dry situations the frost had been so much less severe that even Dahlias had been scarcely touched. He, therefore, recommended those who wanted to preserve such plants to a late period, to choose for them situations as high and as dry as possible, and then the chances of keeping up a late display would be much greater than if the plants were otherwise placed. After noticing the variegated *Aralia Sieboldii* as a very desirable plant for winter decoration, as it had proved hardy at Battersea, Mr. Saunders referred to *Ampelopsis Veitchii* as a valuable addition to hardy climbing plants, though he would not venture to say that those who had an affection for the old English Ivy, with its glossy leaves and beautiful markings, would substitute the one for the other. The leaves of the *Claret Vine* were then pointed out as being very beautiful in colour when dying-off, but Mr. Saunders observed that those of another Vine that had been sent home from Malaga, but of which he did not then remember the name, were even more remarkable for the beauty of their colours when dying-off, being then yellow and red.

The proceedings closed with the announcement that the next meeting would take place on the 17th of November.

JERSEY AUTUMNAL FRUIT SHOW.

WEDNESDAY, October 11th, was one of those sunny autumnal days, so frequent at this season in favoured Caesarea, and on that day at two o'clock was opened the Autumnal Fruit Show of the Royal Jersey Horticultural Society. The spacious saloons of the Imperial Hotel—which, hy-the-bye, is admirably adapted for a show at this season, were crowded with the *dite* of the Island, who thronged around the tables covered with fruit of unusual excellence and beauty. The tables for the fruit measured about 150 feet in length, and 4 feet in width, literally covered with Pears, Apples, Grapes, Plums, Peaches, &c., and about 100 feet of table devoted to vegetables. What struck me forcibly was the number of varieties and the correctness with which they were named.

I will first notice the Chantmontel Pears, for which the Island is so justly celebrated. There were four classes for these—sixes, twelves, twenty-fives, and fifties, in all which classes the prizes were keenly competed for. The first prize fifty were truly magnificent fruit, of perfect shape, highly coloured, and of unusual size, as the weight—viz., 61½ lbs., demonstrates. Next came twelve Uvedale's St. Germain, here labelled Belle de Jersey, weighing 26 lbs.; twelve Pound Pears, weighing 15 lbs.; twelve Van Mons Léon le Clere, 10 lbs. 12 ozs.; twelve Beurré Clairgeau, 16 lbs.; twelve Duchesse d'Angoulême, 15 lbs. 3 ozs.; six Maréchal de Cour, 6 lbs. 2½ ozs.

The above are the few of the crowded state of the rooms enabled me to take note of the weight of, but there were fine specimens among others of the following varieties:—De Tongres, an October fruit of great beauty and first-rate flavour; General Todtleben, good; Marie Louise; Beurré d'Arenberg (strictly Glou Morceau); Bergamotte de la Pentecôte, l'Assé Colmar, Winter Nelis, Beurré de Rance, Crassane, Pengetley (February to March), Soldat Laboureur, Beurré Flou, very large, resembling Duchesse d'Angoulême; Doyenné du Comice, very large and first-rate; Graoslin, good, but thick-skinned; Spring Beurré, Groom's Princess Royal, Swan's Egg, Grosse Calabasse, Columbia. 1 lb. 4 ozs. each, a good December fruit; Forelle, Beurré Gris de Lun, very fine; Beurré Six, too green; Beurré Diel, fine; Vanquelin, Beurré Bachelier, very large and first-rate; Colmar d'Arenberg, large and fine, but second-rate, besides many others.

One exhibitor showed a collection of sixty-seven varieties of Apples, and sixty-four varieties of Pears.

Apples were not unusually fine. The varieties most esteemed seemed to be Old Pearmain, Cornish Gilliflower, Ribston Pippin, Nonpareil, Golden Russet, Royal Russet, Hammond's Pippin, a Jersey-raised variety; Hooper's Seedling, also Jersey-raised; Guernsey Pippin, Guernsey-raised; Pigconnet, Golden Pippin, Court of Wick and Lemon Pippin, much esteemed for culinary purposes on account of its long-keeping qualities.

I have refrained from giving your readers the names of the prize-winners, as this would render my communication lengthy, and they only possess a local interest; but the grower of the fifty Chantmontels, Mr. G. De Carteret, St. Peter's, and Mr. G. Thomas, the exhibitor of the collection of Apples and Pears, deserve the distinction of being named here.—*VERITAS, Turf Book, Jersey.*

SELF-SOWN PELARGONIUMS.

"A. R. C." wishes to know whether the seed of the Pelargonium has been found to sow itself in the open ground, and spring up like any common annual as it has done this year, and whether such self-sown seeds are not likely to produce more hardy plants than seeds sown under cover or than cuttings?

[This has been an uncommon year, and it has not been so

common for Pelargoniums to self-sow themselves in the open air hitherto. We are sorry to say that our previous experience tends to prove that plants so raised will not be more hardy than seedlings or cuttings of the same kinds raised under glass, and gradually hardened off. Little can be done to acclimatise in this way, but the little is worth trying, and you may be more successful than some.]

POMOLOGICAL GLEANINGS.

Nothing can show more plainly the climate that AMERICAN APPLES enjoy than the effect, on some of the choice varieties, of the past hot summer. Newtown Pippins are clear and spotless. Melon Apples are large and beautiful. Some little trees of this kind, only 2 feet in height, on English Paradise stocks, are staggering under a dozen each of very large fruit. The Washington, a very large early autumn Apple, melting like a Peach, so that the juice runs down the knife in cutting it, has also been very fine. A dozen other kinds of the American race of Apples have been equally fine. In ordinary seasons, unless in gardens in the south of England, with warm soils and aspects, these fine tender-fleshed Apples should be trained against walls or grown in orchard houses.

— "My attention was drawn to the LATE BLACK ORLEANS PLUM, a fine but neglected sort, by your mention of Sandalls Plum, which seems to be of the same race, and ripens at the same time—viz., about the middle of October. It is mentioned in the Catalogue of the Horticultural Society, 1831, but not described. It is round, sometimes a little inclining to oval, of a deep purple, with yellow flesh, and very rich and good. It is not such a wild grower as Sandalls, which forms a large tree, and comes earlier into bearing. On tasting and comparing it with the latter, it seemed a superior variety in size and flavour. Its designation in the above catalogue is 'Orleans Late or Black.' In the edition of the same catalogue for 1842, it is described as round, first quality, second size.—T. R."

— HEAT is the principal working agent in producing fruit as well as wood. We can approximate very nearly the amount of heat required to produce any given variety of Apple. Nearly all Apples blossom at or about the same time of the month in corresponding latitudes. In the latitude of Boston, the average season is near the 25th of May for the full blossom of the Apple, with a mean temperature of 51.1° Fahrenheit. The Early Harvest blossoms fall on the 25th of May, having five days to grow in the month of May. Five days multiplied by 51.1° is equal to 270.5° of heat. The mean heat of June is 62.8° × 30 days = 1,884°. Twenty-five days in July to its ripening, with a mean heat of 69.1° = 1,726.5°. By this estimate, we find that it requires about 270.5 + 1,884 + 1,726.5°

3,881° of heat to ripen the Early Harvest. The Red Astrachan and the Sweet Bough, ripening about twelve days later, require these twelve additional days of heat more than the above variety. 69.1° of mean heat by twelve days = 829.2 + 3,884° = 4,713.2° aggregate amount of heat required to ripen the Red Astrachan or Sweet Bough. The Porter ripens about the 15th of September; requires in May 270.5°, in June 1,884°, in July 2,170°, in August 2,048°, fifteen days in September 93.9° = 7,313° of heat to ripen after its time of blossoming.

— THOSE pretty fruits, POMEGRANATES, are this season ripening in the open air at Dropmore. When we were there a few days ago our veteran friend, Mr. Frost, pointed out three beautiful fruits of a fair average size, colouring well, and almost ripe, growing on a fine old plant of the double scarlet variety against a wall near one of the houses. This plant, Mr. Frost stated, flowers most profusely every season, and nearly everyone knows how handsome the flower of the Pomegranate is, and when (but is succeeded by the fruit, it is doubly interesting. There is another plant, of the single variety, growing beside this one, on which there are no fruits. It is somewhat singular, and it has been observed before, that the double variety should be the freest-fruiting. The fruits themselves are more ornamental and curious than useful, more celebrated by their name in biblical history than they are for their wonderfully fine qualities as an edible fruit. Indeed, there is very little to eat about them, or rather in them; the numerous seeds are very prettily tinged with rose, and there is a slight but agreeably sweet perfume, but for taste, after sucking the seeds, there is a strange disappointment, for there is nothing better than sugar and water. Mr. Frost had also little half-standard plants of the dwarf Pomegranate (*Punica nana*), flowering most profusely in

small pots. They are used for decoration, and are very pretty. This is the most suitable kind for the purpose.

— At the meeting of the Fruit Committee of the Royal Horticultural Society on Tuesday last, Mr. Rivers, of Sawbridge-worth, exhibited some very remarkable examples of DWARF APPLE TREES on the English Paradise stock. These varied from 18 inches to 2 feet high, but one or two slightly exceeded the latter height. For such small trees the number and size of the fruit with which they were laden was most extraordinary, and when they had been dispatched from the nurseries there were many more fruit on them, which had been shaken off in the journey, so that it was impossible to say how many really belonged to each. Mela Carla, Coe's Golden Drop, and Stamford Pippin had each from six to eight fruits, without counting the "unattached;" Calville Blanche a dozen; and the beautiful Pomme d'Api, or Lady Apple of the Americans, nineteen, and there had been several more on the tree. What advantages such small trees offer to those having but a small extent of garden ground! Not only can a large amount of excellent fruit be secured from a small space, but the number of varieties that can be grown may be multiplied from ten to twenty-fold, thus securing diversity of flavour, successional ripening, and a vastly increased amount of interest to the cultivator. The collection received, as it well merited, a special certificate.

PEACH CULTIVATION.—No. 4.

ANOTHER mode of fan-training is that given below, and it is, perhaps, the best for long pruning; the branches are also originated with greater certainty. It is not, however, by any means a common mode of training—at least not generally practised; for Peach and Nectarine trees are too often trained on no principle whatever, only an attempt is made to cover the wall with branches and bearing wood, no regard being paid to the maintenance of an equality of vigour between all the branches. It is no uncommon occurrence to find trees with all the vigour on one side or in the few upright branches, the other side or the lower branches making hardly any growth.

By this mode of training the maiden plant is cut back to two or three good eyes or buds 9 or 10 inches from the ground, and in the course of the following summer we have two vigorous shoots, all others being rubbed off. We have thus the form shown in *fig. 5*, *a a* being the two side shoots, which are brought

Fig. 5.

down to the horizontal line by degrees, but in summer trained more upright, so as to give them vigour, as is shown by the dotted lines.

In autumn the shoots *a a* should be cut back to three buds

Fig. 6.

each, and not further from their respective bases than 3 or 4 inches. From each of these shoots two others will be obtained in the following year. The tree in autumn will be as

represented in *fig. 6*. The lower two shoots, in order to give them vigour, are to be trained more upright, as shown by the dotted lines; whilst the upper two shoots are trained more horizontally, so as to keep them from appropriating all the vigour of the tree or becoming more vigorous than the lower shoots, which ought to be the strongest. Unless the ends of the lower branches were thus turned upwards in summer, and those of the upper ones depressed, the latter would grow much stronger than the former, and this ought to be guarded against.

We have now four shoots, the maiden tree by the first cutting being divided into two branches, and by the second cutting it is divided into four; and these, being cut back at the winter pruning, are to be divided into eight, as shown in *fig. 7*. The figures opposite the bars correspond to the number of the pruning or cutting-back.

Fig. 7.

The four shoots on each side of the tree being cut for the fourth time to three eyes will produce two shoots each, or in all sixteen strong shoots. The lowest of these must be encouraged by training them during the growing season in a more erect position than the shoots from the upper branches, and whatever laterals they push must be kept closely pinched back to one joint.

By autumn the shoots will be strong, and must be put in their proper position on the wall. This will be done by drawing a semicircular line, taking as a centre the height of the lowest branches from the ground, and the centre of the stem at that height; then with a line 5 feet long describe the dotted line *a b*, *fig. 8*, and divide this into 1-foot distances, calculating from the lowest branches on each side, which should be 1 foot from the ground. This will give to the whole sixteen shoots a distance, where they cross the dotted line, of 1 foot each, and that number of shoots or branches will entirely cover the wall within the radius *a b*. These shoots will need to be trained straight for the divisional parts on the dotted lines, calculating from the lowest shoot on each side and then upwards, training each directly to its corresponding number of the divisional parts on the dotted line, shown to the left of *fig. 8*, from 1 to 8.

In autumn the shoots, if of equal vigour, will not need to be shortened farther than to secure for each a strong leader. This shortening, as to extent, will be determined by their strength. If strong, their length may be shortened one-third; if moderately strong, one-half; or if weak two-thirds, always cutting to a wood bud, or to a triple bud which will have two fruit buds, one on each side of the central one—a wood bud.

In the following spring the shoots pushing from those shortened will need to be regulated. One shoot must be trained from the end of each as a continuation of the shoot or branch, and below it others a foot apart along the branch, commencing at 6 inches from the rise of the branch. Take out the points of all other shoots at the second or third joint, and keep them closely pinched back to one joint throughout the season, all foreright shoots or breastwood being disbudded or rubbed off closely. The shoots left at 1 foot apart are not to be stopped until they have grown 10 inches, then take out their points, and stop all laterals at the first joint. The leading shoots must not be stopped unless they grow too vigorously, or more vigorously than the corresponding shoots on the opposite side; then by stopping and keeping closely pinched, also by depressing the over-vigorous shoots, a proper balance of vigour may be secured. The lowest shoots should, if anything, be more vigorous than the upper leading shoots; they must therefore have their extremities raised if inclined to grow less vigorously than the upper shoots, which, on the contrary, must be depressed.

When the shoots reach the semicircular line (for their annual treatment in respect of training does not vary from that of the previous year until they reach the dotted line), another leading

shoot or branch should be originated. This will be understood on reference to *fig. 8*. Each leading branch is to be there subdivided into two. An arc, *c d*, 20 feet in diameter, must then be described from the same centre as the first, with a line

10 feet in length. This is to be divided into 1-foot distances, commencing from the lower branches, and there will be twice the number of divisions. By the dividing of the branches the wall will be furnished with branches at 1 foot apart. When

Fig. 8.

the branches are fully 1 foot from each other bearing shoots must be left on the under as well as the upper side of the

branches. The tree when full grown will appear as represented on the right of *fig. 8*.—G. ABBEY.

WORK FOR THE WEEK.

KITCHEN GARDEN.

ALL crops for winter storing should now be out of the ground and carefully packed in sheds, outhouses, and cellars. They will require to be looked over from time to time to see that there is no dampness amongst them. Onions are apt to rot about this time if too close together. When the ground becomes a little dry on the surface see that it is stirred among young crops of Winter Spinach, Onions, Lettuces, Endive, &c., and cut off any decayed leaves. If you are in the habit of mulching your beds of *Artichokes*, take care not to do more harm than good by covering the ground when it is too wet. Any time between this and Christmas will do when the ground is quite dry, and when it is in this state you may give a good earthing-up to the *Celery*; it will help to keep the frost from the plants. I would advise that *Shallots* and *Garlic* be planted now as a preventive against maggots. Some writers have maintained that the absence of all animal manures is the great secret, and that the bulbs can be safely planted in February or March if you choose for them a light rich border which has not been manured for a year or two; but when they are planted in the autumn they begin to form roots immediately, which extend widely before the tops begin to grow in the spring. There is then a great command of nourishment provided for the leaves as soon as they are ready to receive it. It is of great importance in the cultivation of all bulbs to let them, if possible, make a large portion of their roots before their leaves are excited. Again, when *Shallots* are planted out in the spring their roots and tops begin to grow simultaneously, and it sometimes happens that several weeks of favourable weather are then experienced, and the leaves in that case grow more rapidly than the roots, and exhaust the resources of the bulb faster than the roots can make up the deficiency.

FRUIT GARDEN.

I would urge the importance of early-autumn planting. If put off till December scarcely any advantage is gained over planting in March or April, but a great disadvantage will be experienced if severe weather should set in immediately afterwards. If the leaves are still somewhat greenish the check given by raising the plants will have a tendency to accelerate

the ripening of the wood; and if, after watering, the bark of the young wood shoots should present any appearance of shrivelling, hay or straw bands may be twisted round the stems of the trees, and the tops slightly shaded for a few days with fronds of Fern, &c. The straw bands should be twisted hard; and for tender trees they will be serviceable in moderating the rays of the sun in summer and in checking the severity of frost in winter. If, in addition, the roots are well mulched with dry litter they will grow all winter, and thus be well fitted to supply the expanding buds in spring. In many gardens the replacing of the old trees should be gradually effected. I say gradually, because frequently gardeners get themselves into trouble by clearing away too much at a time, and thus rendering the supply deficient until their young trees come into bearing. In planting care should be taken to select the most approved varieties. The improved varieties of Pears should be introduced into every garden either by planting or by grafting on established trees. In addition to their other good qualities most of them are great bearers and produce fruit when the trees are comparatively young. Such sorts are Marie Louise, Dunmore, Louise Bonne of Jersey, Duchesse d'Angoulême, Althorp Crasanne, Glon Morceau, Knight's Menarch, Passe Colmar, Ne Plus Menris. These will supply the table with delicious fruit from September to the end of February, and in places at all favourable will succeed admirably as standards. The Easter Beurré and Beurré de Rance will furnish a supply until May, and even later if the fruit be preserved in jars. Both sorts will thrive in most places as standards, but well deserve an east or west wall. No Pears need be grown in favourable places on a south wall, with the exception, perhaps, of a Jargonelle to supply early fruit. This, along with the Citron des Carmes and one or two more varieties, will be quite sufficient for an early supply.

FLOWER GARDEN.

Those plants which require protection from frost through the winter should now have the framework of the protective structure put on, to be ready for immediate use in case of a change of weather. Mats are generally used for this purpose, but a good covering of reed or straw is preferable to them, and

not nearly so expensive. Plants in borders, such as tender *Lobelias*, *Tigridias*, &c., should be removed to a back shed and covered with sifted ashes or old tan, or the *Tigridias* may be placed thinly under the greenhouse stage. *Fuchsias* and *Salvias* in beds, if it is not intended to take them up, should have their roots covered with a thickness of 6 or 8 inches of dry peat earth or leaf mould, which in ordinary winters is quite sufficient for their preservation. *Fuchsias* more than almost any other plant deserve proper protection through the winter, for they make magnificent autumnal beds. Should the weather prove favourable the main bed of *Tulips* may be planted, though, in fact, any time between now and the second week in November will do. Where plants of *Polyanthuses* have been permitted to make three or four crowns standing high out of the ground (which they will do if not divided yearly), emitting from the neck of the plant roots that have assumed a green tint by exposure to the air—these, if worth the trouble, should be parted and reset without delay. *Anniculas* may now be placed where they are to winter. If protected by frames these should have bricks placed at each corner so as to raise them from the ground, to allow at all times a free circulation of air amongst the pots. Though *Pansies* when properly managed are seldom affected by cold, still beds of choice sorts intended for next year's blooming will be the better of having hoops stretched over them, on which mats may be thrown either in very wet or severe weather.

GREENHOUSE AND CONSERVATORY.

We must suppose the greenhouse now filled with all kinds of plants suited for nearly the same mode of culture. These ought to have as much air as the house and the state of the weather will permit. The inside should be kept as dry as possible, and the watering should be done early in the day. No plants should receive more water than is absolutely necessary, and the whole ought to be tidy, orderly, and free from dead leaves, insects, &c. The *Chrysanthemums* will have a superiority in the conservatory for some time, and well do they deserve it. The climbers must now be very gradually pruned as they go out of flower so as not to make any part too naked at once, and if the work is finished five weeks hence it will be time enough. Keep the house rather dry and close for the rest of the season.

PITS AND FRAMES.

These, now crammed with half-hardy plants, require the common routine of keeping them clean, sweet, and dry; even the night dews had better be kept from the plants after this time, but have the lights off all day when it does not rain. Close confinement is injurious to these plants at all seasons, and more so now when they are newly brought in from the open air. *Iridaceæ* require very little water after the first dose when they were potted until they appear above ground, and *Oxalises* and all bulbs newly potted require the same treatment. —W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

Weeds.—Took the chance of dry days in the end of the week to run the Dutch hoe through all ground to which access could be had, as weeds were beginning to show after the rains, where not a vestige could be seen a few weeks ago. Used in time there is nothing like the Dutch hoe for destroying such weeds, when assisted with a few hours of bright sun. It is astonishing how long the seeds of weeds will preserve their vitality. We have been careful for years in preventing annual weeds from seeding, even when we could not well hoe, sending a lad with a basket to pull up Groundsel before the blooms opened; and yet after such hot weather and the warm showers we lately had, there will be no want of young plants coming up to prevent us ever arriving at that condition when we shall have to consider what we shall have to do by way of finding work. This season, for a fortnight, we could see clouds of Thistle down, and this, with the winged seeds of the Groundsel, will furnish occupation for weed-destroyers for many years to come. But for bird seed-eaters the case would be much worse. In many cases Thistles were cut down after the seed was dispersed. If cut before the plants bloomed, there would have been a better chance of injuring the old plant, at any rate the seeds would not have been carried into other people's ground. Cutting Thistles when young will at last destroy them; the root perishes when the top is not allowed to grow. Not long ago we saw a man laboriously digging and forking-up the huge roots of the Cowthistle, when the same object would have been attained by cutting the plant with a spud or hoe an inch or so below the surface. Some years ago we had a crop of this undesirable

weed, and among all crops, and it must either have been sown or waited to us from a considerable distance, as we could not find any plants in the immediate neighbourhood. Like the Groundsel, it seeds so quickly that it required two seasons to get rid of it, and we do not wish to see it again. It would well pay most counties to have an inspector of winged seed weeds, with the power to fine those who, choosing thus to injure themselves, also inflict a great injury on their neighbours. All seed weeds when allowed to reach the seeding state should, if possible, be burned. We have subjected Groundsel and Thistles to a burning heat from fermenting short grass, hot enough one would suppose to destroy the vitality of every seed; yet from the soil ultimately left from such a heap we have had multitudes of seedlings of these weeds. We could not have believed it if we had not carefully made the experiment. If such weeds with seeds on them are taken to the general rubbish heap the seeds will be brought back to the garden comparatively uninjured—that is, if such rubbish heaps are returned to the garden, as they generally are.

Cauliflowers.—Protected with their own leaves those coming in for use. Took up good strong plants with balls that had been planted or pricked out thickly, and transferred them to an earth pit, where protection can be afforded. If we can keep vermin away, these will be useful in winter and spring. Planted out small plants under hand-lights to stand the winter, having previously well dug, and turned, re-turned, and mellowed the soil. We put five plants of the largest into a hand-light to come in first, and for the bulk put in nine plants in each light, which will be thinned in spring to four or five plants. We generally leave five, as in earthing-up the four outside ones can be bent outwards to give the centre plant more room. We will either pot or prick out in a bed, or by the side of a wall, more to succeed those in glasses. We shall keep the tops of the glasses on for a few days, and then expose the plants fully until cold weather comes. Before planting we covered the soil within each light with rough road drift; this helps to keep the plants from damping-off in winter, and none of the slimy fraternity like crawling over such a rough, prickly surface.

Lettuce and Endive.—Tied up large plants in a dry day. If tied rather tightly across the top, the wet cannot well find its way in. Ten days before being wanted is a good time for such an operation. Slates, tiles, or boards laid over the plants do admirably for blanching Endive. Even straw or dry leaves do admirably, only rains will pass through and be apt to rot the blanched part. A few dry leaves, with a waterproofed covering, do well. We must soon raise some plants, and place them under protection; but we hope there will be no frost to injure them as yet. Hoed among young plantations, and planted out more by the side of fences, and on sloping banks, to come in in spring. Planted out a couple of rows of small plants of *Cos* Lettuce in front of the latest orchard house, as from the same place we had an invaluable supply last spring, before we could put them out of doors. Rather singular to say, the most exposed ground is more liable to the ravages of grubs than where it is more sheltered. On the open ground we have had to examine for grubs, and fill up frequently. Where we have planted several rows near a wall, not a plant has been touched.

Celery.—Earthed up a bed, after watering it well at bottom the day before. We shall want it in the beginning of November and later. What we have will last until then. We shall ere long earth up all our earliest, and will encourage the latest to grow until we have signs of frost.

Now is a good time to decide on the rotation of cropping, and for trenching, ridging-up, or digging all spare ground. As yet we have not a piece in fallow.

FRUIT GARDEN.

Much the same as last week. We have not quite housed all our fruit, and the quantity we obtain from low bush trees is astonishing. Some years ago we planted some common standards of Apples and Pears as a little orchard, but we rarely obtain anything from them, though generally the trees look well at this season, but the place is close to the farm, and some of the sheds being thatched, such clouds of birds visit these trees in the spring that not a fruit is left, and in some extreme cases the wood buds are so picked out that the trees make few leaves in the first part of the season. The low bush trees round the borders of the kitchen garden would share a similar fate, only the workmen help to keep the birds away, and a colouring of limewash early in spring helps to protect from the birds. We find this a great safeguard to the trees, and it is easily afforded these dwarfs. Had we our way, we would have some quarters of dwarf Apple, Pear, Plum, and Cherry trees. Nothing

would pay better, and it would be easy to protect them from early frosts and the attacks of birds. Some have wished we would give the size of a few of our trees, and the measure or weight of fruit obtained from them, but it is always unpleasant to do such things when the least suspicion can be created as to over-statements.

To all amateurs and the possessors of small gardens, growing trees in the bush or pyramidal style has this great advantage—that the trees can be examined, and have all that is necessary done without the operator needing to leave the solid earth, and steps and ladders are always inconvenient to those not used to them.

The next three weeks will be the best time for preparing and planting all such dwarfs. For first and ultimate economy no plan is better than station-planting. The spaces for each tree may be 4 feet to 6 feet square, or in diameter. In all cold clay soils it would be well to concrete the bottom for such a space, having that at least 15 inches below the surface, and the earth raised above it other 15 inches, but which will gradually sink. In planting, if the young trees have a tap root, either cut it off or bend it outwards, and the other roots should be neatly packed as much horizontally as possible, and from 6 to 8 inches from the surface. The chief use of concreting, or placing a flag-stone immediately beneath the tree, is that the tap roots cannot well go down, and if the tree grows too vigorously at first the roots can be cut as they extend beyond the concreting. Many would like to have these neat little fruitful trees, however, who do not see their way to obtaining stones, lime, and gravel to make bottoms for the trees; and for their encouragement we would say they can succeed very well without them. Such stations may be made a little larger and well trenched, and the subsoil well stirred, but left at the bottom. Then borrow enough from the neighbouring soil, if at all good, or a little fresh soil if to be had, so as to raise the centre of the stations fully 18 inches above the neighbouring ground; plant as above stated, and secure with a stake, and then mulch over with rotten dung—a much better plan than mixing the dung with the soil.

If you obtain an early crop you may never need to resort to root-pruning; but if the tree become too strong you will require to cut the roots that run downwards, and the more horizontal ones will then take the growth. Two things will ensure success. A good crop will lessen mere luxuriance of growth, and if the roots are encouraged to keep near the surface they will have less inducement to run downwards. The chief attraction to go down is to obtain moisture. Let the trees have that at the top, and the inducement is removed; and the simplest way to give them this requisite is to mulch during summer with rotten dung, however thin the covering. All extra nourishment we would thus give from the surface. We just reverse the plan we would pursue if our object were the greatest amount of timber in a specified time. We do not here want timber so much as the greatest amount of eatable fruit in a small space, and therefore the more the nourishment, and the more the moisture absorbed by the roots is thoroughly oxygenated by free access of the air, the greater the fruitfulness of the plant. Allow a tree to grow a little freely at first to form itself, arrest mere growth by root-cutting or a heavy crop, and then entice the roots to keep near the surface by a little manuring on the surface, and such trees will bear heavily for years without needing any root-pruning, and no great amount of top-pruning, except a little pinching and nipping of the summer shoots in summer. Orchards are all very well, but these little fruitful trees will afford continual interest to the enthusiastic amateur, and even a lady can do all the work they need, except, perhaps, giving a barrowload of dung to two or three trees when young, and a barrowload to each when well established.

One circumstance, so far as we know, has militated against their more frequent use, and that is something like a dread and a hazy conception of the necessity of root-pruning. Now, frequently there need be none at all. Plant on raised platforms, plant shallow, give surface-waterings if necessary, keep the roots near the surface by mulching, and yet, by deep stirring at first where there is no concreting, allow the surplus water to pass freely where there is no regular draining; obtain a good crop, and keep the roots near the surface as above, and you may never need to cut a root. If necessary, however, to arrest growth, it is just as simple to cut a strong leading root as it is to cut or stop an over-luxuriant shoot, and thus obtain from that which otherwise would have produced nothing but wood buds and mere strong shoots, several shoots that would produce fruit buds. In a few words, had we our will, and gar-

dening to commence, we would have all our fruit trees in small compass and thoroughly under command; and as we delight to see the possessors of small gardens acting on this principle, and would delight still more to see, in many such gardens, the huge Apple trees that now shade the ground devoted to vegetables exchanged for our favourite dwarfs, we would wish all aspirants to success in this direction just to bear in mind a simple fact, to which we believe we were the first to draw prominent attention—that the deeper the roots go, and the richer the material on which they feed, the greater will be the bulk of timber produced by the tree; whilst, on the other hand, the nearer the roots are kept to the surface, the more nourishment is given from the surface, the more the moisture and the nutriment is thus in contact with air, the more shall we promote the fruiting, and so far discourage the mere growing and extending processes. It would be easy to make a tree all fruit and but little growth; but that is not pleasing even to the eye, and a certain amount of vigour is necessary to keep the tree continuously fruitful, as well as to give size to the fruit. What we contend for is, that all that can be given, not by digging-in manure, but by applying it to the surface. Do not be driven from such a simple proceeding by being laughed at for thus wasting the little manure you give. "Why," says an elbow friend, "you are as great a spendthrift as Mr. Wuzle there, who carts out his manure for Turnips and Cabbages, and lets it become as dry as hay before he covers it in." Well, not quite. For all mere bulk of produce the manure cannot be too soon covered up from the air and its wasting decomposing powers; but our practice may well be different when we aim at obtaining flowers, seeds, and fruit, and not mere bulk of roots and leaves. If we wished to obtain the largest Cabbages we would dung well, stir the ground, water—do everything to encourage growth. If we wished a Cabbage plant to flower as soon as possible we would give no manure, keep the soil about it hard—in fact, encourage the throwing-up of the flower stalk instead of abundance of succulent leaves. We wish our small fruit trees to bear fruit and yet have enough of growth to continue fruitful, and therefore we prefer manuring chiefly from the surface. We adopt the same plan with flower-garden plants frequently. If we enriched the beds and manured deeply we would have too vigorous growth to ensure free blooming. By giving a little help to growth, and then surface-manuring, we secure enough of growth and free-blooming, whilst otherwise we would have too much growth and too few flowers.

ORNAMENTAL DEPARTMENT.

Never did we see the lawns more rich and beautiful. The drought destroyed many of the weeds, and the grass looks all the more beautiful without them. After the rains very little rolling is necessary to keep them smooth, and for this purpose under such circumstances nothing is better or more easily applied than a wooden roller with a light handle—say the roller a foot in diameter, and from 3½ to 4½ feet in length, as then a lad can easily go over a large piece of ground. When mowing has to be done a day or two afterwards, such a light roller is better than a heavy one, and it always leaves the gloss and polish of a fresh-ironed garment behind it.

We have had a few slight frosts, but with us neither Coleus, Perilla, nor Heliotrope, is greatly injured, and we are unwilling as yet to take up some small favourite plants, and a few large ones for the centres of beds next season. We must keep watch, and only hope that the first sudden frost will not come on a Sunday evening.

Took in most tender plants in pots under glass, or under protection, as what is in pots will suffer more easily than what is growing in the ground. Some plants, as Salvias, are quite a thicket of bloom, and the beds in general, though not brilliant, are still fair.

As to propagating, we have made a commencement with Calceolarias. As previously described, our pit is too deep for our purpose. We therefore put some dry litter in the bottom, a few leaves on the top, and trod firm; next a couple of inches of half-rotten leaf mould, mixed with a little lime; then 3 inches of soil, fresh sandy loam, the roughest riddlings at bottom, the finest at the top, well trod, and levelled, and then a quarter of an inch of road drift sand, and in that placed the cuttings in rows 2 inches apart, and 1 inch from cutting to cutting in the row.—R. F.

TRADE CATALOGUE RECEIVED.

William Chater, Saffron Walden.—*Catalogue of Hollyhocks and Roses.*

COVENT GARDEN MARKET.—OCTOBER 21.

THE cold weather has somewhat checked our supplies, but prices have not advanced. A fair amount of business has been done during the past week, and we may look forward to some improvement. Dutch Hamburgh Grapes are still very good, and good samples of hothouse Grapes are easily to be obtained; out-door Grapes have also been well-ripened this season.

TO CORRESPONDENTS.

.. We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c.*, 171, Fleet Street, London, E.C.

CYCLAMEN CULTURE (*Edmund*).—In Nos. 297, 298, and 299 a full detail is given. You can have them free by post from our office if you enclose twelve postage stamps with your address. You can also have "In-door Gardening" and "Out-door Gardening" for forty postage stamps. They contain a full calendar for every week in the year.

REMOVING TREES (*G. H.*).—You cannot legally remove the fruit trees; but as you say "the landlord does not oppose" the removal, why ask the question? If you merely mean that he does not know you wish to remove them, you had better ask his permission.

TRICOLOR PELARGONIUM CUT DOWN (*J. M.*).—The Tricolor Pelargonium will very likely break, but not so freely as it would have done had the top remained on it. If the top exhibits any symptoms of variegation, if the cutting is struck it will be sure to throw out variegated breaks. Even if there is no sign of variegation, it may throw off variegated breaks towards the middle or end of next summer, if the plant from which the top has been taken shows any variegation at the base.

PEARS AS PYRAMIDS (*An Amateur*).—As you wish to grow your Pear trees in the pyramid form, procure them grafted on the Quince. By this way you will have good specimens of the varieties you mention. The Morello Cherry budded on the Malahob makes a pretty tree, and produces splendid fruit.

BLACK HAMBURGH GRAPES (*Kate*).—The bunch of Black Hamburgh Grapes you have sent is of excellent quality, and the flavour of the berries is very good.

GLADIOLUS SPAWN (*An Old Subscriber*).—The spawn about the size of peas may be taken up, dried, stored in dry sand, and kept in a dry cool place free from frost until planting time in March. Or the spawn, on taking up, may be potted in small pots, plunging these in a cold pit in coal ashes, and keeping them dry and from frost over winter. We think the latter the better plan.

SHEFFIELD (*Fair Play*).—We are very glad that you find Sheffield is not "the horribly dusty and smoke-begrimed place," which Mr. Willis represented it to be; and we shall be very pleased to insert a communication showing how well plants can be made to grow there, but we cannot spare a column merely to testify that Sheffield is not so smoky and dirty as are Manchester and the Staffordshire Potteries.

PELARGONIUM CUTTINGS (*J. G. D.*).—Cuttings strike more safely and speedily if inserted round the sides of the pots than when placed in the centre. The cuttings when struck succeed better potted-off in small pots; and when these are full of roots repotting in others of larger size as often as the roots fill the pots, will produce fine plants. Only a small shift should be given each time. The plants and cuttings taken into your sitting-room will winter more safely if potted in sandy poor soil rather than in rich compost. They should be kept dry, no water being given so long as the leaves keep from flagging, and in spring when they begin to grow repot in richer compost, and encourage with liberal waterings. It is not advisable to encourage growth in winter, for that is their

period of rest. To insure bushy plants you must stop them in spring when they begin to grow, or cut them down to within 3 or 4 inches of the soil, though the plants are better if merely the points of the shoots are taken out when they are young to induce the production of side shoots near the soil.

SOWING PELARGONIUM SEED (*E. McDonnell*).—Having no better place than a small frame which you can place in a south window, you will not do any good by sowing the seed now, but will probably lose the plants from damp in winter. We advise you to sow the seed next March, in a small pot—say, 6 inches in diameter, or one that the glass will cover, and place the seed-pot in a pot of larger size, filling up with crocks so as to bring the rims to one level. Fill the space between the pots with small crocks, and at the top with silver sand. The glass should then be set on the sand between the pots, and the soil being kept moist the plants will soon appear. To keep them dwarf they must have air by raising the glass a little on one side, increasing the opening as the plants increase in growth, and removing the glass by degrees. This will give you plants earlier than by sowing in the frame out of doors; indeed, by sowing in the window the plants will be fit to pot-off by the time the seed should be sown in the frame—namely, in May.

WINTERING VARIEGATED PELARGONIUMS IN AN OUTHOUSE (*E. M. B.*).—Your house will answer for wintering all the Pelargoniums you name, except Cloth of Gold, which we fear will not winter safely. The plants should have poor light soil, and no water should be given except a little occasionally to keep the wood from shrivelling. In mild weather and fine days open the doors wide, but shut up before the air becomes cold. It would be very desirable to hang in front of the plants mats from the roof to the ground when severe weather occurs. The plants should not be taken out until May; but when they begin to grow they ought to be placed nearer the door and have water, increasing it in proportion to the growth. The door should be open, after the plants begin to grow, whenever the atmosphere is not frosty, for they must then have light and air.

SHRUBS AND TREES FOR A SHREBBERY (*Belinda*).—We suppose you wish for evergreen shrubs, and we recommend *Aucuba japonica*, *Berberis aquifolium*, *Berberis Darwini*, *Cotoneaster Simonsii*, *Ilex ferax* (gold and silver variegated), *I. balearica*, *I. angustifolia*, and the gold and silver-edged Hollies, Double-blossomed *Furze*, and *Viburnum tinus*. Of trees, such as *Pines*, have *Pinus austriaca* (the best of all for shelter), *P. conabra*, and *P. excelsa*; *Juniperus virginiana*, *J. chinensis*, *Cupressus Lawsoniana*, *Thujopsis borealis*, *Thuja Lobbi*, *T. plicata*, *Taxus adpressa*, *T. baccata fructu-luteo*, and *Abies Douglasii*. If you wish for deciduous shrubs or trees we shall be glad to assist you.

SELECT CAMELLIAS, HEATHS, AND EPACRIS (*Subscriber*).—*Camellias*: *Alba plena*, *Augustina superba*, *Carlotta Papudoff*, *Benneyi*, *Fimbriata*, *La Pace*, *Leopold I.*, *Perfection*, *Mrs. Cope*, *Prince Frederick William*, *Storyi*, and *Valtearedo*. *Heaths*: *Hymenalis*, *McNabiana superba*, *Massoni major*, *Wilmorei superba*, *Scabriscula*, *Rubracalyx*, *Sprengelii*, *Shannoniana*, *Hybrida*, *Fairriana*, *Gracilis vernalis*, and *Andromedaeflora*. These will be likely to serve your purpose. *Epacris*: *Lady Penmore*, *Rubella*, *Viscountess Hill*, *The Bride*, *Hyacinthiflora*, and *Grandiflora rubra*. Other plants for winter and spring blooming are *Correa Brilliant*, *Speciosa major*, and *Harrisii*; *Cytisus racemosus*, *Coronilla glauca*, *Cyclamen persicum*, *C. Atkinsi*, and *C. eum*; *Acacia armata*, *oleifolia elegans*, *longiflora magnifica*, and *Drummondii*; *Lilium Macraei* and *L. trigynum*; *Epiphyllum Russellianum* and *E. truncatum*; *Luculia gratissima*, *Monochæton ensiferum*, and you can hardly dispense with *Azaleas* and bulbs, as *Hyacinths*, *Narcissus*, *Tulips*, and such plants as *Dicentra spectabilis*, and *Deutzia gracilis*. Nothing can be finer for spring than *Rhododendrons*; they are very easily forced, and are very useful for planting out afterwards in the borders.

LUCERNE CULTURE (*An Amateur*).—It may be sown in April, in drills 1 foot apart, in clean, well-manured ground, and should be kept clean and well manured. It succeeds best on dry, sandy, or calcareous soils. Guano water would suit it, providing you give good soakings. It may be cut twice or thrice the first year, but is not in perfection until the second year, when it may be cut four or five times. It will last many years if well-manured after cutting.

MILDEW ON ROSES (*Idem*).—We never knew vitriolised water (blue vitriol, or sulphate of copper), to fail. We know of no other remedy beyond dusting with flowers of sulphur the parts affected, keeping the plants well fed with bone dust, superphosphate, and dung, and well supplied with water in dry weather, both as to the roots and foliage.

DWARF PEAS (*Idem*).—The best very dwarf Peas are *Advancer*, *Bishop's Long-podded*, and *Yorkshire Hero*.

STONE-MASON'S CHIPS FOR FERNS (*C. T. P.*).—The sand and waste from the stone-masons will do for mixing with the compost for large, and also small-growing Ferns.

SCALE ON AZALEAS—WINTER-DRESSING PEACH TREES AND VINES (*J. B.*).—The compound you name is not safe to apply to Azaleas, but you may destroy the scale by syringing or dipping the plants in a solution of Clarke's insect-destroying compound, 2 ozs. to the gallon, and at the same strength it will be a good dressing for your Peach trees, also Vines. Though this is the proper strength for plants in leaf, it may as a winter dressing be used stronger—say 3 ozs. to the gallon, and is then safe, and better than the customary coating with sulphur, &c. It will not injure the buds or eyes.

REMOVING VINE LEAVES (*Idem*).—You must not remove the leaves until they are yellow or brown, and have begun to fall. They may then be removed. Bear with the Vines, cleaning the house, however, as well as you can for the reception of the plants. It is very desirable to clean the house before the plants are housed. It is necessary the Vines should go to rest of their own accord. The foliage is of value to them so long as there is greenness in it. It is a month or more too soon to remove it.

GRAPES SHANKING (*W. H. L.*).—The bunches have shanked. This is usually caused by a deficiency of sap, and that may be occasioned by the roots being deep and in a cold wet border. The want of a sufficiency of foliage also tends to cause shanking. We know of no remedy except securing efficient drainage of the border, and the encouraging of more foliage, which will give a more healthy root action, and a more plentiful supply of sap.

PRUNING BLACK CURRENT BUSHES (*Burton*).—In pruning the old wood should be cut out, leaving sufficient bearing wood, and the young shoots will, therefore, be encouraged, and these give the finest fruit, but unless

they are shortened the bushes become bare; to rectify which the long young shoots should be shortened about one-third their length generally, but if you wish for shoots from the base of the bush they must be shortened two-thirds, and if very close together they will require thinning. Keep them dwarf and plentifully furnished with young wood, but not very close together.

POTTING ZONAL PELARGONIUMS (*Idem*).—Your Pelargoniums, hard-cut for cuttings, would be all the better of being potted when they have made young shoots an inch or two long. The pots should not be larger than those in which the plants have been growing, but, if anything, of less size. The old soil should be picked away, and good drainage, fresh compost, and clean small pots would make your plants more healthy than they would be in the old soil and larger pots; besides, they will be in fine condition to put into their blooming-pots in spring, potting them then with the ball entire. If left over winter as they are you must in spring disroot, and some delay will be the consequence.

PEACH AND PLUM TREES UNFRUITFUL (*A Young Gardener*).—The slate coping from its drip on the Peach tree will be more injurious than beneficial. The water ought to be conveyed off, and not allowed to drip on the tree. From the wood drying back we should think the soil wet, and the roots deep. We would advise you to take up the tree carefully and replant it, keeping the roots near the surface. It should be done as soon as the leaves begin to fall. The Plum tree we would treat in the same way. Syringing the Peach tree whilst in blossom with sulphur and tobacco water, would be injurious to the blossom if the mixture were strong, but not if the petals had begun to fall and the tobacco water were used weak, that of the shops being diluted with six times its bulk of water.

WINTERING BEDDING PELARGONIUMS (*Idem*).—Your old plants should, if you can afford space, be potted singly, but if they are at present in pots no good would result from potting them now unless they were in large pots, in which case they may be turned out of the pots and put into those of smaller size, the old soil being in a great measure removed and fresh employed. The plants in this way will be wintered in less room, and will be all the better of being transferred to larger pots in spring, cutting them down and inserting the parts taken off as cuttings. These will strike freely in a gentle heat, and will be very useful, especially as you are short of young plants. They will be good plants by bedding-out time, and excellent for mixing with old plants.

WINTERING CALLAS (*Idem*).—The Callas should have a light airy situation in your greenhouse, and sufficient water should be given to keep the soil moist and prevent the leaves flagging. It is not necessary in winter to set the pots in saucers full of water, though desirable when the plants are in active growth and the weather hot. They ought not now to be repotted. Repot in spring when they begin to grow.

REPOTTING ORANGE TREES (*An Old Subscriber*).—The best time to repot Orange trees is at the end of February or beginning of March, and in doing so remove as much of the old soil as possible without injuring the roots, and afford good drainage to the new pot. As your tree has the branches partly naked, it may be cut-in a few days after potting, and if you can give it a temperature of from 50° to 55° at night, and a moist atmosphere for six or eight weeks it will push freely, and speedily make a fine plant. The Orange bears cutting well.

VALLOTA PURPUREA AND EUPHARIS AMAZONICA NOT FLOWERING (*Idem*).—Keep your plants dry during the winter, giving no more water than sufficient to keep the foliage tolerably fresh; though they droop a little no harm will result. Afford all the light possible. Keep the drainage free, but do not repot, for the plants flower best when the roots are confined. When the plants commence growing freely, encourage them with an abundant supply of water, and weak liquid manure once or twice a-week, and having secured a good growth expose them fully to light and air on a shelf near the glass, and lessen the supply of water, merely giving enough to keep the foliage from flagging. When the spikes appear water plentifully to insure their development, also when they are in flower. The first requires a greenhouse, and the Eupharis a cool stove temperature.

POTTING LILIUM LANCEOLIFOLIUM (*Idem*).—As soon as the leaves fall and the stems are yellow, it is time to repot. They will stand the winter if plunged in coal ashes, and protected from frost by a covering of litter varying in thickness according to the severity of the weather, removing it in mild periods. Myrtles may be wintered safely in an orchard house, the pots being plunged, and the soil kept dry, and a mat wrapped round them in very severe weather, not removing it until the frost is completely gone.

TRICOLOR PELARGONIUM FREAKS (*Tithania*).—Remove the preternatural white excrescences from the stems of your Tricolors at once; they only weaken the plants, and will, if allowed to remain, soon injure their health.

SEEDS OF RICINUS (*Idem*).—Allow the plant to die down and the seeds to remain in the husks. These should be kept in a dry place during the winter.

VINES IN AN ORCHARD HOUSE (*J. G. H. Amateur*).—There can be no question that by having a glass division in your orchard house you can, merely by different management as respects ventilation, keep that part warmer than the other. By moving the glass end at the north for this purpose, and having a brick end there instead, you will also make your house warmer at the loss of so much light. As to the question of heat, you are right; but we do not think you will obtain early Grapes against that wall after your twelve Vines have taken possession of the 12 feet length of the span-roofed house. When that is the case we think very little direct sunlight will fall on this wall—that is, if the Vines go up near the apex of the roof. If a space were left there Vines against the wall would do well, but then a part of the roof would be lost. We would chiefly value your wall for the greater warmth it would give. It will not look so well as the glass.

VINES IN A GREENHOUSE (*E. W.*).—You can have Vines in your greenhouse without being interfered with by your bedding plants, if you force the Vines little or not at all. The lean-to form, with a stage at back and a wide shelf in front, will be as useful as any, with the heating medium below that shelf. As you wish to have no border in front to interfere with your lawn, you might keep your pipes nearer the passage, plant your Vines close to the front wall inside, and allow the roots to run inside, where a border would be made for them; and if the front wall were on arches or piers the roots could also go out beneath the lawn, and good soil could be obtained for them and the turf replaced. This would do

admirably for Vines not to be forced. On the plan proposed your other best mode is to make the border inside the house, obtain strong long-rod Vines, plant them against the back wall, and as they grow train them down the roof. In such a case, with plants, &c., on the stage, they will do little good till they are near the top of the back wall; and therefore when planting, the buds might be nipped out, except two or three near the top of the cane or shoot.

HEATING A SMALL GREENHOUSE (*J. D.*).—For such a small house as yours we think a good-sized paraffin lamp would keep out frost; but we are afraid of explosions, and we fear that the products of combustion would injure the plants, unless you had a large concave reflector of tin suspended over the glass funnel, and a hole in the upper end connected with a small gas pipe going into the open air. A tube from a quarter to three-eighths of an inch diameter would do for this purpose, and the pipe when passing outside could be bent down to prevent the external air acting on the burner to any extent. Paraffin gives a clear light and a strong heat, but even in a sitting-room the fumes that escape become oppressive unless fresh air is admitted to the room once or twice in the evening. If you have any doubts as to the paraffin you need have none as respects a small iron stove, and you would require only a small iron funnel from it to the open air. A friend of ours, who disliked the trouble of lighting a small stove, had a small pipe placed at top instead of a funnel, and put a good-sized lamp inside the stove, and it gives to the stove all the heat he wants.

FLUE IN A VINERY (*J. K. L.*).—Order the "Vine Manual," which you can have from our office by post for thirty-two postage stamps. The best bricks make the best flues, and should be well set with lime putty. We prefer they should have no plastering inside, but be roughly plastered or heavily limewashed outside. As fine Grapes have been grown with flues as with hot water, but flues require more care, and are more liable to do mischief if not sound, or the stoker careless, or if they are allowed to get foul. If we wanted a strong heat from flues we would make a part next the furnace brick-on-bed instead of brick-on-edge. Mr. Robson had good flues formed of wide tubes of Portland cement.

CONSTRUCTION OF A VINERY (*W. J. S.*).—For sash-bar rafters 12 feet 3 inches long, you should not put for post for thirty-two postage stamps. The best bricks make the best flues, and should be well set with lime putty. We prefer they should have no plastering inside, but be roughly plastered or heavily limewashed outside. As fine Grapes have been grown with flues as with hot water, but flues require more care, and are more liable to do mischief if not sound, or the stoker careless, or if they are allowed to get foul. If we wanted a strong heat from flues we would make a part next the furnace brick-on-bed instead of brick-on-edge. Mr. Robson had good flues formed of wide tubes of Portland cement.

WATERPROOFING CALICO (*C. G.*).—Tack the calico loosely on the frame, and then paint over with the following when hot. Take one pint of linseed oil old and pale, half an ounce of acetate of lead (sugar of lead), and one ounce of white resin. Grind the acetate with a little oil, add to the rest, and the resin bruised, incorporate thoroughly in an iron pot over a slow fire, and apply with a brush when hot. Next day fasten tightly with tacks, and rub the brush round the sides where tacked. This does well when the cover can be lifted off and on like a sash of a frame, but the waterproofing is apt to crack when rolled, and in that case would be better without the resin. A flexible cloth for rolling, and tolerably waterproof, is made by a weak solution of glue, just so strong as to stick between the fingers a little when it begins to cool. Add to it as much alum as will enable the taste of alum to be discernible, then a little linseed oil, and a little soap beaten up into a lather, and when well mixed apply to the cloth, when the mixture is warm, with a brush. For mere waterproofing, when light is no object, nothing is better than a mixture of boiled oil and tar, which when dry is pliable. We have found, however, that waterproofed calico does not last so much longer, and that common calico strained tightly throws off water like an umbrella.

PLANTATION FOR SHELTER AND ORNAMENT (*W. T. Coniferæ*).—In your sheltering boundary it would be well not to plant more than from thirty to forty intended to be permanent, and fill up with a few Scotch Firs and Spruce, but chiefly with the common Laurel, which you can cut as you like afterwards. For fine specimen plants we would plant such as the following—viz., *Pinus pinaster*, *P. anstracia*, *P. cembra*, *P. strobus*, *P. excelsa*; *Abies alba*, *A. Smithiana*, *A. Douglasii*, *A. cephalonica*; *Picea pinaster*, *Picea Webbiana*, *Arucaria excelsa*, *Cryptomeria japonica*, *Taxodium sempervirens*, *Wellingtonia gigantea*, *Cedrus Libani*, *Cedrus deodara* (if something like a fourth should be *Deodars* you will not regret it), with three or four *Arancarias*, and at least a couple of *Wellingtonias*. These should be from 40 to 50 feet apart. Most of these, and especially *Arancarias* and *Deodars*, may be had well rooted and of a large size at from 10s. 6d. to 2ls. 6d. each; but if the carriage must be long we would prefer for such specimens good strong plants from 18 to 30 inches in height, and which, if well treated, will grow better every day after they are planted, whilst large expensive plants are apt to stand still for a time. However, if you wish for a few fine specimens, have them by all means, and most of our respectable nurserymen would be able to supply you with plants of almost any size, according to price.

CULTIVATING MUSHROOMS ON A GRASS PLAT (*Delta*).—Mushrooms are always uncertain in the open air. You may have them on the grass plat just as well as in a grass field; but it is rather late to insert spawn below the turf now. It would have been better if you had spawned your ground in August, inserting pieces about the size of a walnut every 18 inches or so apart, and from 1 to 2 inches below the surface. The spawn is not so much injured by cold as by wet and cold combined. We would never advise making a Mushroom bed of a lawn, as if the spawn take possession, farewell to the soft elastic bend and the smooth surface of the lawn; but a small corner might be tried. Recollect that that will be exposed to the same casualties as spawn in grass fields. We have marked places plentifully supplied with Mushrooms, and found the ground permeated with spawn, and yet for years afterwards not a Mushroom was seen in the same place. In other cases we have found Mushrooms appearing on the same pasture at the same place year after year. This has been a fine season for spawn spreading under ground.

SELECT VARIETIES OF GLADIOLUS (*C. B. Birmingham*).—*Red*: Meyerbeer, Fulton, Ensign. *Pink*: Adolphe Brongniart, Milton, Felicien David,

Lilac, &c.: Thomas Moore, Adèle Sonchet. *Various*: Ophir, Earydice, Reine Victoria, Belle Gabrielle.

Kew (X. Y. Z.).—You have imagined a prejudice which does not exist.

MUSA CAVENDISHII (*A. Constant Reader*).—The fruit you enclosed is of Musa Cavendishii, or Cavendish's Plantain. The Bread-fruit is quite a different plant, *Artocarpus incisa*. If you cut off the flowering stalk entire and hang it up in a warm dry place, the fruits upon it may ripen.

NAMES OF FRUITS (*T. W.*).—1, Laure de Glymes; 2, Belle de Noël; 4, Glon Moreau; (*R. M.*).—1, Hampden's Bergamot; 2, Beurre d'Arenberg; 3, Vicar of Winkfield; 4, St. Germain; 5, Emerald; 6, Duchesse d'Orléans. (*Centurion*).—1, Nouveau Poiteau; 2, Doyenné Defais; 3, Yellow Bellefleur; 6, Drap d'Or; 7, Braddick's Nonpareil; 8, Easter Beurre; 9, Nonpareil; 10, Hereford-hire Pearmain; 11, Red Doyenné; 12, Boston Russet; 13, Royal Russet; 14, Brown Beurre; 15, Cellini. (*J. Metcalf*).—Vicar of Winkfield. (*C. Hamilton*).—1, Stirling Castle; 2, Not known; 3, Your Winter Peach is Winter Hawthoruden; 4, Warner's King; 5, Your

Soldat Laboureur Pear is Hampden's Bergamot; 6, Your Joséphine de Malines Pear is Fondante de Malines; 7, Not known; 8, Beurre Nantais.

NAMES OF PLANTS (*G. S.*).—1, *Cratogeomys macrantha*; 2, *C. sanguinea*; 3, *C. ovalifolia*; 4, *C. punctata*; 5, *C. orientalis*; *Cicuta virosa* is found in ditches and by the sides of rivers, but we cannot give you such a description of it as to enable you to find the plant if you do not already know it; ask some botanical friend near you if he knows where it grows. (*E. L.*).—We cannot determine species from leaves. (*M. D.*).—*Aranja albus*. (*Mrs. Satterlee*).—*Canavalia trigida*. (*Polystichum*).—1, *Selaginella Krassiana*; 2, *Aspidium trifoliatum*; 3, *Echechium occidentale*; 4, 5, 1 *Polystichum aculeatum*, young fronds. (*J. S.*).—1, *Asplenium trichomanes*; 2, *Polypodium vulgare*; 3, 4, 5, *Lastrea Filix-mas*; 6, *Ruscus aculeatus*. (*J. M. C.*).—*Cassia ligulata*. (*H. T. W.*).—*Pteris sulcata*. (*An Old Subscriber*).—*Trichomanes radicans*. (*A. L. H.*).—*Datura stramonium*, a very dangerous plant. (*J. Scott*).—1, *Aster Revis*; 2, *Potentilla nepalensis*, or a hybrid from it.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the week ending October 20th.

DATE.	BAROMETER.		THERMOMETER.				Wind.	Rain in inches.	GENERAL REMARKS.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

POULTRY AT THE APPROACH OF WINTER.

THERE is something cheerful in the first approach of frost, and in the disappearance of the hot, unseasonable muggy weather. The animal world seems to share the feeling; at least, we thought our fowls did. They were brisker, they bustled more about, and when let out at daybreak, instead of listlessly wandering in front of their house, they spread all over the grass. The younger ones seemed to view the white frost with wonder, akin to that expressed by natives of hot countries, who for the first time in their lives see the landscape covered with snow.

We do not believe the relaxing weather we have had has been healthy for fowls. Without serious ailment we do not know we ever saw our fowls at all places so entirely out of condition; many sneezing, and with slight discharge from the nose, while others have shown a decided tendency to mope. Our treatment has been camphor in their water, and bread and ale for food. This has kept disease from breaking out, and the cold weather has had a most salutary effect.

The approach of anything like winter generally brings us the question—"What is the best way of providing artificial heat for my poultry?" Some talk of hot-water pipes; some of old conservatories; some would devote an attic to early chickens; and others are willing to give up the back kitchen. Nothing of the sort is required. Increased heat must be given by generous feeding. The most important points are to feed the last thing before dark, and the first thing at daybreak. Kitchen pot liquor is now a good thing to use for mixing meal, and use it warm. Let the fowls have bones to pick. Scatter fresh mould on the floors of their houses. See that no draught blows on them in their roosting place. Begin to think of your runs. In most places men are now trimming the sides of the roads, and the cuttings that are made in making the road straight can be had for a trifle. We know nothing so good for pens; it is capital stuff for fowls to bask and dust in; it is full of grass, and affords food, and does not hold wet. Two hours after a hard shower it is dry. A few shovelful of this thrown now and then into a pen keep it always fresh.

SUBDUING BROODINESS.

In your number for October 8th you say, in answer to "H. E. N.," that "there are no means of preventing a hen being broody, and it is very cruel to try. It is simply her nature, and a little patience will survive the annoyance." Now it is, of course, impossible to prevent hens of particular breeds from manifesting symptoms of broodiness; but I think it is quite possible, without cruelty, to cure them of these symptoms. I

have kept Buff Cochins for more than a year, and by the adoption of the plan mentioned below, have constantly succeeded in preventing them from persisting in their desire to sit.

The plan is simply this. I have two hen houses, situated at a considerable distance from each other, and whenever one of my hens manifests any desire to sit, she is forthwith deported to the reserve hen house, which contains no nests. Here she remains by herself for two or three days, having a full allowance of food and water provided, and then she is returned to her old quarters. This plan has never failed to be successful, and the hens subjected to the experiment have always begun to lay again within a fortnight of ceasing to lay. The philosophy of the matter seems easily explicable. The female mind is very susceptible to the influence of change of scene, and just as prudent parents send their daughters to the seaside when they are brooding over some undesirable attachment, with the view of distracting their attention from the beloved object; so I carry off hens brooding over eggs, in order to divert their attention by presenting new objects of attraction to them.

Another simple precaution is to remove the eggs from the nests twice each day.

By these means Cochins may be made nearly as profitable as egg-producers as Hamburgs or Polish.—F., Westmoreland.

THE SORROWS OF A POULTRY-FANCIER.

THIS morning, as I sat in my study preparing for the labours of the day, I heard an unusual knock at the door. In came my poultryman, looking very serious. Something evidently was wrong.

"I am sorry, sir, to say that the hen which was ill yesterday is dead."

"Dead!" said I. "Why, she seemed as if there was very little the matter with her yesterday."

"She is dead and cold this morning," replied my man. Alas! for my poultry yard. The best pullet (a Coloured Dorking), that I had, one with the best blood in England flowing in her veins, my hope for this and other years, has been suddenly taken from me, and I hardly know how I can supply her place.

Her history is as follows, and I reiterate it that others may avoid the rock upon which my hopes have been wrecked.

About ten days since she returned from a show, where, in a close competition, she had been crowned with honours, so that I hoped she would win her way on many another field. Alas! for human hopes. She was fed, I fear, too well, although with soft food only. Upon her arrival home there did not, however, seem anything the matter with her until yesterday morning, when my servant, missing her at feeding time, found her, after a search, concealed beneath a tree. She was evidently ill; her crop contained no food, and when pressed threw out watery matter, that seemed to speak of roup. She was immediately brought in-doors, placed in a hamper near the fire, and

a dose of castor oil administered. At the same time some bread soaked in warm ale, with a little cayenne in it, was given her. Those seemed to do her good; at all events, she ate the soft food placed for her in the hamper. At night she was taken to an outhouse with the floor well covered with straw, and a pill administered, made according to the directions in Mrs. F. Blair's "Henwife":—"Dried sulphate of iron, in powder, half a drachm; capsicum, in powder, one drachm; extract of liquorice, a sufficient quantity to make a mass, which is to be divided into thirty pills."

This morning she was stiff and cold. Now, did she die of roup, or of the pill?

In three years' experience of Coloured Dorkings I have lost three birds; one in my absence, another, a cock, which died in March, and so spoiled my hopes for the breeding season, and the pullet mentioned above. To the cock I administered the following pill, also recommended in the "Henwife":—"One grain of calomel, one grain of antimony, made into a pill; one to be given every evening."

I have now hurled all my pills into the fire, and shall for the future invest in nothing but Eaily's Roup and Condition Pills.—E. M. B. A.

LONG SUTTON POULTRY SHOW.

THE Show held on the 14th and 15th inst., was larger and better than in previous years, and as the weather was very favourable there was a great attendance of visitors. Not having been able to obtain a catalogue, our remarks must be much briefer than they otherwise would have been.

The poultry was ranged in two very excellent tents, and there was a superior collection of Pigeons. We regretted to find that long after all the awards were completed, some thirty pens or more of really excellent specimens were delivered at the Show, and consequently were entirely thrown out of competition. We have again and again guarded exhibitors against trusting to the last train. The *Grey Dorkings* were remarkably good as a class, and Mrs. Arkwright's triumph was gained in a very large and severe competition. In *Cochins*, the Buff and Partridge-coloured were decidedly the best; but the cup, competed for alike by all *Cochins* or *Brahmas*, fell to a pen of the Dark-feathered *Brahmas*, belonging to the Duke of Newcastle. The cockerel was indeed a magnificent bird. *Spanish* fowls have been shown at former meetings of better character than on this occasion. *Hamburghs* were good and numerous. The Black-breasted Red *Game* cup birds, belonging to the Duke of Newcastle, were excellent, and shown in the very height of good condition; and Mr. J. Fletcher's *Duckings* were also most praiseworthy. The *Game Bantams* were mostly quite overgrown, lacked condition, and some, we believe, were actually removed, they appeared so thoroughly prostrate. Some of the best Silver-spangled *Polands* we have seen for years were shown. In the class for Ornamental birds, Golden and Silver Chinese Pheasants, and a very handsome hybrid between the English Pheasant and Black Bantam hen, had hosts of admirers. The Selling Class was remarkably large; and as a sure corrective of the deception, now so common, of entering highly valued poultry at a ridiculously low figure, and instantly claiming them, all prize or commended pens were sold by auction, and the excess on the entered price was given up to the Society. This keeps out all sharp practice.

The Honorary Secretary showed a very good collection of poultry in the local class, and was most assiduous in promoting the comfort of every one.

(From a Correspondent.)

Of *Pigeons* there was a very strong show, many very good birds only receiving high commendations. First on the list were *Carriers*. The first prize for Black cocks went to Mr. Wiltshire for a cock that did not prepossess me, being sadly short of carriage and neck. In Black hens Mr. Crossley took first and second with birds of superior style. In cocks of any other colour he was first with a Dun cock with a deformed foot. In hens of any other colour Mr. Fulton deservedly won the cup for the best Carrier of any colour with a magnificent Dun hen, late the property of Mr. Hedley, that has taken a prize wherever shown. I would throw out a hint here, that Judges are too prone to give prizes to Carriers that are sadly too coarse, in preference to such birds as those shown here by Mr. Walker in cocks, and Messrs. Crossley and Fulton in hens, which possessed plenty of style and carriage combined with head and beak. In *Porter* cocks, Red or Blue, Mr. Fulton was first, but not with, in my opinion, his best birds. He also took first in Red or Blue hens, and the same in both classes for any other colour.

In *Almonds* Mr. Wiltshire took the cup with a pair that had been overtriumphed in the beak, but nevertheless good birds. In *Tumbler* of any other variety Mr. Fulton was first with a good pair of Agates, and Mr. Crossley second with a good pair of Blacks. For *Jacobins* Mr. Horner was first, and Mr. Fulton second, with Reds. *Fantails* were fair. In *Orls* Mr. Fielding was first and second. *Turkies* were a fair, and *Barbs* a good class, Mr. Wiltshire taking the cup, and Mr. Crossley being second. *Dragon* were a strong class, Mr. Horner taking

the first prize. For "any other variety" the first prize went to a very good pair of Yellow Magpies and the second to *Hyalanthus*.

Of *Rabbits* there were many good specimens, and the prizes were justly awarded. The following is the prize list:—

DORKINGS (Coloured).—Cup, Mrs. Arkwright, Etwell Hall, Derby. Second, Duke of Newcastle, Clumber. Highly Commended, D. Gellatly, Meigle, N.B.; Mrs. Arkwright; B. Dawson, Leybourne; Dr. Campbell, Brentwood; Hon. H. Fitzwilliam, Wentworth Woodhouse; J. Clift, Dorking; H. Pickles, jun., Early. Commended, J. Vorley, Holbeck; H. Linwood, Barking, Needham Market; G. Clarke, Long Sutton.

DORKINGS (Any other variety).—First, Mrs. Arkwright (Silver-Grey); Second, Dr. Campbell (White). Highly Commended, O. E. Cresswell, Hanworth (Silver).

COCHIN-CHINAS (Buff).—First, W. A. Burnell, Southwell. Second, C. Sidgwick, Ryddlesden Hall, Kighley. Highly Commended, L. H. Ricketts, Barnwell; H. Lingwood.

COCHIN-CHINAS (Any other colour).—First, J. K. Fowler, Aylesbury (Partridge). Second, W. Warren, Gedney Dyke. Highly Commended, T. M. Berry, Godney (Partridge). Commended, Mrs. J. Clarke, Long Sutton (White); Rev. R. Hollis, Whaplode Grove (White).

BRAMHAS (Dark).—Cup, Duke of Newcastle. Second, E. Alder, Derby. Highly Commended, E. Alder; H. Saville, Rufford Abbey, near Olderton.

BRAMHAS (Light).—First, H. Dowsett, Pleshey, Chelmsford. Second, G. Hustler, Stillingfleet, York. Highly Commended, J. Parcs, Postford, Gaidford.

SPANISH.—First, H. Snashall, Gedney. Second, A. Cole, Long Sutton. **HAMABRONS** (Golden and Silver-spangled).—Cup, J. Laming, Cowburn, Spalding (Golden). Second, H. Pickles, jun. Highly Commended, J. Walker, Haye Park, Knaresborough; Ashton & Booth, Broadbottom, Manchester (Silver); S. & R. Ashton, Mottram, Cheshire (Golden). Commended, W. McMillan, Glossop.

HAMABRONS (Golden and Silver-pencilled).—First, J. R. Jessop, Hull. Second, A. Cole (Golden). Highly Commended, J. Webster, Whitby (Golden). Commended, J. Walker.

GAME (Black-breasted and other Reds).—Cup, Duke of Newcastle. Second, J. Fletcher, Stonecough, Manchester. Highly Commended, J. Fletcher; F. B. Hall, Cambridge; W. Goose, Long Sutton (Brown-breasted); G. R. Smith, Scarborough.

GAME (Duckwing and other Greys and Blues).—First, J. Fletcher (Duckwing). Second, T. Robertshall, jun., Illingworth, near Halifax (Duckwing).

GAME (Any other variety).—First, E. Crawford, Long Sutton (Black). Second, W. Dale, Weston-super-Mare (Pile).

FRENCH FOWLS (Any variety).—Cup, Col. Stuart, Wortley, Grove End Road, London. Second, Hon. C. Fitzwilliam (La Fleche). Highly Commended, J. O. Hobson, Long Sutton (Creve-Cœur); J. K. Fowler (Creve-Cœur and La Fleche). Commended, T. Fox, St. Catherine's, Lincoln; Hon. H. Fitzwilliam (La Fleche).

GAME BANTAMS (Black-breasted Reds).—Cup, Rev. C. H. Crosse, Cambridge. Second, J. Crosland, jun., Wakefield. Highly Commended, W. F. Entwistle; J. W. Morris, Rochdale; W. Adams, St. Clements, Ipswich. Commended, W. F. Entwistle; J. Crosland, jun.

GAME BANTAMS (Any other variety).—First, T. Whittaker, Melton Mowbray (Pile). Second and Highly Commended, J. Crosland, jun. (Duckwing). Commended, W. F. Entwistle (Duckwing); J. M. Morris (Duckwing); Mason & Charlesworth, Chesterfield.

BANTAMS (Any variety except Game).—Cup, G. Clarke (Black). Second, H. Draycott, Hamerstone, near Leicester. Highly Commended, Mrs. Woodcock, Leicester (White Japanese); H. Pickles, jun. (Black); E. Cambridge, Stowmore near Bristol (Black); J. W. Morris (Black); H. Draycott. Commended, T. C. Harrison, Hull; R. B. Riley, Ovenden, near Halifax; W. H. Tomlinson, Newark (Black).

ANY OTHER VARIETY.—First, J. K. Fowler (White Frizzled). Second, J. Laming. Highly Commended, G. W. Boothby, Louth (Silver Polish); S. S. Mossop, Long Sutton (Buff Polish). *Chickens*.—Cup, H. Pickles (Polish). Second, C. Sidgwick (Black *Hamburghs*). Highly Commended and Commended, H. Saville.

ORNAMENTAL (Any breed).—First, J. Mayes, Long Sutton (Golden-Pheasants). Second, H. Bates, Spalding (Silver Pheasants). Highly Commended, H. Perry, Long Sutton (Tipping Bullfinch); G. Clarke (a cross between a Black Bantam and a Pheasant); G. Lee, Davesmere, Long Sutton (Silver Pheasant). Commended, G. Clarke (Common Pheasants).

TURKEYS.—First, Mrs. Harris, Sutton, St. James. Second, S. H. Stott, Quarry Hill, Rochdale. Highly Commended, W. Sanday, Holme Pierrepont, Nottingham; W. Wright, Long Sutton; Mrs. Harris.

DUCK (Aylesbury).—First, J. K. Fowler. Second, S. H. Stott. Highly Commended, Mrs. Goodliif, Conington Lane, Sutton; J. K. Fowler. Commended, G. Hustler.

DUCKS (Ronen).—First, J. Stott, Quarry Hill, Rochdale. Second, J. White, Whitley Netherton, near Wakefield. Commended, Mrs. J. A. Clarke.

DUCKS (Any other variety).—First, T. C. Harrison. Second, H. Saville (Carolina). Highly Commended, T. C. Harrison; Mrs. Goodliif (White Call). Commended, S. Barn, Whitley (Black East Indian).

GEESSE (Any variety).—First, J. K. Fowler (Foulhouse). Second, G. Hustler (Tonhouse). Highly Commended, S. H. Stott; Mrs. Buffham, Lofus, Saltburn by the Sea. Commended, Mrs. Goodliif.

SELLING CLASS.—First, Dr. Campbell (White Dorkings). Second, W. A. Burnell (Buff Cochins). Highly Commended, J. Laming (Silver-spangled); P. Hutchinson, Spalding (Buff Cochins); C. W. Gibbs, Long Sutton Marsh (Golden-pencilled); Mrs. J. A. Clarke, Long Sutton (Ronen Ducks); S. S. Mossop (Partridge Cochins); J. Webster (Golden-pencilled). Commended, H. Snashall (Coloured Dorkings); C. W. Gibbs (Aylesbury Ducks); Mrs. J. Clarke, Long Sutton (Light Brahmas); G. T. Peel (Game); A. Cole (Spanish); Rev. F. Tearle, Newmarket (Silver-spangled); S. S. Mossop (Buff Cochins).

LOCAL.—First, H. Snashall (Black Spanish). Second and Third, A. Cole (Golden-pencilled and Black Spanish).

BANTAMS (Any other variety).—First and Cup for greatest number of points, G. Clarke (Black Bantams). Second, S. S. Mossop (Polish). Third, J. O. Hobson (Creve-Cœur).

PIGEONS.

CARRIERS (Black).—Cock.—First, F. T. Wiltshire, West Craydon. Second, R. H. Artindale, West Derby, Liverpool. Highly Commended, F. T. Wiltshire; E. Walker, Leicester. *Hens*.—First and Second, E.

Crossley, Elland, York. Highly Commended, R. H. Artindale; E. Horner, Harewood, Leeds; R. Fulton, Deptford, Commended, R. Fulton. **CARRIERS** (Any other colour).—Cock.—First, F. Crossley. Second, R. Fulton (Dun). Highly Commended, L. Wren, Lowestoft; E. Walker (Dun); E. Horner; R. Fulton (Dun). **Hens**.—Cup, R. Fulton (Dun). Second, F. Crossley. Highly Commended, E. Horner; R. Fulton (Dun). **POTTERS** (Red or Blue).—Cock.—First and Commended, R. Fulton (Blue). Second, A. H. Stewart, Birmingham. Highly Commended, F. Crossley. **Hens**.—First, R. Fulton (Red). Second, F. Crossley. Highly Commended, A. H. Stewart; E. Horner.

POTTERS (Any other colour).—Cock.—First and Second, R. Fulton (Black and White). Highly Commended, A. H. Stewart. Commended, A. Heath (White). **Hens**.—First, R. Fulton (Black). Second, A. H. Stewart. **TUMBLERS** (Almond).—Cup and Second, F. T. Wiltshire. Highly Commended, F. Crossley; R. Fulton.

TUMBLERS (Any other colour).—First, R. Fulton (Agate Mottles). Second, F. Crossley. Highly Commended, J. Thomson, Bingley (Yellow Mottled and Blue Beard); E. Horner; R. Fulton (Agate Mottles). **JACOBS**.—First, E. Horner. Second, R. Fulton.

FANTAILS.—First, H. Draycott, Humberstone, near Leicester. Second, W. H. Tomlinson, Newark. Commended, H. Yardley, Market Hall, Birmingham; W. R. Park, Abbot's Meadow, Melrose; E. Horner.

OWLS.—First and Second, J. Fielding, jun., Rochdale. Highly Commended, F. Crossley.

TURBITS.—First, W. R. Park. Second, H. Yardley. Commended, J. Thompson.

BARS.—Cup and Highly Commended, F. T. Wiltshire. Second, F. Crossley. Commended, E. Horner.

DRAGONS.—First, E. Horner. Second, G. Louth, East Acton. Highly Commended, R. H. Artindale; H. Yardley; E. Horner. Commended, Mrs. Arkwright, Etwell Hall, Derby; F. Crossley.

ANY OTHER VARIETY.—First, E. Horner. Second, J. Barnes (Hyacinths). Highly Commended, Mrs. Woodcock, Leicester (White Trumpeters); H. Yardley; H. Draycott (Toys); E. Horner. Commended, J. Thompson.

SELLING CLASS.—First, W. Massey, (Fantails). Second, F. Key, Beverley. Commended, H. Snaishall, Gedney (Blue Turbits); H. Yardley; F. Clarke, Long Sutton (German Ice); J. Thompson; T. C. & E. Newbitt, Epworth.

RABBITS.—Any Pure Breed.—First, M. Millington, York (Black and White Doe). Second, A. H. Easton, Hull (Yellow and White Lop-eared Buck). Highly Commended, J. T. & E. S. Codling, Whaplope (Lop-eared Buck); M. Millington (Fawn Doe). **HEAVIEST**.—First, P. Booth, Spalding. Second, W. Jeffrey, Long Sutton. Highly Commended, T. Taylor, Sheffield.

The Judges for Poultry were Messrs. Edward Hewitt, of Birmingham, and Richard Teehay, of Preston; and Mr. W. B. Tegetmeier, of London, awarded the Pigeon prizes.

WOLVERHAMPTON POULTRY SHOW.

The prize schedule was very liberal, and was well responded to by exhibitors generally. The Agricultural Hall at Wolverhampton is well adapted for a show of this description, and the arrangements connected with the poultry and Pigeons were complete. There is one arrangement, however, that might be altered to meet the views of owners of exhibition poultry. Exhibitors do not seem to approve of the birds being confined from Saturday afternoon until Monday morning before being judged. Perhaps the Committee, who are most desirous to meet the wishes of every one, will at least give this due consideration when arranging their next prize schedule. If, too, a little more time could be given to the judging it would prove an advantage.

The *Dorkings* were far better than was anticipated; whilst, strange to say, the *Spanish* class, which last year was the pride of the Show, was this year comparatively meagre. It would seem as if the great superiority of last year's *Spanish* class prevented many from making entries this year, considering their chances of success as hopeless. *Cochins* were, as usual here, very good; and the *Hamburghs* were beyond a doubt far superior to those hitherto shown in this district. The *Black Hamburghs* were peculiarly good, and several very good pens of dark-feathered *Brabans* were well shown. *Game* proved very fine and numerous. The class for *French* fowls was a complete success. The *Bantams* were not so good as these classes were last year. More than forty pens competed in the selling class, and numbers of these pens were claimed. The classes for pairs of pullets, the *Geese*, the *Turkeys*, and the *Ducks* were admirable.

It is long since so excellent a collection of *Pigeons* was shown at Wolverhampton, and the condition of most of the birds was faultless. The weather proved most satisfactory, and the number of visitors showed that poultry-culture is becoming even more popular than ever.

DORKINGS (Any colour).—First and Third, Mrs. Arkwright, Etwell Hall. Second, J. L. Lowndes, Hartwell. Highly Commended, Countess of Dartmouth, Patsball Hall (Grey); Hon. H. W. Fitzwilliam, Rotham. Commended, Hon. H. W. Fitzwilliam; Mrs. Bailey, Shooter's Hill; J. L. Lowndes, Hartwell (Silver-Grey).

SPANISH.—First, J. Walker, Wolverhampton. Second, J. Smith, Keighley. Third, M. Eggington, Wolverhampton. Commended, T. Bamfield, Clifton.

COCHIN-CHINA (White).—First, Cochins Cup, and Third, R. Chase, Ball's Heath. Second, Mrs. A. Williamson, Leicester. Highly Commended, G. Lamb, Compton; Mrs. A. Williamson.

COCHIN-CHINA (Partridge).—First, R. Story, Derby. Second, E. Tulman, Whitechurch. Third, Hon. Mrs. Sugden, Wells. Highly Commended, J. K. Fowler, Aylesbury. Commended, S. Wilson, Oswestry. E. Story.

COCHIN-CHINA (Buff and Cinnamon).—First, Hon. Mrs. Sugden. Second, J. Lee. Third, A. Darby. Highly Commended, E. Brindley; C. Sidgwick, Keighley; W. A. Burwell, Southwell; J. H. Dawes, Moseley Hall; H. Mapplebeck, Woodfield. Commended, C. Banbery, Penn Fields;

J. N. Beasley, Brampton; T. Groves, Shrewsbury; A. De Metz, Compton; G. Lamb; Rev. S. C. Hamerton, Warwick; J. Cattell, Birmingham; H. Mapplebeck.

HAMBURGHS (Golden-spangled).—First, J. Walker, Haya Park. Second, I. Davies, Harborne. Third, T. May, Wolverhampton. Highly Commended, H. Beldon, Goitstock; E. Brierley, Heywood. Commended, T. Bolton, Hanford; J. Chadderton, Hollinwood; T. C. & E. Newbitt, Epworth.

HAMBURGHS (Silver-spangled).—First and *Hamburgh Cup*, also extra Two Guineas for the best pen of *Hamburghs*, Duke of Sutherland, Trentham Hall. Second, J. Walker. Third, H. Beldon. Highly Commended, Mrs. Flynn, Kidsgrove; Ashton & Booth, Mottram; J. Robinson, Garstang.

HAMBURGHS (Gold-pencilled).—First, W. R. Park, Melrose. Second and Third, H. Beldon. Commended, F. D. Mort, Stafford; J. Walker; W. Parr, Patricroft.

HAMBURGHS (Silver-pencilled).—First, Duke of Sutherland. Second, T. Hanso, Keighley. Third, H. Beldon. Highly Commended, H. Beldon; W. & J. Bairstow, Fearcliff. Commended, J. Robinson.

POLISH.—Prize, H. Beldon. Highly Commended, R. P. Williams, Dublin.

BRAHMAS.—First, R. W. Beachey, Newton Abbot. Second, L. Pointon, Biddulph. Third, C. Layland, Warrington.

GAME (Black or Brown-breasted).—First and Two Guineas Victualers' prize, also the President's Cup of Five Guineas, G. Bentley, Stone (Black Red). Second, J. Fletcher, Stoneclough. Third, J. Platt, Winsford. Commended, W. H. Cadwallader, Compton; W. Dunning, Newport; G. Lunt, Adderley (Brown Red); E. Brough, Leek (Brown Red); J. Platt, Winsford; J. Fletcher; G. Swift, Fulford.

GAME (Any other variety).—First, J. Fletcher (Duckwing). Second, T. Dyson, Halifax (Duckwings). Third, W. Dunning, Newport (Duckwing). Commended, R. B. Riley, Ovenden (Duckwing); R. Swift, Southwell.

FRENCH FOWLS.—First, Hon. H. W. Fitzwilliam (Crève-Cœur). Second, W. A. Burnell (La Flèche). Highly Commended, W. Butler, Wolverhampton (Houlan); J. K. Fowler, Aylesbury (Crève-Cœur and La Flèche). Commended, W. R. Park (Crève-Cœur); R. B. Wood, Uttoxeter (Crève-Cœur); Mrs. M. Seamons, Hartwell (Crève-Cœur).

BANTAMS (Black Red).—First, J. Crosland, jun., Wakefield. Second, W. Griffiths, Nantwich. Third, J. J. Cousins, Allerton. Highly Commended, J. Adkins, jun., Walsall; J. J. Cousins.

BANTAMS (Any other variety).—First, W. H. Tomlinson, Newark (Black). Second, Mrs. Woodcock (White Japanese). Third, S. & R. Ashton, Mottram (Black). Commended, H. Draycott, Humberstone.

ANY OTHER VARIETY NOT PREVIOUSLY MENTIONED.—First and Second, Mason & Walker, Denton (Black *Hamburghs*). Third, Rev. A. G. Brooke, Ruyton-XL-Towns (Malays). Highly Commended, Rev. W. P. Story, Daventry (Silky Niggers); J. K. Fowler (Silky Japanese); W. Parr, Patricroft (Black *Hamburghs*). Commended, W. A. Burnell, Southwell (Andalusian); E. Geary, Brierley Hill (Pea Fowl).

SELLING CLASS.—First, J. Walker (Black Spanish). Second, C. Banbery (Buff Cochins). Highly Commended, Rev. P. W. Story (White-feathered-legged); H. Yardley, Birmingham; J. Dewhurst, Clitheroe (Dark *Brabans*); H. Bagshaw, Uttoxeter (Golden-spangled *Hamburghs*); Rev. W. Serjeantson, Acton Burnell (Black *Hamburghs*); A. De Metz (Black Spanish); G. Lamb (Partridge Cochins); G. Lunt, Adderley (Game Piles); J. Robinson; T. Blakeman (Gold-spangled *Hamburghs*). Commended, Rev. P. W. Story (Japanese *Bantams*); R. P. Williams (Golden Polish); L. Pointon (Dark *Brahma*); J. Platt, Winsford (Brown Red); T. Peake, Compton (Duckwing *Bantams*); T. Grove (Cochin-China); Bowman & Fearon; J. Walker (Hamburgh); Mrs. A. Williamson (White Cochins); Rev. S. C. Hamerton, Warwick; W. Nottage, Northampton (Spanish).

SINGLE FELLETS.

DORKINGS.—First, Countess of Dartmouth. Second, Mrs. Arkwright. Highly Commended, Hon. H. W. Fitzwilliam; E. Shaw. Commended, Rev. E. Bartrum, Great Berkhamstead.

COCHIN-CHINA.—First, J. Robinson. Second, G. A. Crewe, Etwell. Highly Commended, Bowman & Fearon; Capt. D. Lane; G. Lamb; J. Cattell, Birmingham; H. Vaughan; Mrs. Woodcock. Commended, Hon. Mrs. Sugden; W. A. Burnell; J. H. Dawes; G. Lamb; J. Stephens, Walsall.

HAMBURGHS.—First, J. M. Kilvert, Ludlow. Second, T. Blakeman. Highly Commended, Rev. W. Serjeantson, Acton Burnell; J. Walker. Commended, G. F. Whitehouse, King's Heath; E. Waterhouse; E. Brierley; J. Robinson.

GAME.—First, J. Mason, Worcester. Second, H. C. & W. J. Mason, Leeds. Highly Commended, W. H. Mitchell, Moseley; G. Bentley, Stone; E. Brough, Leek. Commended, Capt. D. Lane; W. Bradley, Worcester; G. Clements, Birmingham; G. Swift, Fulford.

PRESIDENT'S PRIZES.—First, T. May, Bloomsbury, Wolverhampton. Second, J. Walker, Wolverhampton. Third, W. Smallwood, Wolverhampton.

TURKEYS.—First, S. H. Stott, Rochdale. Second, F. E. Richardson. Highly Commended, F. E. Richardson, Uttoxeter. Commended, J. K. Fowler, Aylesbury.

GEES.—First, Mrs. M. Seamons, Hartwell. Second, J. K. Fowler. Highly Commended, J. Timmins, Prestwood; S. H. Stott.

DUCKS (Aylesbury).—First and Commended, Mrs. M. Seamons. Second, J. K. Fowler. Highly Commended, E. Leech, Rochdale. Commended, R. P. Williams, Dublin.

DUCKS (Rouen).—First, G. Bagnall, Cheadle. Second, J. White, Wakefield. Commended, J. Robinson.

DUCKS (Any other variety).—First, R. P. Williams (Ruddy Shelducks). Second, Rev. W. Serjeantson, Acton Burnell (Black East Indian). Highly Commended, Sir J. Morris, Kt., Elmsdale (Summer or Carolina); R. P. Williams, Dublin (Brahmas).

PIGEONS.

TUMBLERS.—First, J. Hawley. Second, J. Fielding, jun. Highly Commended, W. Choyce, Silson. Commended, H. Yardley, Birmingham.

CARRIERS.—First, J. C. Ord, London. Second, H. Yardley. Highly Commended, E. Horner, Leeds; H. Yardley; J. C. Ord. Commended, J. Hawley.

POTTERS.—First, J. E. Beward, Great Barr. Second, J. Hawley. Highly Commended, H. Yardley. Commended, J. E. Beward.

FANTAILS.—First, J. E. Beward. Second, H. Yardley. Highly Commended, F. H. Paget, Leicester; J. Hawley; H. Draycott, Humberstone; W. Choyce; H. Yardley; J. E. Beward. Commended, W. Choyce.

ANTWERPS.—First and Second, J. Cox, Wolverhampton. Very Highly Commended, J. W. Wilkinson, Bradford. Highly Commended, — Hunter, Wolverhampton; J. Hawley; H. Acutt, Wolverhampton; W. Butler, Walsall; T. A. Dean, Hereford; H. Yardley; J. Thompson, Bingley; J. Crossland, jun.; J. W. Wilkinson; W. Hughes, Wolverhampton. Commended, H. Yardley; W. H. Mitchell, Moseley; H. Allsopp, Birmingham; B. Benton, Wolverhampton.

DUNOONS.—First, H. Allsopp. Second, E. Butterworth, Nantwich. Highly Commended, E. Butterworth; D. Bromley, Over Hulton; H. Yardley; H. Vaughan, Wolverhampton. Commended, H. Yardley; J. Thompson; A. Roote, Crewe.

ANY OTHER VARIETY.—First, H. Draycott (Frillbacks). Second, H. Yardley. Third, J. Fielding, jun., Rochdale (White Owls). Highly Commended, H. Yardley; H. Draycott (Toys); T. Bywater, Wolverhampton; T. H. Frean, Liverpool (Black Barbs); J. E. Breward (Black Swallows); W. Choyce (Magpies); E. Horner, Leeds. Commended, W. Price, Handsworth (Blue, and Yellow Owls); F. H. Paget; T. Booth, Church Lawton (Blue Chequered Owls); J. Thompson.

The Judge was E. Hewitt, Esq., of Sparkbrook, Birmingham.

NATIONAL PERISTERONIC SOCIETY.

UNION is strength, if we may judge by the last Exhibition of this Society at the Freemasons' Tavern, Great Queen Street, London. As our readers are, no doubt, aware, this Society consists of the Philo-peristeron and the National Columbarian Societies amalgamated, and we are happy to learn that the Society will hold a show at the Crystal Palace in January next. We would be glad to see it extended to two days instead of only one day, and such an extension of time we think the promoters would do well to consider.

Carriers were shown in large numbers. Mr. Hedley having a very good pair of Duns, Mr. Else some good Blacks, Mr. Ord a very good Black hen, and Messrs. Feltham and Maynard some very good specimens. Mottles and Beards came from Mr. Esden, and amongst them was a very good Black Beard. Jacobins and Fantails were shown by Mr. Maynard, and Barbs by Messrs. Maynard and Hedley.

BLACK-LEGGED FOWLS.

I HOPE you will aid me in an attempt to break through a prejudice which tends to keep "poultry meat" at a higher price than necessary. Few persons have any idea of the extent to which we are tyrannised over by our cooks and the poultrymen. The former say, "Oh, white-legged fowls look so much better on the table than those with dark legs;" and the latter, of course, meet the views of their patrons—the cooks, by offering for sale only those with white legs, to the exclusion of the far more numerous class with dark legs. Dark-legged poultry is so tabooed, that it is not to be found in the shop of any English poulterer. Now, I must beg attention to a little common sense in this matter. In France the favourite fowls are of the following breeds:—La Friche and Crève-Cœur, the legs of which are as dark as can be, the legs of the Houdan are not quite so dark; these three classes are now conspicuous in our poultry shows, and might be imported advantageously, but the poultryman knows the prejudiced English cook looks to what she considers appearance, and will not buy them. The Spanish fowl is one of the most common in all parts, thriving equally in town as in country; it is a most excellent table fowl, but it, too, has dark legs.

New English cookery books, written more for sale than for information, pander to the well-known and absurd prejudice; but all the old books, under the heading "To Choose Poultry," say, "Dark-legged fowls are the most juicy and best flavoured." Evidently the French are of that opinion. My family, as well as myself, prefer dark-legged poultry, as sweeter and more nourishing; but my object is not to disparage one description of fowl at the expense of the other, but rather to remove disabilities which prejudice has thrown over the appearance in the kitchen of one highly-deserving class—viz., the dark-legged.

In rearing I have found the dark-legged harder than the white in the proportion of four to three. Consult a knowing person in the country on what fowls to keep, and the first question asked will be, "For your own consumption or market?" And then the secret comes out—"White legs for market, their appearance fetches top price; but give me dark legs for a nice fowl at home."

We live in thralldom under our cooks' ideas of the elegant; get rid of this, and home and foreign poultry will be more plentiful in our markets, and prices lower. I venture to say, from practical experience, the pair of fowls now purchased in London for 8s. has not cost more than 5s., and that out of the 3s. difference as much as 1s. 6d. is for the appearance of the legs.

Claiming for dark legs the honours of *la cuisine*, so richly their due, I am, the Gallic cock—*LA Friche* (Times).

A MICROSCOPICAL INVESTIGATION INTO THE NATURE AND ORIGIN OF FOUL BROOD.

I HAVE much pleasure in laying before the apian readers of "our Journal" the following translation of a very interesting paper which appeared in the last number of the German Bee Journal, and shall be glad if "R. S." and other observers who are interested in the subject, will favour us with their opinions upon the theory which is therein promulgated. Its author, Dr. Preuss, of Dirschau, is a physician of great eminence, and wide-spread reputation, "Sanitätsrath," or Sanitary Councillor, being an honorary title conferred by the Prussian government only upon distinguished members of the medical profession; and whatever we may think of the fungoid theory which he advances, it must be conceded that he is tolerably correct in his treatment of the disease, and that we have to thank him for a painstaking and laborious effort to dispel the mystery which has so long enshrouded its origin, as well as the mode in which, under certain circumstances, it becomes so rapidly developed and propagated.—A DEVONSHIRE BEE-KEEPER.

THE EXISTENCE OF VIRULENT FOUL BROOD DEPENDENT UPON A MICROSCOPIC FUNGUS, *CRYPTOCOCCUS ALVEARIS*.

IT CAN BE PREVENTED AND CURED.

Although I have seen bee-keeping carried on from my earliest childhood, and have myself pursued it during seventeen years, in Dzierzon and straw hives, with German, Italian, and Egyptian bees, and have taken occasion to examine numerous apiaries in the valley of the Vistula from Dantzig to Plock, in Poland, it was not until 1866 that I anywhere met with foul brood.

Bee-keeping in the Vistula valley is generally carried on in straw hives, and is very prosperous owing to the rich pasturage furnished first by the extensive fields of rape seed, then by the white clover, and in the autumn by the wild mustard. In the neighbourhood of Dirschau and Dantzig there are, indeed, numerous apiaries of Dzierzon hives, and at Gutland, one mile from Dirschau, my friend Wannow keeps bees entirely in hives of this description.

Two years ago, whilst he still possessed a magnificent apiary of seventy hives, mostly in bee-houses, he called my attention to the fact that foul brood had made its appearance among them. We did not at that time lay any particular stress upon it, and this is an error against which we can scarcely warn bee-keepers sufficiently. When I visited him again shortly afterwards, I was astonished at finding this beautiful apiary dwindled to one-half its former number, and still continuing diseased. I immediately purposed to devote myself to the investigation of this horrible malady, especially to the microscopical examination of the foul-broody substance, and I here communicate the result.

The statement of Von Molitor-Nüßfeld, of Mannheim, that a saw-fly is the cause of this disease, we have not found confirmed in a single instance, the minute perforations which sometimes exist in the cell-covers being made by the bees. Never have we, either with magnifier or microscope, found in the cells the eggs or maggots of saw-flies; never have we found in the hive even the saw-flies themselves. Neither can we endorse the theory of Dr. Assmuss, that the disease is produced by the larva of *Phora incrassata*.

Foul brood, as is well known, has a viscous, gelatinous, and yeast-like appearance, and an unpleasant odour. Foul-broody cells may be recognised by their sunken covers.

In order to be able to set about the microscopical investigation of this disease, it is necessary to possess a microscope which has a magnifying power of at least 200 to 400 diameters. Mine is an excellent instrument by Brunner, of Paris, and my observations have been made with a magnifying power of 600 diameters. It possesses also a micrometer which will measure to the ten-thousandth part of a millimetre, or the twenty-thousandth part of a line.

It is also essential that we operate very neatly and with as little contamination as possible. The investigation is best conducted when the blue sky sheds its light on the field of the instrument—not the direct rays of the sun, or a reflected light from a building or such like. A retired room that is unshaken by passing vehicles, and a firmly-fixed table are also required. The instrument itself should be levelled in a horizontal plane.

A great many observers as well as beginners commit the mistake of placing too great a body of matter on the glass slide,

in which case nothing can be seen but a chaotic mass. It was against this error that my respected and highly-honoured preceptor, Ehrenberg, of Berlin, warned his scholars the most.

When the microscope is properly adjusted, we dip the end of a clean and very slight rod, either of glass or wood, into a foul-broody cell, and by this means deposit a particle of the matter about the size of a grain of sand (a portion even of the size of a millet grain would be too large), upon a very perfect glass slide scrupulously cleaned by means of wash-leather. We then dip another fine rod in freshly-distilled water, or in fresh rain water caught in a clean porcelain vessel (if the water be not quite fresh it becomes impregnated with organic matter, whilst spring water would deposit crystals and thus vitiate the operation), and by means of this perfectly clean rod dipped in absolutely pure water, we deposit a drop of the size of a millet grain, and no more, on the particle of foul brood of the size of a grain of sand, which by this means diffuses itself a little in the water. The whole being covered with a thin glass about the substance of a poppy-leaf, we have a preparation by means of which long and careful studies can be made. If we place it under the microscope we see a thousand dust-like bodies which are known to the microscopist as fungi, and which belong to the species *Cryptococcus* (Kützing). These are best seen at the edges of the mass where they are scattered singly; but if the observer has neglected the precautions before indicated he will not be able to detect the fungi singly, nor will he indeed see anything of which he can undertake the examination. If we find different-sized bodies, the larger are fatty particles, the remains of the bee chrysalis, and those which are smallest of all and dust-like are the fungi.

The foul-brood fungus, which I have named *Cryptococcus alvearis*, belongs to the smallest of fungoid forms. It is round and dust-shaped, and has a diameter of 1-500th millimetre, or 1-1095th line. Consequently 1095 can lie side by side within a Rhenish line, but within a square line 1095×1095 —that is, 1,199,825, or in round numbers, 1,200,000. The cubic line according to this would contain 1,410,000,000,000 fungi; and a cubic inch of foul brood, which consists of 1728 lines, would contain 2,488,320,000,000,000. If we reckon further that a cubic inch of comb contains 50 cells, the contents of each cell would be 49,766,400,000,000—in round numbers, fifty billions, or, deducting one-fifth for wax, forty billions of fungi.

It is only this enormous capability of increase which renders foul brood so dangerous, as is, indeed, the case with the cholera, typhus, and small-pox fungi, &c.

Foul brood is no more a poison than is any strong rank-growing weed: it merely supplants that which otherwise would live and thrive. It is closely allied to the fermentive fungus *Cryptococcus fermentum*, which by its rapid increase in fluids capable of fermentation, transmutes them, and, after it has consumed all the elements which are capable of serving for its reproduction, precipitates itself in the form of lees. Beer and wine lees are in like manner a conglomeration of microscopic fungi.

The actual nature of foul brood being clearly defined, everything else follows of itself. The extraordinary facility with which it may be communicated must be indubitable; so long as it lies jelly-like and covered in the cells it is perhaps the least dangerous; but when it rests dry, and like a black crust on the edges of the cells, or falling down within the hive is scattered abroad like dust, then billions of sporules are sown broadcast. They adhere to the feet of the bees, enter the cells filled with young brood, become transferred to other hives through resting on flowers, &c., and thus the disease may be spread in a thousandfold manner.

It is well known that it is not the larva, but the sealed chrysalis that first dies of foul brood and is then consumed by it. The fungus, however, first attaches itself to the larva, but in trifling quantity, for some thousand sporules cannot injure it; so pass the six days of its larval life. It has within itself the germ of death, but yet it lives. When in the nymphoid state it is killed by the fungus multiplying prodigiously in geometrical progression, which also continues to increase after the death and at the expense of the chrysalis, which it ultimately changes entirely into itself.

I should define the distinction made by Dzierzon between non-contagious and virulent foul brood as consisting in this—that non-contagious foul brood means the death of the larva from other causes, and virulent foul brood the death of the larva from foul brood fungus.

With respect to the origin of foul brood independently of infection, we have seen above that the foul brood and fermentive

fungi are of the same species, and it is also known that fungi, especially the microscopic kinds, change and transform one into the other, according to the different substances upon which they alight.

It is in this way highly probable that the fermentive fungus, *Cryptococcus fermentum*, may, when it comes in contact with, or when as food it enters the body of, the bee larva, change itself, under peculiar conditions of temperature and moisture, into *Cryptococcus alvearis*, or foul brood fungus.

All practical bee-keepers complain of feeding with fermenting honey as the principal cause of foul brood; and fermenting honey arises in the first instance if, when the honey is taken possession of, the sealed or open combs containing brood are not carefully separated from the honeycombs, in which case the honey becomes mingled with alumen, and is useless for feeding. We cannot, therefore, be too careful in using honey for bee food.

Mr. Wannon, of Gütland, a very assiduous and intelligent apiarian, always asserted, long before I had begun my microscopical investigations, his conviction that foul brood had arisen with him through giving his bees meal as food, or that it had at any rate been greatly increased by it. Although no other similar observation has reached me, I yet esteem this experience of a thoroughly practical man as well worth notice. Meal is an exceedingly favourable soil for the propagation of the fermentive fungus, as is proved by the abundant fermentation which follows the addition of yeast to dough. It may, therefore, be advisable, at least in hives which are already diseased, to eschew the use of meal as food.

As the fermentive fungus is very much diffused throughout nature, and as countless multitudes of its sporules float in the atmosphere, so they, without being greatly assisted in their increase by fermenting liquors, when they have the opportunity of establishing themselves on a soil which agrees with them, contrive to carry out their propensity for multiplication. A particularly favourable soil is found in dead and mouldering larvae or chrysalids; and for this reason, if brood which has died from cold or other causes be permitted to remain in the hive, it may occasion virulent foul brood without feeding with deleterious honey or such like.

The removal of a hive, by which too many bees are lost, and those remaining are unable to foster the brood, may promote foul brood. The multiplication of stocks by artificial means, by which, when the proportion of bees to the brood is too small, the latter may readily be chilled to death, is more favourable to the outbreak of foul brood than natural swarming. I have on a former occasion advised for the prevention of chill, the warming of artificial swarms by means of corked bottles filled with hot water—a practice which I have found very beneficial. We are, therefore, very careful that dead brood, especially such as is sealed over, should be removed as soon as possible from the hive and buried deep underground, since the fungus, which may perhaps be already on it, readily grows luxuriantly in the open air. We should never throw out dead bees near an apiary, but bury them, as the dead bodies of bees are also soil in which fungi will thrive. As a corpse, if permitted to lie unburied, might infect a whole town and engender within it a fatal epidemic disease, so may a few putrefying maggots poison a whole apiary.

Should the disease have already broken out, it may be asked, What farther is to be done? In the first place, let us not take it easily, but view it with the same serious attention as is wont to be bestowed upon glanders among horses. That we must avoid all the before-mentioned food, either fermenting or capable of fermentation (among which meal should be reckoned) is, of course, self-evident. Medicaments for the extirpation of foul brood there are none. It is, as with the diseases of men, important to know this, lest time should be wasted in needless quackery. But as there are no medicaments for the disease, the maxim of Hippocrates must needs be valuable:—*Quæ medicamenta non sanant, ferrum sanat; quæ ferrum non sanat, ignis sanat*. We also pass quickly to the iron—i.e., we examine the hives diligently, and as soon as foul brood appears in the apiary, cut out every comb in which are foul-broody cells. If this is of no avail, the court of third instance—the fire, comes in its turn. We do not spare our apiary, but remove each foul-broody comb, disdaining to take from it either honey or wax, with which we should reap billions of foul-brood fungi, but throw it into the fire, wherein the fungi are effectually disposed of, and hang the healthy combs in pure hives. We do not deem it necessary to burn the infected hives, but wash them inside and out with diluted sulphuric acid (one part acid

to ten parts of water, by weight), and some time afterwards with boiling water, by which means the fungi are destroyed. If we prefer a self-acting process, we place the hives in an oven, and keep them there for some hours exposed to a temperature equal to that of boiling water; here the heat penetrates into all the crevices and pores, and effectually destroys the fungus. When, thirty-five years ago, I walked the hospital in Berlin as a young medical student, puerperal fever and hospital gangrene prevailed to a fearful extent, and the women and the wounded perished from ulceration, after enduring the most horrible sufferings. All remedies and precautions having proved futile, we emptied the different wards, keeping them for weeks with closed windows, heated to a temperature of 40° (123° Fahrenheit), and when they were again tenanted by the sick it was found that the epidemic had vanished. Here, then, also we may presume that a fungus was destroyed by the heat.

The site of the apiary should be repeatedly moistened with diluted sulphuric acid, and the earth around it dug over. After all the hives are purified, we should, if possible, remove the apiary to a new position. The conveyance of the disease by the bees themselves is perhaps less dangerous, if we only diligently examine their hives; and for this reason we only kill them when everything else fails. Their establishment in new, or at any rate clean, hives, is best effected about the middle of June, because they are then able to build sufficient combs and store them with food for the winter. But all *foul-breeding colonies should be transferred as nearly as possible at the same time*, lest the healthy stocks become contaminated by the diseased ones. For this reason also we examine all the combs weekly and remove such as are infected, and in this way it is quite possible to conquer the disease.

As in medicine the most distinguished practitioners generally discovered the right mode of treatment before the actual nature of the disease was determined, so also Dzierzon, von Berlepsch, and others have already promulgated many of the above rules for the treatment of foul brood, and have especially warned us against losing time in worthless quackeries, a warning which we cannot here repeat too forcibly. If, however, the instructions which we have given above be scrupulously and energetically followed out, no one need despair of curing the most virulent foul brood.—Dr. PREUSS, *Sanitätsrath*.

BEEES IN SOMERSETSHIRE.

THE experience I have gathered in sixteen years, though much of it of an old-fashioned sort, may interest some of your readers; my failures also may possibly prevent one or two from being disheartened, and encourage them to try again.

To begin at the beginning of my bee-keeping. The previous tenant of the premises, to which I came in 1852, left me a stock of bees in a very good Nutt's collateral hive of three boxes. They had occupied this hive for three or four years, and had never done more than fill the central box and build a small piece of comb in one side box. I found that the slides between the side and central boxes had always been open, and thinking that the temperature of the hive had been thus kept too low, I closed them, and the bees at once began to work in a glass super, in which during the July of the same year they stored 16 lbs. of honey. They gave me the same, or perhaps a rather heavier quantity in the following summer; but directly side communication was opened work in the super ceased, and they never showed any disposition to avail themselves of the additional room afforded by the side boxes.

During the years 1851 and 1855 these bees neither worked in the super as before, nor gave any promise of swarming; and as they seemed dispirited besides, and growing weak in numbers, in April, 1855, I turned them out of their box into a straw cottage hive partly filled with comb, and fed them liberally with the little honey that remained in their own stores and with sugared beer. They thrived very well in their new abode, and having, I suppose, reared for themselves a new queen, became very strong before the winter. In 1856 they threw an early and large swarm, which I secured in one of Neighbour's improved cottage hives. In the autumn I drove the old stock and added the bees to the swarm, and so made a very strong hive. I thus obtained the stores of the old stock without using brimstone, much to the surprise of many of my neighbours, and did not scruple to take also three glasses of honey from the cottage hive. My plunder amounted to more than 30 lbs. of beautiful honey.

I may just notice here that the transfer from wood to straw

had a wonderfully beneficial effect on the temper of these bees. So long as they were domiciled in Nutt's box hive they would allow no one to go near them, and many a time my gardener might be seen with his head sheltered in a bush, waiting patiently till his tormentors left him. After, however, they had been removed to the straw hive a total change came over them; they seemed to have lost their former irritable temper, and even children might play close to their hive unmolested.

The spring of 1857 found the inmates of Neighbour's cottage hive strong and active. They yielded me four small glasses and one large glass of honey, in all upwards of 40 lbs. The whole of this honey had a very strong flavour of rosemary. A very large plant of this shrub had blossomed profusely, and so strongly was all the honey which I took this year impregnated with it, that many persons found it very disagreeable to their palates.

In 1858 I purchased a strong stock and had another given to me, and, with the addition of these, and a splendid swarm from my own bees, my number of hives was now four. All of these I placed under a shed, and obtained several small glasses of honey, but on the whole the year was not to me a good honey year; still the stocks were all of them strong in the autumn and passed the winter well.

In the summer of 1859 three of my four hives swarmed twice each. One sent out one large swarm, and this latter another. Thus my total number of hives mounted up to twelve, all the bees worked well throughout the summer, and from some I took bell-glasses of honey, of the weight of which I have no memorandum. Why I acted as I now did I cannot tell. I did not, as I ought to have done, drive any of my bees; but over-persuaded by my gardener and an old parishioner, I was foolish enough, and mad enough, and cruel enough to destroy four stocks by the brimstone match, and so I received more than 80 lbs. of honey, for which I obtained a good price, besides a considerable quantity of wax.

In 1860 the tide turned—what else did a bee-destroyer deserve?—no swarms, no honey, and in the spring of 1861 every stock died. My vexation and grief may be more easily conceived than described. I could not but feel that my losses arose from my own stupidity and carelessness, and that if I had but used my own experience and a little common sense the case might have been very different. My garden did not seem the same with its flowers almost beless. The loss of the cheerful lively hum took away from the brightness of many a gay spring and summer day. I was thoroughly cured of bee-destroying, I hope for ever, and so, I believe, was my gardener factotum.

So passed 1861 and 1862; but in 1863 a neighbour, to whom I had been able to render a little service, most kindly sent me what he knew I would value—a strong and early swarm housed in one of my flat-topped straw hives. This stock did well and passed the winter safely. My previous experience had quite convinced me of the advantages which must arise from the use of some form of hive which would allow more complete control of the bees, and more easy inspection than is possible with the straw hive of the usual shape. The best I could hear of was the American bar hive, and I therefore procured one from a very respectable and worthy old man named Downie, at New Barnet. I afterwards procured others from him, but, as will subsequently appear, inconvenience arose from their not being all made to scale, and also from the width of the bars being slightly too great. This, however, was my first acquaintance with the moveable-bar system; and when in 1864 my bees swarmed, I at once introduced them into the American box. The swarm had settled on a Currant bush. I placed the hive, removed from its floorboard, above them, and they at once ascended into it. This swarm was a very strong one, and worked better than any other I ever had. On the twenty-first day from that on which they were hived I removed a super of 16 lbs. nett of beautiful honey, and afterwards they filled a smaller glass, which I allowed them to keep for their own share. The parent hive also gave me a glass of 14 lbs. in weight.

In 1865, I had no swarms, but a very large supply of honey, nearly 50 lbs. from the two hives, and all this of the most beautiful description. Many of my parishioners now began to take much interest in the way in which my bees were worked, and would frequently ask to be allowed to look into the window at the back of the American box, though they could see very little there, and the sight of the bees at work in one of the glass supers never failed to afford the liveliest pleasure. I was also very glad to show some who were anxious to try the plan, how to place a bell-glass on the top of their own hives, by simply

cutting out part of the hive with a sharp knife, and either placing the glass directly on the hive, or, as is better, using a small adapting-board, with a hole in its centre, between the hive and the glass, by which means the glass when filled is removed with the greatest ease, and without any risk of breaking down the comb.

I began 1866 with two stocks, both of them very strong. I had procured, as already mentioned, other two hives from Mr. Downie, on what he called the American-bar principle, unfortunately not made exactly to the scale of my first one, in preparation for the swarms which I anticipated from my stocks. When the looked-for swarms issued I was travelling with two pupils, who used to accuse me of always being on the look-out for bees, and of wanting to enter every cottage garden where we saw any. [We were walking through Normandy, and saw some wonderful stores of honey, and very neat cottagers' apiaries], and on our return home, I found my new swarms housed in the old straw hives, with plenty of cross sticks stuck through them. My factotum, not, alas! the one who had been with me in my former bee experiences, did not feel equal to doing anything with the new-fangled boxes, though he had received full instructions as to what he was to do, and a villager, great about bees, to whom he applied for aid in the emergency, condemned them *in toto*, put plenty of cross sticks into the old hives, and so hived the swarms. Of these swarms two issued on one day, and went together, and so made one monster swarm, so large that it filled not only a large stock hive, but also the greater part of the super hive which I use to cover the bell-glasses with. The second swarm from one hive was also unusually strong.

A few days after my return home early in June, I had my second bitter experience, from the perpetration of a stupid blunder. A strong swarm issued from the large swarm which I have mentioned above, and which I had immediately on my return confined entirely to the stock hive, allowing only a large bell-glass, and not the whole super for them to work in. I took this swarm into a common straw hive, since it was not convenient to place the bar hive above it, as I had done on a former occasion. In the evening I placed the bar hive on a clean cloth, propped with two or three pieces of wood, and dashed the bees out on the cloth in front of it. In a short time they were all quiet in their new home; indeed, when once the ascent began, it was interesting to notice the regularity of their march.

So far well. Now followed my blunder. As soon as the bees were settled and quiet, I placed perforated zinc ventilators on the top of the box, and closed the entrance also with a perforated zinc slide. I did this from a wish to prevent the bees from flying back, as many usually do in the morning, to the place where they have alighted, an object, which as I now know, is accomplished by placing a new swarm in its intended position as soon as possible after it has been hived. After thus shutting in the bees in order, as I hoped, to cause them to settle to work more readily, I placed the box in its intended position, and did not visit it again till nearly twelve o'clock on the following morning. I then opened the entrance with all due precautions against a fierce onrush of eager multitudes, but there came no rush, only a feeble stagger of about a dozen dripping bees which fell to the ground at once, utterly unable to fly. I had wanted to be wiser than Nature. I hope for the future to follow, not to seek to direct. Immediately I took off not merely the zinc ventilators, but the whole top, and then I saw a miserable sight indeed. Between the moveable bars the bees were lying dead in a mass, and that mass nearly 4 inches deep. They had been stifled in a worse than black hole of Calcutta. Here was an evidence, the strongest possible, of the intense heat engendered by bees at swarming time. When I had removed all the bees I found the whole box apparently saturated with moisture, dripping with wet, and yet there was more than double the ventilation there was in the hive from which the swarm had issued. I suppose from crowding round the exit in the morning, and being unable to pass out, they had choked the entrance, and so vitiated the air more than the little circulation at the top only could purify it. With much self-reproach and many resolutions of letting well alone for the future, I buried the victims of my ignorance, and I watched all the more anxiously my surviving stocks, all of which did well, and passed the winter unharmed, so that I have now to begin upon my Ligurian experiences, which date from 1867.—A SOMERSET VICAR.

HOMING PIGEONS.—On Thursday morning, Mr. Popplestone, station-master at Starcross, received from London per rail in a

tin box six Carrier Pigeons, which had been sent by a member of a London Pigeon Club, with the request that the birds might be set at liberty the same morning at 9.30. The request was complied with. The birds hovered over the Exe estuary, flying round and round for the purpose of ascertaining their whereabouts, and whither to direct their flight. At the end of that time they seemed to have satisfied themselves of their position, and darted off in the direction of Woodbury Hill, across which they were seen winging their rapid flight. Mr. Popplestone, we are informed, received a letter from the sender of the Pigeons on Friday morning, stating that one bird returned to its loft at Clerkenwell at 1.35 p.m. the day before, four others were found in the loft at two o'clock, and the last made its appearance a few minutes later. The Pigeons were only six months old. Between London and Starcross the distance by road is about 180 miles, which one of the Pigeons must have accomplished in little over three hours and a half.—(*Exeter Gazette*.)

OUR LETTER BOX.

BOOKS (Brahma).—You can have "The Poultry-Keepers' Manual" at our office. It contains sound information from none but practical men. You will see an answer about roup given to-day to another correspondent.

SILVER-SPANGLED HAMBURGS' FEATHERS (J. W.).—The feather you sent is a foul one, and does not belong to a Spangled Hamburg. It is the result of some distant cross, or of breeding out for want of fresh blood. On no account breed from such a bird. We would not use a wry-tailed cock. We have long known that defects are more certainly and more easily transmitted than merits or virtues. Wry-tail and crooked backs are among those that are certain to be reproduced.

WEIGHT OF BUFF COCHIN COCKEREL (Lenon Duff).—Ten and a half pounds at seven months old are more than a good weight, it is uncommon at the age, being growth at the rate of 1½ lb. per month. Cockerels still grow after that age if they are kept from the hens; but if they run promiscuously they fatten, but become little larger or heavier after eight months.

BREEDING AGE OF A GANDER (H. F. C.).—The gander of last May should be all you require for next season. They are capricious birds, and will not sometimes take to their Geese. Where that is the case get rid of the offender, and buy or borrow another.

FARNWORTH POULTRY SHOW (F. E. R.).—We printed the entire prize list. If you write to the Secretary he might tell you about the Turkeys.

ROUP (G. H.).—Wash the head daily, or twice daily, with tepid water; Sulphate of copper, one grain, daily, mixed in oatmeal mashed with ale, and plenty of green food. Separate the fowl from all others. If not better within a week kill the fowl.

DUCKWING GAME BANTAMS (Cousin Ad.).—Look to the prize list of the Chelmsford Show in our last number. Prices vary with the degrees of excellence.

BRAHMA FOOTRAS NOT ROOSTING (J. M.).—The roo you describe is an excellent one. The birds you have bought, have probably been accustomed to roost on the ground. They will take to the perch after a time. They do not require straw, it only serves to harbour vermin. The only nest they will require are some square pieces of plank nailed to the wall. The earth will form the bottom of the nest while the hen lays, and it should be the same when she sits. The piece of wood to form the nest may be 12 inches every way; such pieces nailed to the wall at distances of 12 inches will make the nests; a little straw should be put in the nest, and it is well to have a head to prevent the eggs from rolling out.

FOWLS TRESPASSING (J. H. P.).—Your Bantams going into your neighbour's garden and scratching there, or even going there without scratching, commit a trespass; and if sued in the County Court you would be liable to a fine and the costs. You must either confine your Bantams, or have a wire-net fence so high that they cannot fly over it.

MR. PETTIGREW'S LARGE HIVES (C. M. Major).—Twelve inches deep by 15 inches, 18 inches, and 21 inches in diameter, according to circumstances. We hope shortly to be enabled to give some details of his mode of managing these apparently huge hives from Mr. Pettigrew's own pen.

BEES IN STEWARTON HIVE (A Subscriber).—If the bees did not extend into the second box, and that not having any comb in it, remove it for the winter. If the upper box, even, has not been filled with comb, the swarm could not have been "a strong one," as supposed, and we would advise feeding.

CANARIES' TAIL FEATHERS DENT (T. C. C.).—The tail can be brought straight again by dipping it in hot water; but it will in all probability assume its proper shape as it grows to maturity. When a young bird damages any portion of its tail, pull the latter entirely out. If the birds be kept in a large cage, three sides wood, with the perches screwed to the back, and not touching the wires, they will not rub their tails.

FOOD FOR EXHIBITION CANARIES (Idem).—"Canary seed, 1 lb.; Summer rape seed, 1 lb.; linseed, 1 lb.; groats, about 2 ozs., mixed, and chopped eight times a week, are all that are required for conditioning birds.—W. A. BLAKSTON."

COUVE TRONCHUDA.—"E. D." wishes to be told how to cook the mid ribs of the large leaves of Couve tronchuda. His cook cannot make them tender, and especially asks, Are they to be peeled?

From observations taken near London during the last forty-one years, the average day temperature of the week is 53.7; and its night temperature 37.3. The greatest heat was 64°, on the 2nd, 1857; and the lowest cold 22°, on the 1st, 1866. The greatest fall of rain was 0.98 inch.

MARKET GARDENING ABOUT LONDON AND PARIS.—No. 1.

REMEMBER, in my former parish, a poor widow once consulting me with regard to a proposal she had had from a neighbour, who bore an indifferent character, and was reputed to be a drunkard. She spoke very wisely and well on the subject; she told of the comfort it would be to her to have a home, if it were a respectable one, and to have a protector for her children: "but, then, you see," she said, "W——'s character is a bad one. I know him to be a tippler, and there's no reason if there's a fire in the grate that I should put my head into it." Need I say what my strong advice was? and need I add that like most good advice it was set at naught, and that years of wretchedness and misery have resulted from "putting her head into the fire?" I was similarly situated when I saw the discussion going on in the horticultural journals relative to the market gardening about Paris as compared with that in the neighbourhood of London. I very wisely determined to keep clear of it. I thought that I was not altogether ignorant on the subject, and had some opportunities of judging as to the correctness or otherwise of some of the statements made, but the fire was "vara hot," and I did not fancy putting my head into it, and so I kept clear, gave the combatants a wide berth, and held my peace. Why, then, have I done otherwise? Why, like my poor friend, am I now about to put my head into the fire? If I have done foolishly, the saddle must be put on the right horse—viz., the Editors of THE JOURNAL OF HORTICULTURE.

It fell out on this wise. I was paying my annual visit to Paris in June last, a little later than usual, when, one afternoon calling at Vilmorin's, and inquiring for M. Henri Vilmorin, I was told he was gone to see one of the Editors: through their kindness a message was sent to him, and the next morning I found him in the courtyard of the Hotel de Saxe. We had much discourse together, and, naturally, it turned on those subjects dear to all readers of the Journal: amongst other points talked upon was the stir that had been made on the subject of market gardening in England and France, or, rather, in and about the metropolitan cities of both countries. The upshot of it was that I was asked, as I had a few days on hand, to employ a week in visiting especially those places of culture most likely to be interesting to us, and report accordingly. The task was a congenial one, the work pleasing, and I entered upon it *con amore*; if, in so doing, I bring down evil upon my own head, I must ask my good friends the Editors to help me to bear the blows. In so doing, however, I must beg it to be distinctly borne in mind that I enter not on it in any controversial spirit; I have but one object in view, and that is the good of horticulture. I have no theories to uphold, and, I hope, no prejudices to overcome. Such are my credentials, and now as to my qualifications.

The readers of THE JOURNAL OF HORTICULTURE know tolerably well that I am no tyro in gardening; that although I have mainly given my attention to florists' flowers, I

have also made myself acquainted with most branches of gardening; and that for many years I have been in the habit of visiting all the gardens, both public and private, which I was enabled to do in my frequent wanderings through England. I have seen in the gardens of our nobility and gentry, and in the well-ordered establishments of our public growers, the various plans and methods of cultivation adopted. During the past ten or eleven years I have also visited the Continent annually, have seen what gardening is in France and Belgium, and have been enabled to form some notion of its merits. I have not thus to contend with the difficulty that often surrounds a person who makes a first visit to a new country, who either goes with the belief that nothing is good but what is English, and who grumbles and growls to his heart's content over these "furren" ways, or who is prepared to see everything *couleur de rose*, and to come home with the idea that in everything they "do these things better in France."

I was not, however, satisfied with my previous knowledge, but felt that in writing on such a matter I ought to be as much at home as possible; and so, immediately on my friend's suggesting this, I started off to Vilmorin's, and told them my object, asking them where I should best see the various objects of culture which I desired more especially to report upon. With that urbanity and kindness which I have always experienced in France, and almost always in England, from members of the gardening profession, they not only offered me every information, but in order to place me more *au fait*, they put at my disposal one of their *employes*, who accompanied me on my visits, found out, as I could not have done, the readiest ways of access, and to the intelligent guidance of M. Viret, I owe a great part of the information which I obtained. When I say that, amongst other places, we visited together the establishments of L'Herauld at Argenteuil, Lepere at Montreuil, Froment at Montrouge, Dupont at Cliehy, &c., it will be seen that we went to head-quarters at once for our information, for each in his particular line is unsurpassed. I found the workmen generally intelligent and ready to give information; although amongst the *championniers* I do not think I should have got quite so ready an access to their places of cultivation if it had not been for my companion, and this I could well understand, for it involves considerable time and trouble. On my return to England I thought I should make myself more acquainted with the market gardening about London, and on applying to one whom I thought ought to be able to give me information, I was told that I should find the growers not nearly so willing to give information as their French brethren; that they thought more of their time, &c. I am bound to say I found it the very reverse, they were exceedingly kind, and gave me every information in their power. Here, too, I went to head-quarters—Mr. Dancers' fruit garden at Chiswick, Mr. Myatt's at Deptford, the Fulham grounds, &c., have all been visited by me, and I have been enabled thus to institute comparisons between the most eminent growers in both countries. Whatever errors, then, I may fall into, and whatever incompleteness of information I may be

guilty of, must arise from my own stupidity, and not because the sources of information have been unvisited, or those who were able to give it churlish in so doing.

I have felt it necessary to make these few preliminary remarks as due to the readers of *THE JOURNAL OF HORTICULTURE* and myself. There are some other preliminary observations which I must make as bearing generally on the subject of market gardening in England and France, but I would rather reserve them for my next paper, and I shall be then more ready to enter into the details of the various "cultures" on which I wish to report.—D., *Deal*.

A SELECTION OF ROSES.

As the catalogues of Roses are generally long and bewildering, and as the new Roses sent out annually are to a great extent worthless, it may be of service to persons unacquainted with Roses to give a selection of the best, and of such as are good growers, of hardy constitution, and free and constant bloomers. I am now about to speak of Roses on the Manetti stock, unless otherwise specified.

HYBRID PERPETUALS.—For beginners—Achille Gonod, Alfred Colomb, Anna Alexieff, Antoine Ducher, Baron Adolphe de Rothschild, Baronne Prevost, Caroline de Sansal, Charles Lefebvre, Comte de Nanteuil, Duc de Cazes, Exposition de Erie, John Hopper, Jules Margottin, La Ville de St. Denis, Lord Clyde, Madame Alfred de Rougemont, Baronne de Maynard, Madame C. Crapet, Madame Clemence Joigneaux, Maréchal Vaillant, Madame Boutin, Marguerite de St. Amand, Maurice Bernardin, Prince Camille de Rohan, Sénateur Vaisse, Souvenir de Dr. Jamain, Triomphe de Paris, Victor Verdier, and William Griffiths.

The preceding are beautiful Roses, and, if beginners cannot cultivate them successfully, the sooner they take to cultivating something else the better.

For older hands I add Abel Grand, Alpaide de Rotalier, Baronne Pelletan de Kinkelin, Black Prince, Charles Bonillard, Charles Verdier, first-rate, Comtesse de Chabillant, Dr. Andry, Duchesse de Caylus, Duchesse d'Orléans, Empereur de Maroc, Eugène Verdier, François Lacharme, Gloire de Ducher, Gloire de Vitry (on its own roots), a noble Rose; Jean Rosenkrantz, John Keynes, Monsieur de Montigny, a noble Rose; Lady Suffield, La Duchesse de Morny, Leopold Premier, Lord Macaulay, Madame Alice Dureau, a beautiful first-class novelty in the style of *Lælia*, Madame Rolland (not the same as Madame Roland), Madame Charles Wood, Madame Emile Boyau, Madame Freeman, Madame Julie Daran, Madame Knorr, Madame Victor Verdier, first-rate; Pierre Notting, first-rate; Prince de Portia, Sœur des Anges, Souvenir de Comte Cavour, superb, but not full; Souvenir de la Reine d'Angleterre, and Vicomte Vigier.

I now put down two unsurpassed Roses, but they are delicate, and require genial situations and first-class loam—they are Madame Rivers and Madame Vidot.

I am very averse to recommending Roses that I have not fully proved, but I fancy we shall eventually find some good Roses among the following:—Paul Verdier, Monsieur Noman, La France, Marie Cirilde, Prince Humbert, Reine du Midi, Pelix Genero, François Treyve, Marie Baumann, Mlle. Jeanne Marix, Madame Martine de Besse, and Merveille d'Anjou. I also fancy these three of this year's novelties—Monplaisir (Tea), and Hybrid Perpetuals Madame Jacquier and Thyra Hammerick.

BOURBON AND CHINA ROSES.—These are scentless Roses, and I will only put down distinct and essential ones.

BOURBON—Acidalie, Baronne Gonella, Souvenir de Malmaison; and for poles, Sir J. Paxton.

CHINA.—Mrs. Bosanquet.

PERPETUAL MOSS.—Madame E. Ory.

TEA-SCENTED NOISSETTES, a noble class.—Solfaterre, south wall; Gloire de Dijon, Céline Forestier, Triomphe de Rennes, Maréchal Niel, a noble Rose, requires a south wall. For beginners Gloire de Dijon is best.

TEA SCENTED ROSES.—For beginners Sombrenil, Devoniansis, and Rubens. For others, Adam, Homer, Madame Margottin, Madame Willermoz, Souvenir d'Elise, first-rate; Bouton d'Or, first-rate for lutton-holes, and Souvenir d'un Ami. For glass, Elise Sauvage, Madame Bravy, and Vicomtesse de Cazes.

Tea Roses are in their proper place when under glass. No Roses are superior to them for this purpose. They may be grown under a south wall. They require but little pruning, good drainage, high cultivation, plenty of water, and great heat.

Hybrid Perpetuals, Tea-scented Noisettes, and Tea-scented Roses are the best three families, and they are rapidly and justly superseding all others.

We have had a trying season, and it may help purchasers if I give the names of those Roses that have beaten everything here this year. These are:—Charles Lefebvre, Jules Margottin, Duchesse d'Orléans, Sœur des Anges, Baronne Prevost, Monsieur de Montigny, Marguerite de St. Amand, Madame Knorr, Gloire de Vitry, Isabella Gray; in the open ground, Gloire de Dijon, Céline Forestier, Triomphe de Rennes, Sombrenil, Elise Sauvage, Devoniansis, Rubens, and Souvenir d'Elise, a most beautiful Rose. Others have done well. On the whole I have had a splendid season. It is almost impossible to conceive or describe the magnificence of the first series of flowers.

I advise persons about to commence Rose-purchasing to find out what are really good, and accumulate them rather than heaps of Roses erroneously termed varieties. The variety consists in the name. Begin with fifty or a hundred each of Charles Lefebvre and Jules Margottin. These are every-day and all-the-season Roses. They always open, and never have a defective bloom. The same may be said of Gloire de Dijon, Céline Forestier, and Triomphe de Rennes.

I have discarded some Roses here, but I have filled up their places with well-known good kinds rather than with unproved novelties. The best novelties that I have had of late years are Alfred Colomb, Charles Verdier, Antoine Ducher, and Prince de Portia.

One more word and I have done. I expect a severe winter. It generally is the case that the winter is cold in proportion as the summer is hot, for the going-out of heat is equal to its going-in. All my Roses are mulched with stable litter or straw; and by November 8th they will be earthed over the straw or litter, and present the appearance of plants in molehills.—W. F. RADCLIFFE.

FIG TREE CULTURE.

THE past summer in England so closely resembled in its high temperature the south of Europe, that it was peculiarly favourable to the development of such a crop of Figs as is very rarely to be seen in our changeable climate. Nor has the abundance of this singular fruit been confined to one or two favoured localities, but wherever the trees escaped injury from the severe frosts which occurred during the winter of 1866, or rather in the early months of 1867, fine crops of well-ripened fruit have been produced, and in some gardens having one or two of those enormous old trees which are occasionally to be met with planted in the most sheltered corner, the ripe fruit has been gathered by bushels. In these cases how little has science to do with the matter. I once saw some very fine fan-shaped trees beautifully trained, and most rigorously pruned on the spur system, and I was curious to know whether trees so treated in the open air would produce fruit in any quantity; but on making inquiry, I was told that but little fruit was ever ripened, certainly nothing ever approaching what might be considered a full crop. Since then I have met with several instances in which close pruning had been practised, and in every case the result was the same—but little, if any, fruit. From my own experience, I should say that moderate pruning, just sufficient to keep the trees within bounds, is by far the best plan, and even this may be effected in a great measure by pinching during the growing season. Trees so treated, and planted in a somewhat poor and shallow soil, will generally produce a fair crop of fruit.

Perhaps the most tantalising thing in connection with Fig culture in the open air, is that second crops are always most abundant and full of promise, but never coming to perfection, or at all events but very rarely. How it makes one long for the sheltering roof of an orchard house! What dishes of the luscious fruit could then be had for the dessert at this dull season of the year, when anything affording variety is so much appreciated!

It would be interesting to know how far the second crop has been affected by the heat of the past summer. The only instance in which I have heard of the second crop coming to maturity, is at Provender, near Faversham, the residence of the Dowager Lady Knatchbull, whence Mr. Maxted, the gardener wrote to me on October 15th, saying, "We have a fine second crop of the little Early White Fig, just fit for table." This is all the more interesting, as the trees are not on a wall but are bush-shaped, about 10 feet high. They are growing in a warm sheltered position facing the south. I believe I am right in stating that these trees are never pruned, but as they have no

protection whatever during the winter, the tips of the young branches are frequently killed by severe frost. This causes the buds at their base to start into growth, and the trees consequently become more bushy and compact.—EDWARD LUCKENST, *Egerton House Gardens, Kent.*

FUCHSIA RICCARTONI.

AMONGST the plants whose growth or flowering has been interfered with by the heat of the past summer, the useful, hardy *Fuchsia Riccartoni* is one having a sturdiness of habit and deep-rooting propensity which would seem to render it safe from drought; but such has not been the case here, for some large old plants, of which the last year's stems had not been injured by the winter's frost, and with roots occupying a border that has been worked upwards of 6 feet deep, being, in fact, part of an embankment of that height, nevertheless showed signs of distress much sooner than might have been expected.

The plants flowered much earlier than usual, but the amount of bloom, and the length of time they continued in flower, fell far short of what might be expected of bushes upwards of 6 feet high, and as much in diameter. Their flowering seemed to be quite over by the middle of July, and by the 1st of August the foliage had assumed quite an autumnal appearance; but some rain which fell about the middle of August infused new vigour into the plants, fresh foliage was produced, and although much growth has not been made from the middle of September up to this time (the middle of October), the plants have been a mass of bloom. The flowers appear to be produced at every eye of the shoots made prior to July, rather than on those of recent growth. This is certainly an unusual case, but it might have been explicable enough if the plants had not had a sufficient amount of room for their roots, but as they had a depth of from 6 to 8 feet of soil, and that mostly of a suitable kind, I can only conclude that the extreme heat, and the deficiency of moisture in the atmosphere, caused the premature ripening of the shoots, which afterwards broke forth in flowers much in the same fashion as Potatoes have produced a second crop of tubers from the first. The situation was dry, and no water was given, but surrounding the *Fuchsias* was a carpeting of seedling *Petunias*, which did not seem to suffer, neither did the edging of *Centaurea gymnocarpa*. Doubtless, the *Fuchsias* require more moisture than either of the latter: hence the failure of the *Fuchsias* at the time they are usually at their best; but I am by no means dissatisfied with the result, for an autumn display is as useful as an August one, and they promise to supply that as long as the weather will permit.

Notwithstanding all that has been done in supplying our plant houses with improved varieties of *Fuchsias*, it does not appear that any one approaches *Riccartoni* for out-door display. The raiser of this old favourite has, therefore, something to be proud of, if he is yet alive; for a plant maintaining its position for thirty years in an age when the most approved variety of one season is superseded the next, is seldom met with among garden flowers. This old *Fuchsia* seems likely to continue for many years at the head of those for out-door cultivation, for if there is a better, it seems not to be generally known, and those possessing such would do good service by stating its name and merits.—J. ROSSON.

A GRAPE VINE AFTER TWENTY YEARS ON THE EXTENSION SYSTEM.

IN the spring of 1813 I put in some cuttings, from 15 to 18 inches long, of Sweetwater and Black Hamburgh Vines at the bottom of a south wall and round the borders of the kitchen garden, my employer being sanguine of carrying out the idea of growing Grapes here (West Kent), as well as on the Continent.

Along with the cuttings put in at the bottom of the wall, there were two small rooted plants. One, which proved to be a Black Hamburgh, was trained as a single rod, between two Peach trees, to the top of the wall, then along under the coping, where, in 1851, it ripened partially about a dozen bunches of Grapes. I then took the Vine from the wall, and layered it across the border into a turf pit, covered with glazed sashes, that had been used to winter bedding plants. There, in 1862, the Vine ripened nearly a hundred bunches with sun heat only. The place then passed into other hands, and I had the space between the pit and the wall covered with glass, thus giving the Vine room to extend itself, and it now covers about 300 feet

of glass surface, and but for the limited space allotted it would have covered a much larger extent. It bears annually good crops, which ripen about the first week in June.

I would observe with respect to layering, that the thickness of the stem, or rod, has increased very little. Where it enters the ground it is only 3½ inches in circumference; where it rises it is 10½ inches.—PRACTICUS.

MUSHROOM CULTURE.

I HAVE frequently read with much interest the directions, hints, &c., on Mushroom-growing contained in "our Journal," and have, to the best of my ability, followed those instructions, but never with success. When I first commenced attempting to grow Mushrooms I felt certain of succeeding, having all things necessary, as I thought, immediately at hand. I have abundance of horse droppings, loose straw or litter, spare cellars of both dry and moist atmospheres, and good dark sheds, and I have tried spawn from several principal seedsmen in London, but my efforts have never resulted otherwise than in failure. If I could, through the medium of "our Journal," receive plain instructions from any amateur grower who has been successful, I might be better able to follow them than the course pursued by professional gardeners, and the first two dishes of Mushrooms I grow shall be distributed, one to the amateur, and the other to yourself, carriage paid.—K. J. R.

[We are very sorry that you have been so unfortunate in your Mushroom-growing, and the proffered reward is irresistible, but we are also sorry that you give us no information to enable us to be sure as to where the cause of want of success is to be found, and all the more, as you seem to have tried all that has appeared in our columns, and carried out all the instructions given, and yet without avail. As we would wish to have a fine dish of Mushrooms ere long, we will say a few words, first on the chief causes of failure, and then give a simple outline of one of the modes to be adopted to ensure success.]

The want of success is sometimes owing to bad exhausted spawn. The spawn when broken should be whitish inside, but the filaments should resemble the finest gossamer, or silky hair. If they are as large as a common sewing thread they are too far gone. It matters little about the age of the spawn if it is good and has been kept dry. We have used it seven years after making without any diminution of the produce.

Good spawn is often destroyed by being put into a bed of wet material, or into a bed too warm, or that becomes too warm after the spawn has been inserted. A bed over-dry is safer than a bed over-wet. In the first case you can water, or ease with a somewhat moist substance; in the latter case it is safest to wrap the spawn in a handful of loose broken dryish litter, and when it gets through that the dampish material will give substance to the Mushrooms.

The spawn will not stand long a higher temperature in the bed than from 70° to 80°, and an atmospheric temperature of from 55° to 60° is what it delights in, though with heat in the bed the fungus will grow freely at a lower temperature than that. The high temperature in the bed is one chief cause of failure. Another cause, sometimes, is mixing with the dung and soil something inimical to fungus growth. A friend of ours, to guard against slugs and worms finding their way into his beds, mixed quicklime with the fermenting material and soil; but if he destroyed the invaders he also destroyed the spawn and Mushrooms. We are not so sure of alkalis generally; but lime when hot is most effective in destroying all the fungus tribe. In earthing-up we prefer a loamy soil, even a stiff clayey loam, to one chalky or calcareous.

Mushroom beds fail, also, owing to want of patience in the cultivator. Sometimes they will produce in a few weeks, but from six to eight weeks is a very common time after spawning and earthing-up, and during all that time the more regular the temperature of the bed, and the less it is meddled with, the better for the coming crop. We have known beds spoiled by pulling them about, drenching them, and roasting them with heat either from fires or warm coverings, although they would have done well if merely let alone. The quickness of growth depends more on the condition of the materials than upon any other treatment that can be given. Patience must be exercised.

Now for a short outline of culture. We will not enter into various modes, nor dwell on the treatment in various places. We will fix on your cellar, and as winter is coming on, we will fix on the dry cellar, whilst in the summer we would have

chosen the moist one, for it will be easy to give what moisture would be necessary in winter; and as you want Mushrooms as soon as may be, to save time, we will only have a small bed at first, making up a piece at a time as you have the materials ready. Our bed we should propose to be 4½ feet wide, and from 15 to 18 inches deep, and if we could do no more we would begin with 2 or 3 yards in length at a time.

The first work to be done is to collect as many droppings, of which you have plenty, as will make a small bed. Add to them about one-fourth of the shortish litter. If the droppings are in the least too damp, spread them out, if convenient, in a shed to dry; whether convenient or not, ere long throw them into a heap, where they will heat violently, lose nutritive properties, but become sooner fit for your purpose. When heating, spread out again for a day. Add about one-sixth of bulk of rough fibrous loam, which is not absolutely necessary, but useful in preventing the mass heating too violently, and, therefore, losing heat altogether sooner. Throw all together into a heap again, and as soon as it heats begin to form your bed. We should, however, state here that during the summer droppings thus treated will be sure to heat themselves dry enough; and, as already stated, provided the strength is not wasted, it is safer to have them rather dry than rather wet. As October and November come on, even throwing the droppings into a heap will sometimes leave them too wet, which they always will be if you can squeeze moisture out of them. In such a case the evil may be remedied by chopping up a bundle of dry straw or litter, and mixing it with the droppings so as to dry them.

The droppings being all right, proceed with making the bed, and it will be best to put on a layer about 8 inches in depth at first, which will beat down to 5 or 6 inches, the firmer the better; and if well firmed it will not heat so strongly but that you may add another layer in a few days, treating that in the same manner, and then a third, reserving the best and shortest for this last layer, and making firm as before. The use of the beating is to keep out the air, and thus prevent rapid decomposition; and to insure this, in other words to prevent the dung being wasted before the Mushrooms feed on it, we frequently throw a little soil over the surface before the final beating, as there will be enough of air enclosed with the dung to keep up a long but slow decomposition, and therefore a somewhat low but regular temperature, instead of a great heat, soon gone.

After thus finishing off the dung bed, it wants watching with trial sticks every day. It is next to impossible, if thus formed, that it should not become warm enough—from 80° to 90°—and it will be better if the heat rise no higher. Even now you must not think of spawning, you must wait until the heat is on the decline, and when you find that every day it becomes a little lower, until your trial sticks are no warmer than new milk, or the thermometer plunged in the bed is scarcely above 80°, you can then spawn the bed. We prefer using pieces of spawn rather larger than green walnuts as they hang before falling from the tree, and we insert these just below the dung, and if we are sure there will not be too much heat, we scarcely cover them; these for a general bed we place about a foot apart. When we wish a quick return we place them more closely together.

If properly watched as above, there will generally be little danger after spawning, but a sudden change in the weather will often act on the bed, causing it to heat again more than we wish, and in other cases to cool more rapidly than we like. In the first case, the putting the spawn near the surface preserves it from danger. In the second place, being near the surface, we can add a couple of inches or so of nice hot droppings, which when beaten will cause the bed to heat gently again. As soon as danger from overheating is past, the sooner the bed is earthed the better. When we can obtain it we prefer fibrous loam beaten firm next the bed, and then a layer of finer-riddled soil on the surface. We use that rather damp than dry, and when all is well beaten we water the surface of the bed, and draw a clean spade firmly over it, which leaves a clean smooth surface. In general we use rather more than 2 inches of soil when loose, which when beaten will be from 1½ to 1¾ inch in thickness. In such a place as your cellar, we should let the bed stand as left for a day or two that the surface may become a little dry, feeling the trial sticks every day. In general the earthing-up causes the heat to decline, because the air cannot find its way into the bed.

When the heat falls a little, say 3° or 4° lower than when you spawned, cover the bed over with 2 inches or so of old hay or short dry litter, which will prevent the bed losing heat from the surface. If the heat still decline add a little more

covering, and this in general may remain for two or three weeks, but it must frequently be examined, for in the course of a month or so, if the spawn is working freely, so as to permeate the whole mass of the bed, that process will always be attended with an increase of temperature, and, therefore, that covering may require to be reduced. At any rate it would be advisable as soon as the first spawn begins to peep through the soil to remove all the covering, sweep the bed all over with a hair broom, and place fresh covering, or merely the driest of the old covering, over the bed. Under such circumstances we have always found that a little covering kept the temperature of the bed more uniform, and even the atmosphere about the Mushrooms on the bed was kept more genial as respects moisture and temperature than when the bed was fully exposed.

Thus treated the surface of the bed will often become warm when the spawn works, and whilst it should not be suddenly cooled, neither should it be allowed to become so warm as to injure the spawn. We believe many beds are injured by too much warmth and too much covering at such a time. We can scarcely dispense with this covering where no means are resorted to for regulating by artificial means the atmospheric temperature of the place.

Sweeping the bed, and using dry material as the spawn comes to the surface, are necessary to prevent the spawn running and exhausting itself in the damp covering. In winter it is safer for beginners to secure moisture by damping the covering, the walls, and the floor, instead of watering the bed overhead. At that season the watering will be little needed, but if the materials of the bed are dry it will be safest to make holes with a pointed stick, and then pour warm water into them.

For insuring Mushrooms quickly it is of importance to earth-up as soon as it is safe after spawning, as then, with the slight covering over the surface, the spawn when it works, ere long works upwards as well as downwards. To insure this still more, we prefer the soil next the dung not to be over-wet, even though we wet the surface to make it smooth as well as firm. The smoothness and firmness are good for the young Mushrooms showing, and the bed is easily cleaned.

If there are any little matters of importance that are omitted, we shall be glad to supply them when reminded of the deficiency. We would remark, in conclusion, that nothing more depends on attention to trifles than successful Mushroom culture.]

CHECKING EVAPORATION FROM THE SOIL.

No doubt various opinions will be entertained respecting this subject, to which attention was drawn by Mr. Fish some time since, but not having seen any further remarks as yet, I simply add the following, in the hope of eliciting a clear explanation from more experienced persons.

Most soils on becoming dry have a hard crust formed on their surface, varying in thickness according to the duration of the drought. In heavy, dry lands, deep cracks are frequently observed, caused by the particles of soil adhering more closely on parting with moisture. Is evaporation assisted or arrested by loosening the surface of the soil? or, in other words, will the soil become dry sooner by breaking through this hard crust or not? From observations during the past dry season, I am led to believe that the deeper the loosening, the quicker will the soil part with its moisture. On a newly-dug border fully exposed to the sun, a thin cake of adhesive soil was placed; in a few hours the sun's rays had penetrated inches into the loose earth around, while the under side of the turf was moist, and the soil beneath comparatively cool. Here the hard crust prevented both evaporation and the rays of heat taking effect. By loosening the surface of the soil you admit air, which, becoming heated by the sun, rises laden with the vapour from below.

Light soil, which seldom forms a crust, quickly dries up, through affording a free passage to air, and, consequently, to the ascent of vapour, while the heavy clay, impervious to heat and air, retains its moisture. Applying this to practice, when the ground becomes dry, and you cannot water, by no means break through the surface crust, but simply fill up the cracks, and hoe as lightly as possible, or, perhaps, hand-weeding would be better still.—NEMO.

[There is much force in some of "NEMO's" observations, and though in some parts he seems to agree with Mr. Fish, yet the conclusions at which he arrives are quite the opposite of Mr. Fish's. Mr. Fish says, page 152, "If we are right, the surface-stirring of ground to keep heat out and moisture in, de-

pende more for its effect on the frequency and the shallowness of the stirring than upon its depth." "Nemo's" conclusion is, "When the ground becomes dry, and we cannot water, by no means break through the surface crust, but simply fill up the cracks, and hoe as lightly as possible, or, perhaps, hand-weeding would be better still." This suggestion of hoeing is not quite in harmony with the previous words, "by no means break the crust." We do not allude to this little discrepancy at all in a carping spirit, quite the reverse, for, like "Nemo," we frequently find facts that militate against favourite theories.

We may be wrong, but at present we believe, that amid the drought we kept our flowers in beds alive by a very frequent shallow-moving of the surface with a Dutch hoe, and this not so much to fill cracks, as to prevent cracks being formed. Every such moving of the surface broke the lines of conduction and radiation, and even evaporation, and caused their work to begin anew. The fresh-moved loose surface acted very much in the same way as the cake of soil or turf placed on the surface of the open border. The more adhesive it was, the sooner it would be heated, and the more heated it was the more would that heat raise the moisture from beneath. It would be different as a conductor from a common caked, hard surface, as there would be air beneath it, unless beaten down very firmly. If the turf was firm, and covered a large space, cracking would soon take place, and nothing could be more injurious to plants, as this season, by means of thin laths, we measured cracks more than 4 feet deep, and there the heated, dry air could circulate at will. Wherever dry air can find its way freely, it will dry the soil with which it comes in contact. Hence, deep stirring in summer may often be unadvisable, and light soils may stand more in need of compression than of stirring them up to much depth. The fork is an excellent cultural instrument, but there are soils that will be the better of the roller. After the compression, it will generally be advisable to stir the surface.

It may help to elucidate the matter, to bear in mind that heat and cold are merely relative terms, and that what will heat admit or keep out the one, will also best admit or keep out the other. As a general rule, the firmer and the more compact a soil is, the more deeply will it be heated by the sun's rays, as the firmer it is the better will be its absorbing and conducting powers. The same rule holds good as to the depth to which frost will go. When our deeply-stirred loose soils become heated and dried in summer, it is less owing to direct absorption and conduction of heat, than to the free entrance of dry, heated air.

Again, when we ridge-up stiff soils in winter, it is not to enable them to part with their heat more freely by radiation and conduction, but that the keen frosty air may find its way to every cavity, and thus act as the best and the cheapest of all pulverisers. We think we told somewhere of the impression made on us, long ago, by the different results attending two small Potato pits covered with soil, and attended to in every way alike as to quantity of soil, &c., with only one little difference. One man, and a most careful tidy man he was, beat the earth quite firm, leaving a smooth surface. The other man piled the earth rather firmly, but left a rough open surface, showing nothing of the polish and finish given by his neighbour. A very hard frost set in in November. The pits were not opened until the new year. In the rough-surfaced one the Potatoes were all sound. In the polished-surfaced one, most of the tubers were sweet, and had to be placed in the coldest water for some time before cooking them. Whilst pondering on the fact of the difference, it was long before we could find a reason for that difference.

Whilst agreeing, then, with much that "Nemo" has stated, we must still value a loose fresh surface as a regulator of heat and moisture.]

PEARS FOR NORTH WALL.

In your reply to "H. W. B." on this point in answers to correspondents, October 8th, you remark, "No Pear succeeds well on a north wall." I confess I was staggered when I read this reply, and very humbly I must beg to differ from you. My locality is probably the highest village in Somersetshire, and we are colder than in many parts of the county, yet I gather very respectable Pears from my north wall—not, of course, what they would be on a south aspect, but still fruit that I should never object to eat.

When I came here first, I found the following Pears on my north wall:—Beurré Diel, Beurré de Rance, Forelle or Trout, Late Chaumontel, Winter Nelis, and Louise Bonne of Jersey.

Now, with the exception of the last-named Pear, none of these trees ever produced a ripe fruit. All, therefore, except the last, the Chaumontel, and the Beurré Diel, I had cut back and grafted with Williams's Seedling (Don Chrétien), Jargonelle, and Marie Louise. The Beurré Diel and Chaumontel do only for baking and stewing, but the other four Pears are all fit to eat; indeed, this year they have been first rate, and if "H. W. B." must have Pears on the north wall, let him try these, and I do not think he will be disappointed.—Y. B. A. Z.

[We were quite aware that Pears "fit to eat" may be grown on a north wall, but we do not consider that succeeding well.—Eds.]

THE GARDEN AT THE MOTE, NEAR MAIDSTONE.

In the midst of a park of more than ordinary beauty stands The Mote, the principal seat of the Earl of Romney. The mansion is one of those Grecian structures of which so many examples were erected about the beginning of the present century, and which are more remarkable for comfort and convenience than for ornamentation. The site is a slight elevation in a sort of valley formed by the river Len, which flows through the park, and in its course forms a large sheet of ornamental water in shape somewhat resembling the letter Y; but it is so judiciously managed that the whole of it cannot be seen from any one point of view. The park is several miles in circumference, and is well diversified, hill and dale alternating, with now and then the naked rock peeping out in places, while in others it is covered with the richest sward. The whole is plentifully studded with trees of great beauty, not indiscriminately scattered, but arranged to produce the best effect—in one place hiding the boundary where the object beyond is of no importance, but opening out in other directions where distant scenery can be advantageously brought in.

The great extent of the park, and its many features of interest, including a church in one place, a monument to commemorate a visit by George III. in another, its undulating character, and the lake, give it importance apart from outward attractions. And yet these are of no mean order. On the north-western side it is only separated by a public road from Vintara, also a highly ornamental park, while the southern extremity stretches almost into the town of Maidstone, of which the churches and other lofty buildings may be seen from many parts of the park. For the richness of its verdure and the variety of its scenery this park is exceeded by few.

The mansion is likewise sufficiently removed from the seats of industry and highways, so that one strolling amongst the groves at The Mote might easily imagine himself many miles from any town. There are no smoke-stained boughs nor dirty foliage to remind him that other habitations are near. On the contrary, everything seems to assume that healthy vigorous condition which is characteristic of a pure atmosphere and an excellent soil. That The Mote is thus favoured will be manifest by the following description of some of the subjects in the garden, as well as by the fine specimens of trees in the park, such as Cedars, Yews, and Thorns, together with plenty of indigenous trees of all kinds and recent introductions from abroad. The last-named are not too profusely interspersed, as it is questionable whether they will ever attain the beauty of form and large proportions which our native trees present. Attention has likewise been directed towards providing for the requirements of a future day, young trees being planted in suitable positions, and the whole attended to in that careful manner which is the best guarantee of success.

I have already stated that the mansion occupies a slightly elevated site about the centre of the park. The view to the south-west, down the valley of the Len and over the town of Maidstone, extends for several miles, not the least effective part being the park itself, with its broad expanse of water occupying the lowest ground, and the eminences mostly crowned with groups of trees in the healthiest possible condition. A large mass of trees, many of them of very large size, forms a background to the mansion, enclosing, as is often the case, the offices and back approaches, but in this instance also encompassing the kitchen garden and dressed grounds. The latter contain many beautiful green walks, bordered with shrubs, and overhung by magnificent Oaks and other trees. A large piece of woodland is also rendered very picturesque and interesting by this mode of intersecting it in various directions by beautiful green glades; and the visitor every now and then comes upon

some open spot, where an *Araucaria* or other choice tree stands out above the well-shaven turf, and in other cases the opening points to some important object. Near the mansion a large open space had been devoted to flower beds, but at the time of my visit some further additions had been commenced. It is, however, more especially to the kitchen garden that I would direct attention.

At an easy distance from the mansion, on the north-east side, is situated the kitchen garden, almost entirely surrounded by trees and shrubs, yet none of them sufficiently near to prove injurious by their shade. The space enclosed by high walls is about four acres, and there is a large plot adjoining the eastern wall of nearly the same size, with slips and other surroundings. The site of this garden, like that of the mansion, is a table land between two valleys, which unite at the ornamental water in the park; and this elevation ensures dryness, and no doubt to a considerable extent immunity from spring frosts, to the destructive influences of which the garden would be exposed if on a lower level.

Good walls 12 feet high, and in some places even of greater height, surround the principal garden, which I ought also to observe is nearly level, slightly inclining to the south-west perhaps. In shape it is not square, having, in fact, several corners, which afford many aspects for wall trees. The soil has long been the envy of neighbouring gardeners, being one of the very best of those resting on the limestone formation, for Kentish rag crops out in various places in the park and woods. I believe a considerable portion of the kitchen garden was once a quarry, and it is the debris from this, overlaid by an unusual depth of soil, that gives so much fertility to this garden. There are but few crops which do not thrive in it. Most fruit trees succeed remarkably well, and the same may be said of vegetables of all kinds.

Most of the walls which present a south, east, or west aspect are devoted to the culture of Peaches, Nectarines, and Apricots. Against the north wall were some magnificent Morello Cherries in condition for the dessert, for which, when well ripened, they answer very well, losing all the sharpness they possess when first ripened. These walls were covered with a fine description of hexagon netting to keep flies and wasps at a distance. Some choice Plums, such as the Washington, Jefferson, Coe's Golden Drop, and other varieties occupied a portion of an eastern wall, and where the crop had not been gathered the trees were loaded with fine fruit.

It is, however, more particularly to the Peach trees that I would call the attention of the cultivator, for they were all that could be desired by the admirer of that fruit, and were growing under circumstances in which of late years it has been asserted it is impossible to produce good Peaches; yet the result has been so successful that the champions of glass walls or glass houses must admit that their theory of the deterioration of our climate is open to considerable doubt, and that the old-fashioned method of growing Peaches will still maintain its reputation, despite the mass of new contrivances adapted for the same end at a cost at least tenfold that of the old system. The length of time during which Peaches have been so grown here, and on the same trees too, must convince the most strenuous advocate of glass that fine fruit can be produced without its aid; for although the Peaches were not so large at the time I saw them, the last week in August, as they had often been in former years, the healthy condition of the trees, and the abundant crops they were loaded with, showed that there was nothing wanting, except additional moisture in the ground and atmosphere, to have made them all they were in previous years. The wall was in all cases well covered, and the trees fruitful to the bottom; and although many of them were evidently very old, yet in most cases their trunks or collars did not show those symptoms of decay we so often meet with in aged trees.

Some of the trees occupied a length of upwards of 30 feet of the wall, which is 12 feet high, and one of them, a fine specimen of Royal Kensington [*Grosse Mignonne*], covered a space quite 40 feet by 12, and had in several years brought to perfection upwards of sixty dozen Peaches, more than seven hundred in a year. A fine specimen of Montanban was somewhat less, but also good, while Royal George, Noblesse, and Late Admirable were equally well represented, and had been bearing well for an average lifetime, for Mr. Luckhurst, the intelligent and energetic gardener, had managed them for more than thirty years, and some of them—the large tree of Royal Kensington for one—were not young at the commencement of that period. I understand that the tree just referred to is in a much better condition now than it was thirty years ago, and

judging from its appearance, it may, if no accident occur, last as long again, if proper care be taken, and the other conditions to its success be still afforded. As most of the trees against these walls were old, and the whole in good condition, the question naturally arises, how does it happen that we often meet elsewhere with Peach trees that seldom reach the age of ten years before they have to be replaced, having either fallen into a hopeless state of decrepitude or died? So very common is this, that many are of opinion that the seasons, which fifty years ago were favourable to the growth of the Peach out of doors, are no longer so, but that glass in some form is necessary. The trees here are a contradiction to that theory, so that we must look for another explanation of the fact.

The good quality of the soil at The Mote is doubtless one of the causes of the Peach doing so well at that place, but there are others, perhaps, still more important. The trees seem to be well managed and cared for: during the past dry summer when so many trees presented a foliage much of the hue of Golden-leaved Pelargoniums, the leaves of those at The Mote were mostly green; the syringe or engine had been timely at work to keep red spider down, and had accomplished its object; protection to the blossom in spring had also been afforded by means of broad projecting boards attached to the wall coping. These boards are 18 inches wide, and if the trees had not looked so well under them, I should have thought that keeping the boards on all the summer would have done harm by preventing dews and the midday sun reaching the upper part of the wall, but as the trees and their crop were so good, this opinion must give way before the facts. The boards form an excellent ledge from which to hang the hexagon netting, and with this at the time of my visit the whole wall was covered to exclude flies, wasps, &c. There was a narrow path near the base of the wall as usual, but the border seemed to have been fully cropped with various early vegetables, so that the trees had not the whole of the border to themselves; their success must therefore be attributed to the natural good quality of the soil and the care bestowed on them. Mr. Luckhurst has repeatedly explained his mode of treatment at the monthly meetings of gardeners held for mutual improvement at Maidstone. Its principal features are careful attention to the first appearance of insects, destroying them at once, adopting precautionary measures to prevent their attacks, and other attentions to the wants of the trees, especially to little matters that are often neglected, but which, if not looked after, often lead to the worst consequences.

When I described the soil as being well adapted for most trees, I ought also to have stated that the subsoil is the same; in fact, in the growth of trees of most kinds, I always think the subsoil is of more importance than the surface soil; but the latter is said to be so good that there is very little difference perceived at the depth of 3 feet, and for many feet below that the porous character of the understratum is favourable to the roots, being plentifully interspersed with stones, the value of which is too often underrated even when at the surface. In large portions of this garden I am told that the understratum had been broken up when the ground was worked as a quarry, hence the more free action of the roots; besides which, the absence of stagnant water and other impurities, renders it safe for the roots of trees to descend any reasonable depth without continuing growth so late in the autumn as to endanger the ripening of the wood. I imagine if we could trace the rootlets of many of the fine trees of the Peach and other fruits, we should find them interlacing the stone shatter.

The Moorpark Apricot here is liable to the same evil which befalls it at other places, for large limbs die off, but certainly not to the extent I have seen elsewhere, but the trees in general fruit well, and so do the finer kinds of Plums, while Morello Cherries are grown almost by the bushel against a north wall, and, when covered with hexagon netting, will hang a long time. The only tree I noticed as being short of a crop, was a fine specimen of Gansel's Bergamot Pear, covering every inch of a piece of wall 60 feet long by 12 high. This tree had but a thin crop upon it, while adjoining it *Bourré d'Aremberg* and *Duchesse d'Angoulême* were bearing heavily, thus showing that Gansel's cannot always be depended upon for a crop.

Some choice kinds of Apples and Pears were grown on espaliers near the garden walks, the border between the trees and the walk being cropped with Strawberries, and to keep the fruit of the latter clean the ground was covered with pebbles or broken stones, about the usual size of road metal. Mr. Luckhurst has a high opinion of *The Lady* and *Marguerite* Strawberries. The collection of Apples contains most of the leading

varieties. In an adjoining orchard were standard trees producing ten, twenty, or more bushels each; but high winds had done much damage, by blowing down large quantities of the best fruit. In taking a hasty glance at this orchard, a fine healthy Ribston Pippin Apple tree, of large size, was pointed out to me. I was much surprised at this, for it is rarely that we meet with this popular variety in good condition, the trees being usually in a more or less diseased state, with dead boughs and spotted fruit, but at this place it had all the freshness of other kinds.

Notwithstanding the extremely dry weather, there were some very good vegetables. Most of the Potatoes had been taken up and stored, and I was told the crop had been good for the season, and as the planting had been early, they were less affected by the dry weather than those planted later. A small French Cabbage was pointed out as being much esteemed at table; it had also the good quality of not being liable to run to seed, and might be planted very close together. On one of the wall borders I noticed a row of Tomatoes treated exactly like Peas, being trained to stakes, and bearing and ripening their fruit well. A small Cabbage Lettuce, of continental origin, was also said to possess the property of not running too early to seed in dry, hot weather, as so many of our Lettuces did last July.

It is seldom that one enters a garden where there is such an abundance, variety, and excellence of produce, as at The Mōto, and the greatest credit is due to Mr. Luckhurst and his sons, one of whom, I believe, is now associated with him in its management. I have no doubt that the fine Peach trees will be equally well cared for in future, and will remain for many years a living proof that the climate of this country has not deteriorated in all places so as to prevent this tree from thriving, and its fruit ripening, in the open air.—J. ROBSON.

SUBTROPICAL PLANTS AT BATTERSEA PARK.

The following are the heights attained this year by a few of the plants employed in the subtropical department, Battersea Park:—

<i>Ferdinandia emibens</i>	13 feet	<i>Cinnamomum</i>	9 feet
<i>Wigandia caracasana</i>	8 feet	<i>C. Van Houttei</i>	9 feet
<i>Polynia grandis</i>	6 feet	<i>Solanum laciniatum</i>	8 feet
<i>Canna peruviana</i>	11 feet	<i>Ricinus</i> , several varieties	13 feet
<i>C. Annaei</i>	12 feet	<i>Musa ensete</i>	15 feet

The stem of one plant of *Musa ensete* measured 4 feet 5 inches in circumference at the ground, and 2½ feet at 3 feet higher up.

REPORT ON THE BRISBANE BOTANIC GARDENS.

MR. WALTER HILL, Colonial Botanist and Director of the Brisbane Botanic Garden, Queensland, has made his annual report, dated March 28th, 1868. The following is an extract:—

"In the experimental department of the grounds, I would first refer to the cortical fibrous class of plants. Among the most important of these is the *Urtica niven*, or China Grass Cloth plant, which has in point of cultivation, been attended with far more success than was expected. The situation selected for the purpose was anything but the best; and for the purpose of testing its adaptability to a Queensland climate, no attention was paid to it beyond its original planting. Notwithstanding this, the tenacity and rapidity of its growth has been surprising, and the only thing left to deplore is the lack of mechanical appliances in the colony which would prepare the fibre as an article of commercial value. In connection with this subject, I would acknowledge the receipt of a report on 'The Cultivation and Preparation of the China Grass Plant,' which was accompanied by a circular emanating from the Home Secretary for the Colonies, and which was kindly forwarded to me by His Excellency the Acting Governor, 'for my information.' My experiments, however, with the plant, satisfy me that the Queensland climate is far better adapted for it than that of China, to which it is indigenous; for while in that country the plant has to be constantly watched and tended, watered, weeded, and protected from the cold, &c., here, as I have already shown, after planting the roots about the month of November, no further consideration is requisite to develop its perfect maturity. The other fibrous plants, which demand a passing notice in this report, are the Jute (*Corchorus capsularis*), and the Sun Hemp (*Oreolaria juncea*). These plants, also, are valuable in a commercial point of view, thrive luxuriantly, and mature most rapidly, and, like the Grass plant, require little care or attention. The cultivation of the Indigo plant (*Indigofera tinctoria*), has proved thoroughly satisfactory. A sample has been submitted for manufacture, and the result proves that this valuable article of merchandise will yield, both in quality and quantity, as well in Queensland as in the East Indies. If attention be paid to the proper season

for sowing it, like the fibrous plants, it requires but little care, and, like them, arrives rapidly at maturity. It is to be hoped that ere long the cultivation of Indigo will engage the attention of Queensland agriculturists, as the never-failing market which it commands, and the standard value which it maintains, will, with the other recommendations suggested, doubtless render it an important article of Queensland industry and wealth. A sample of the China Tea (*Thea Bohea*), has also been manufactured from plants grown in the gardens. Although it has not had time to season (three months, at least, being deemed necessary for this purpose), it has been pronounced a very fair article by judges who have tried a decoction of it, and that not many days after its manufacture. It thrives best on undulating lands, and if the situation selected be propitious, any further consideration for its development may be regarded as secondary. As far as my knowledge of the plant extends, an experience of eleven years in this colony, justifies me in pronouncing it as in every way adapted to the climate of Queensland. Samples of the berry from the Coffee plant (*Coffea arabica*), grown in the gardens, have been submitted to manufacture with most satisfactory results. The plant has proved itself to be easy of cultivation, and its treatment, in comparison with the Tea plant, only differs inasmuch as it requires a greater degree of shelter from the westerly winds. It may be ranked as one of Queensland's important and successful products.

"In my last report I had occasion to refer to three distinct species of the Cinchona plant, imported from Java, which I planted in a favourable situation. One species (*Cinchona calisaya*), is now flowering, which I interpret as further evidence that the climate and soil of Queensland are well adapted for its successful cultivation.

"The eight varieties of Sugar Cane, imported from Java at the same time as the Cinchonas, are thriving well, and in the rapidity of their growth seem to outvie nine other varieties, which have been imported from other countries, and which have been under cultivation in the gardens for some years past. I am unable to state confidently anything further in praise of the Java canes until such time as the usual manufacturing process shall determine the per-centage of their yield of saccharine matter.

"Among other plants introduced from Java last year, I may refer to the Vanilla (*Vanilla aromatica*), the Bitter Wood (*Quassia amara*), the Chocolate or Cocoa (*Theobroma cacao*), the Gum Elastic or Caoutchouc (*Siphonia elastica*), six varieties of Mangoes, and six varieties of the Plantain, all of which are giving indications of successful acclimatization. The latter are now in fruit, and if generally distributed in the colony will become popular as an article of food. Although I have been enabled to speak in flattering terms of the many different productions, there are still specimens of others in the gardens which, I have reason to believe, would flourish far better in lower latitudes—viz., the Mangostan (*Garcinia mangostana*), the Clove (*Caryophyllus aromaticus*), the Nutmeg (*Myristica moschata*), and the Bread Fruit (*Artocarpus incisa*).

"The following is an enumeration of such trees and shrubs as have flowered and fruited for the first time in the gardens—viz., *Cocos palmosa*, *Arecia lutescens*, *Tectonia grandis*, *Dillenia speciosa*, *Brownea coccinea*, *Cinchona calisaya*, *Siphonia elastica*, *Quercus spicata*, *Gardenia Stanleyana*, *Gardenia Rothmannia*, *Rhododendron jasminiflorum*, &c."

GOLD AND BRONZE PELARGONIUMS

"W. B. G." (page 242), is perfectly correct, that Mrs. Milford, &c., were in the market long before Beauty of Oulton, but it must be remembered that the former has but a very faint zone compared to the latter, and, correctly speaking, neither is now worth growing; for the improvement in this class of Pelargonium has been very rapid in the last two years, and it is difficult to say which is the best, as so much depends on the way they are grown. However, enough has been seen of all the varieties sent out up to May, 1868, to justify saying which has been the most effective throughout the late extremely hot and dry weather. "W. B. G." appears to have taken all his experience from Battersea Park, and from some cause, probably from over-watering when the sun was upon them, they have there looked worse as regards colour and refinement of their zones than any I have seen this year. Had "W. B. G." seen them at Chiswick, planted in some round beds, where one could examine them minutely, and draw back as far as one liked to see the effect at a distance, he would have been of a very different opinion.

As regards Beauty of Calderdale being better adapted for pots, a connoisseur friend of mine described it to be the most effective of the whole, and so far as regards the bright, bronze zone, there can be no doubt of it, and the habit is all that could be wished for in a bedder. Model is of dwarfier growth, and better fitted for outer lines. It is perfectly distinct, and I much question if there is another Bicolor, Sibyl and Criterion excepted, with a more regular and better defined zone than Model; and there was not much deficiency of yellow, although it was, perhaps, not quite so intense as in some of this year's

kinds. I have had Beauty of Ribblesdale and the two above mentioned almost green throughout last autumn and spring, and I had fully made up my mind that they had degenerated since I saw them in such fine condition in May, 1867, at South Kensington, but this was caused by the want of knowledge, and not having a proper mode of growing them.

"W. B. G." would almost lead one to suppose that Egyptian Queen is a very effective first-class variety as compared to others; but I think nearly all growers who have had this new variety during the present season are unanimous in their decision that it is not so good as others sent out this year. It certainly falls very short in regard to the following qualities—namely, substance of leaf, brightness of colour in both yellow and bronze, and it is rather more delicate, and of more moderate growth, than many varieties of its section. It is perfectly true that the Committee gave their highest award to Kentish Hero, and it was, no doubt, the most effective at the time of examination; but had they deferred their visit another fortnight or three weeks, I feel convinced that other kinds would have gained this honour.

Kentish Hero is a strong and rather coarse variety; its leaves are far from being of a good shape, curved, and very much vandyked. It is a good improvement on Perilla, and for large beds, one of the best. For ordinary bedding purposes I think there are several varieties that will prove far more useful and effective than Kentish Hero, particularly in ordinary seasons.—H. CANNELL, *Woolwich*.

INSIDE VINE BORDERS.

SOME time in the autumn of 1867 a controversy took place in your columns respecting this subject, and I think your correspondents were referred to the viney of T. N. Miller, Esq., of Bishop's Stortford, Herts.

This viney, 200 feet long and 30 feet wide, has only inside borders, the roots of the Vines being confined to them by brick walls with deep foundations. The borders, or rather border, for there is but one occupying the whole width of the house, has, I believe, an annual surface-dressing. The Vines have been planted six years, and are at this time in the finest possible health and vigour, loaded with fine bunches. This method of forming a Vine border seems to me very simple, doing away with the necessity of covering to keep off the heavy rains of autumn and winter, which outside borders require; besides which, the inside border partakes, to a certain extent, of the temperature of the house, instead of being chilled by the cold rains and frosts of winter, and thus roots and branches are in harmony.

An amateur, unknown to the annals of horticultural fame, has thus given a lesson to Grape-growers. I scarcely need add that Mr. Miller allows Mr. Ward, his gardener, to show his viney to all persons interested in Grape-growing.—VITIS.

EFFECTS OF THIS YEAR'S SUMMER IN OUR GARDENS.

EIGHTEEN HUNDRED AND SIXTY-EIGHT will be held in remembrance by many of the present generation, for the long-continued drought, and, at times, the almost unbearable heat. The want of water in many places has been most keenly felt, and in none more so than our own. For months we had none but that which had to be brought from a distance. Still we have cause for thankfulness; trying as the season has been, we have had a very good supply of most garden crops. This I attribute to deep cultivation.

The spring being early we had a good supply of Asparagus in April from the open ground; we lifted Potatoes, and gathered Peas on the 26th of May; from autumn-sown Cauliflowers we began to cut in the beginning of June, and we have had a regular supply up to the present time, and hope to continue it till the winter Broccoli is come in.

Considering the dryness of the season, and the little water we had at command, vegetables have done very well indeed. Onions and Carrots are rather small. Beet has done uncommonly well this season; Carter's St. Oystin has proved the best, it is a good crimson Beet. Parsnips are really good. Turnips have suffered much from mildew. Tomatoes against the walls have been remarkably fine, and the crop abundant. Early and late Broad Beans have been very fine. Beck's Dwarf Gem is a useful kind for early work. Scarlet Runners and Dwarf Kidney Beans have been very fine, and in a great

measure free from their worst foe, the red spider. The Early Six Weeks is a good kind for early out-door crops.

The Potato crop has been most abundant, and of the very best quality. We have had very little supertuberating in our garden. The varieties we grow are Myatt's Prolific, Haigh's or Lapstone Kidney, and the Fluke. We have tried the French Kidney and other kinds for three years, but with us they do not answer, therefore we have discarded them.

Celery is with us a partial failure, partly, I think, owing to the dry season. At the present time it has the appearance of being scorched; many of the leaves appear to have large blotches on them, but from what cause I am unable to say.

We have had to keep a vigilant watch for caterpillars, which have been unusually abundant this season; now that the frosts and autumn rains have set in they have in a great measure disappeared.

Cucumbers and Melons have done well this season. Ridge Cucumbers and Vegetable Marrows have been very abundant.

Fruit generally has been abundant, though with us the Strawberry crop proved a partial failure. Currants of all sorts were very plentiful and fine. Raspberries were abundant and remarkably fine. Of Gooseberries there was a heavy crop, but the bushes were severely attacked by caterpillars, which were picked off and destroyed; I find this the best remedy. Wall fruit has been very good. Apricots, especially, were early and of first-rate quality. Peaches and Nectarines were not quite so good. Owing to their not having the requisite supply of water they were in some instances rather small and not of first-rate flavour, this being in some measure also attributable to the red spider having become rather numerous. This insect has been remarkably prevalent during the present year in many places.

Figs have come to great perfection this season. Plum trees have produced a very fair crop of good quality, and the fruit has kept well considering the multitude of wasps and flies we have had. At the present time some of the later varieties are hanging on the trees without any protection. These may be kept for some time by taking them with their stalks carefully from the tree, tying them to a string, and hanging them in a cool, dry room. Coe's Golden Drop treated in this way, when half dry, is really first-rate. Ickworth Impératrice when thus treated answers well for tarts, and other late kinds are desirable as long as they can be kept. We had a splendid crop of Rivers's Early Favourite, and Early Prolific ripe here in the end of July. They are really first-rate early kinds; so, too, is Précoce de Tours.

Cherries have been abundant and good; but from want of protection the birds had the lion's share. The Morello and Coe's Late Carnation are still in good condition under the nets, and are doing good service along with Red Currants that have been covered up.

Pears on the walls have been fine this season. We have now in fine condition for the dessert Flemish Beauty, Seckle, and Marie Louise. In the orchard Pears have also been good. Apples have been most abundant; they ripened early, and are of good quality. Those which have been stored are keeping well at present.

The autumn showers have been a boon to us. The trees, having ripened their fruit and wood, are beginning to shed their leaves in abundance; the rain, frost, and winds bring them down rapidly. Root-pruning, planting, and any alterations that may be in contemplation should now be pushed forward. No time should now be lost by those who intend planting, the ground being in excellent order.—M. H., *Acklam Hall, Middlesbrough-on-Tees*.

FLOWER BEDS IN AUTUMN.

GOLD AND SILVER-EDGED *versus* TRICOLOR PELARGONIUMS.
BEET AS A ZEDDER.

THE very practical remarks of Mr. Robson under the above heading, in page 296, are well worth the consideration of all gardeners having much to do in the way of flower gardening; I therefore wish to make a few remarks on the subject.

In the first place I can fully endorse, as far as my own experience goes, Mr. Robson's opinion on the superior merits of the Gold and Silver-edged Pelargoniums over the Tricolor varieties for giving general effect, and particularly so when viewed, as he very rightly remarks, from a distance; indeed, I consider Golden Chain at any distance superior to Mrs. Pollock when required as a contrast to other colours. In my opinion

Golden Chain is still the best Golden-edged variety we have. The yellow is more pure and constant than in any other kind that I have yet grown or seen; and being a variety that lifts remarkably well in the autumn, and keeps well through the winter, its slow growth, for which it is condemned by many, is not so great a drawback to it after all, as the same plants can be used for three or four years in succession, and by striking some every year a stock of it may be always had of a good size. I generally put in a lot of cuttings of it between the older plants at bedding-out time; these help to fill up, and they form good young plants for lifting in the autumn.

My experience with Tricolor Pelargoniums fully agrees with what Mr. Robson says with respect to Mrs. Pollock losing much of its beauty under the influence of extreme sun heat. I have often heard it remarked, that Mrs. Pollock and other Tricolor varieties require exposure to plenty of strong sun to bring out their colours to the best advantage, but in my own experience I have invariably found the reverse to be the case. For instance, Mrs. Pollock was far superior in colour with us here last summer than it has been this year, until the beginning of September, when it began to improve, and has since been very fine. Possibly some persons may say that drought has more influence as regards want of colour in the leaf than the intense heat; but I can scarcely think so, as Mrs. Pollock with us this summer was abundantly supplied with water taken immediately from a lake, and, consequently, in the best condition to apply to plants, and the plants grew well. I am more inclined to attribute the cause of loss of colour to the fading, when exposed to a very hot sun, of the colouring matter which constitutes the zone in the leaf, but in this I may be wrong, and would like to have the opinion of others on the subject.

Luna with me this season has been very much better in colour since the beginning of this month (October), than at any previous time throughout the summer, excepting, perhaps, for a week or two after it was planted out.

Italia Unita, as a Silver-edged Tricolor Pelargonium, although beautiful as an individual plant, is not in my opinion nearly so effective for general effect and contrast with other things as the Silver-edged varieties. The best of the latter which I have yet grown is Miss Kingsbury, possessing an excellent habit and good robust constitution, and retaining its foliage well to the last. I consider the Tricolor varieties will prove very useful—that is, those of as good constitution as Mrs. Pollock, of which I fear many fall short—as being very effective late in the season, and good for wet summers when many flowering plants get much dashed and injured. Of course, they will be good in fine summers as well.

I will now comply with Mr. Robson's invitation respecting the merits of the Beet as a dark-foliaged plant for decorative purposes, and in doing so I cannot speak too favourably of it, so far, at least, as the variety I have grown has proved itself here this season. It has certainly been the plant of the season here in the way of dark foliage, no other plant in the flower garden having received so much special notice and praise, and it certainly, in my opinion, deserves all the praise it has received. It has a richness peculiarly its own, and not possessed, so far as I know, by any other plant used for the same purpose, and this it has retained throughout the season up to the present date (October 24th), being equally good in the hottest part of the summer, as it has been since, which is more than I can say of some other dark-foliaged plants used here this season. For instance, in the hottest part of the summer the leaves of the Coleus (which has done moderately well otherwise), became scorched and brown to a certain extent. Again, in the case of the Perilla, the caterpillars played sad havoc with it, quite disfiguring the greater part of it for a time. The few plants of Amaranthus which I grew did very well up to the beginning of this month, when, as it always has done with me, it began to fog-off. As far as this season goes, and it is the first I have grown it in the flower garden, I must certainly give the palm to the Beet, as being the best dark-foliaged plant I have grown, not the least of its advantages being, that it requires very little attention after being once put out, and does not appear to be likely to be attacked at any time by insects.

I believe the variety I have grown is a very superior and true strain. I obtained the seed from Messrs. Francis and Arthur Dickson & Sons, Chester, in the spring of this year under the name of, or rather labelled, "Dwarf Black-leaved Beet for flower-garden purposes," and certainly a better variety for the purpose I do not think could possibly be grown, and I shall certainly endeavour not to lose it.

Chrysanthemum Sensation has retained its foliage with me up to the present time, and I like it much, being very good for edgings when kept well stopped, which improves its colour.—JOHN H. MASON, *Prince's Park, Liverpool.*

POMOLOGICAL GLEANINGS.

FRUIT here (Gargrave) is very fine this year. A seven-year-old Easter Beurré Pear, on the Quince, trained upright, and 9 feet high, with five branches, bore thirty-six Pears. I weighed the entire crop; the weight was 18 lbs.; average weight half a pound each. Madame Treve, which you figured in the Journal, is a glorious fruit; here one fruit weighed 10 ozs., another 10½—as melting and vinous as a fine Peach, the best September Pear I have ever tasted. Skin fine, thin; no core, no grit. Then the tree is healthy, vigorous, and sets fruit buds in abundance.—C. M.

—FROM the garden of J. B. Houston, Esq., Orangefield, Belfast, we have received fruit of a RED CURRANT, from bushes growing in the open quarters. This variety ripens with the Ruby Castle and others, but retains its fruit and foliage until late in the season, in fact, until severe frost sets in. The foliage now (October 17th), is quite green, while Ruby Castle, growing beside it and under the same treatment, is ready for the winter pruning.

Bunches mostly short, resembling the Grape Currant, but very productive, bearing enormous crops. While in the young state the bushes grow very vigorously, and require lifting and replanting. Foliage thick and leathery, in shape something resembling the Mallow leaf.

During the autumn of 1867 nice fruit was gathered in the first and second weeks of December. The footstalks were as green and the berries as plump as if it had been August.

—AMONG the curiosities of pomological literature may be reckoned the following extracts from a French fruit-tree catalogue we have just received. Among Gooseberries we find "Bunker's rill," "Ewotoone," "Leaoche," which being interpreted mean Bunker's Hill, Two to One, and Peacock. We publish this as a warning to English nurserymen, to be careful how they print French names in their catalogues, which we observe are frequently as comically represented as the examples of Anglo-French we have given above.

—"I NEVER remember to have seen so great a resemblance between two varieties of fruit as in the STIRLING CASTLE and SMALL'S ADMIRABLE APPLES, for they are of the same dwarf habit—apparently of the Hawthornden race—and both prone to bear when the trees are in a very young state, often bearing profusely on trees not more than 2 feet in height, the second year after grafting, if on the English Paradise stock. On examining the trees and the fruit of both I have discovered some slight variations, which have induced me to think they are not (as I thought when looking at the young trees during the summer), the same variety under two names. The fruit of the Stirling Castle is of the same shape, colour, and size as Small's Admirable, but has its eye set in a much deeper basin. The young shoots of the tree are spotted with white like those of the Admirable, but they are much lighter in colour. Those of the latter are of a very dark brown; but the most distinctive character is in the leaves, those of the Stirling Castle being nearly round, while those of Small's Admirable are comparatively long and pointed."—T. R.

—THE EARLY NONPAREIL APPLE.—With respect to this Mr. Rivers writes, "Pray allow me to disclaim all right to have my name appended to this very old variety (see page 284). My history is as follows: Some sixty years since there were old trees of this sort growing here, said to have been planted by my great grandfather. They were decayed and full of cankered shoots. In a warm season they bore fine fruit, which I used to think most delicious. In those times it was designated the Early Nonpareil, and I know of no other kind deserving the name. Many years afterwards this name was applied to Hicks' Fancy, in my opinion a very inferior sort.

"I venture to give the following description of the Early Nonpareil or Haute Bonne (not 'Haute Bonté' as I misquoted), from the folio edition of dear old Miller's Dictionary. What capital English is Lis! 'The Nonpareil is a fruit pretty generally known in England, though there is another Apple which is frequently sold in the markets for it, which is what the French call Haute bonne. This is a larger, fairer fruit than the Nonpareil, more inclining to yellow; the russet colour

brighter, and it is earlier ripe and sooner gone. This is not so flat as the true Nonpareil, nor is the juice so sharp, though it is a good Apple in its season."—THOMAS RIVERS."

— **BEURÉ DU CERCLE PEAR.**—This is a new Pear of much promise. It is the first season of its bearing fruit in this country to our knowledge. A little pyramidal tree in the Royal Horticultural Society's garden, Chiswick, has this season produced half a dozen large and beautiful fruit, which have proved of really excellent quality. The fruit is large, obovate, tapering irregularly towards the stalk; surface irregular, bulging out in places. Skin smooth, of a beautiful pea-green colour, with a slight patch of russet round the stalk. Eye small, open, set in a very shallow angular basin, almost level with the surface. Stalk long and slender, inserted a little on one side without depression. Flesh greenish white, delicate, buttery, and melting, very solid, with scarcely any core. Flavour rich and pleasant.

This is a Pear which we anticipate will take a high rank. In appearance it is somewhat like a Glou Morceau, but is distinguished by the very long slender stalk and the deep green skin. The flesh resembles that of the Marie Louise and Glou Morceau. Ripe in October. Grafts of this variety were received by the Society in 1860 from the Société Impériale et Centrale d'Horticulture du Département de la Seine Inférieure.

— At the last meeting of the Fruit Committee of the Royal Horticultural Society, the six splendid specimens of **BEURÉ CLAIRGAT PEAR**, exhibited by Mr. Cox, of Redleaf, were, on being weighed, found to be 5 lbs. 14½ ozs.

NOTES AND GLEANINGS.

ADULTERATION OF SEEDS.—On Friday last, some members of the seed trade met the Council of the Royal Horticultural Society to consult on this subject, in accordance with the recommendation of the Sub-Committee, whose report was published in our number of the 15th inst.

— We have a fair sample of Walnut-leaved Kidney Potatoes, being part of the second crop this year. A planting was made on April 14th, the crop from which was taken up on the 8th of July. Some of this crop were planted again on the 10th of July, and the crop from them, of which we have the sample, was taken up on the 20th inst. We received the sample from Mr. L. R. Pocock, gardener to N. M. Forbes, Esq., Elmwood, Bickley, Kent.

WORK FOR THE WEEK.

KITCHEN GARDEN.

Digging and trenching ground, and wheeling manure should be reserved for frosty weather. On light soils all fruit trees ought to be planted during this month, but on heavy clay soils some persons prefer the middle of February. *Cauliflowers*, hand-glasses are awkward when in one piece, and when placed over Cauliflower plants thin boards should be put down between the rows to walk on when giving air and stirring the soil. *Endive* and *Lettuce* in the open ground and in frames require great attention this month, lest they damp off or be attacked by slugs or snails. *Peas*, where there is no convenience for forcing Peas in February, a few rows are generally sown early this month, and chopped Gorse tops are put into the rows over the Peas to keep away mice, but nine times out of ten those sown in autumn are lost, or nearly so, by being sown too early. Except in the case of very sandy soils, and in high situations, the last week in November is time enough to sow. *Asparagus*, *Sea-kale*, and *Rhubarb*, preparations must now be made for forcing these where they are wanted early. For the first nothing is better than a late Melon bed that still retains a moderate heat, or a slight hotbed may be made so as to moderate the heat at pleasure if it should prove too strong. Place the plants as closely as possible, and so near the glass as just to allow the shoots to grow the requisite height, and then they may be had green or blanched at pleasure, unless the weather should be very severe. The best method to adopt for the *Sea-kale* and *Rhubarb* is to form a small hotbed in any convenient place, take up a number of roots, place them on it, with a little soil of any sort amongst them, and defend them from the weather and light by any old boards that can be obtained. Where a Mushroom house is at work a better place could not be found.

FRUIT GARDEN.

Remove all green laterals from Peaches and Apricots that

the growth of the trees may be checked, and with a new birch-broom gently switch off the matured leaves, taking care not to injure the buds, repeating the operation at short intervals so that the young wood may be ripened by exposure. To afford a still greater amount of this, cut out any small twigs that will not be wanted, and loosen from the wall, as soon as convenient, those shoots intended for bearing next season. When, unfortunately, the leaves are still green and adhere, no time should be lost in going over the trees and cutting all the stronger leaves. This will tend to check luxuriance and hasten the maturity of the buds without rendering the shoots either shrivelled or receptacles of unelaborated sap liable to break out in gum or canker, which in such cases is often the result when recourse is had either to indiscriminate root-cutting or a wholesale deprivation of leaves. Constant attention should be paid to the fruit-room until all the autumn fruit is over. Short memoranda should be made of the qualities of the different sorts as they become fit for table or kitchen use. After a few years these may be compared, and will be found very useful.

FLOWER GARDEN.

The business of this department is now in a great measure confined to the clearing-up of leaves, worm-casts, and decaying vegetable matter, and making the lawns, &c., as tidy as the season will admit of. If the bulbs are planted—and if they are not, no time should be lost in putting them into the ground—those beds which are unoccupied may receive their winter-digging, or, where necessary, winter-trenching, taking care if the soil is strong to expose it as much as possible to the action of the atmosphere. While, however, you dig the beds, avoid touching the shrubbery borders, for though they look much better after being dug, plants do not grow any faster from being annually root-pruned, and such is the effect of an annual digging. Worms are now very troublesome, especially in weather when it is difficult to clear their casts away, but their ranks may be materially thinned by watering the ground with fresh lime water or with water containing corrosive sublimate, though in the latter case they are merely driven out of the ground and require to be gathered-up by hand and afterwards destroyed. Corrosive sublimate is very quickly brought into a liquid state by mixing it with spirits of salt. If the Auriculas are in their winter quarters they should be protected from damp, and especially from rain finding its way in by the glass of the frame and dripping into their hearts. In order to prevent this the laps of the glass ought to be puttied. If pots become saturated with rain and are neglected but for a few days, the destruction of the plant is almost inevitable. In many parts of the country Dahlias have been cut off by the late frosts; where such is the case they should be taken up, otherwise they will start again at the crown. With strong metallic wire attach to them zinc labels which have been numbered, and they may be hung up for a few days to dry in any airy shed preparatory to cutting off the stems, and storing the tubers for the winter.

GREENHOUSE AND CONSERVATORY.

Ipomoea tyrianthina and *Tacsonia pinnatistipula* are two beautiful climbers for the conservatory, requiring exactly the same treatment, but they are rather difficult to manage in modern structures, as they are impatient of confinement, and do not like bright sunshine. The best way to treat them is to plant them in the front border, and have the tops taken out to the open air through the summer, but this style is inadmissible when a conservatory forms part of an architectural assemblage; in that case they should be planted near the doors or sources of ventilation, or against the back wall. In either case they should be trained low, and kept particularly shaded, and never allowed to reach the top of the house. They are good subjects for old-fashioned houses, where they may ramble at ease. Because *Chrysanthemum* are thirsty plants, and apt to draw in confinement while they are growing, some people think they must have large doses of water, and a free circulation of air while they are in bloom. Try them, however, in a close, cool, dry house, and you will find that half the usual quantity of water is enough for them. They will continue in bloom longer, and do not become drawn.

STOVE.

By the end of October stove plants, not winter growers, should be thoroughly ripe, and will require less heat than they have had for the last six weeks. A temperature of 60° is now high enough at night, and that should be about the standard heat for the next six weeks, after that 55° will be high enough till the return of fine weather early in spring. If the air in the house could be kept as pure as that in the conservatory through

the winter, the plants would require very little ventilation when at rest; but with strong fires this cannot be done, and the air must be changed as often as the weather will permit. One of the most graceful winter-flowering stove plants is the *Acacia kermesina*; it is a plant of the easiest culture, and flowers on the top of the shoots, and like all plants with this habit, it should be often stopped when young, to induce the formation of a quantity of side shoots, as the more shoots the more flower-heads. Grafted standard high on *Acacia affinis*, its near relative, it would form a splendid object in a short time.—W. KEANE.

DOINGS OF THE LAST WEEK.

Effects of the Frost.—Last week we expressed a hope that our first frost would not come on a Sunday evening, but it did come, nevertheless, rather sharp on that evening (October 18th), and as the weather looked as if we should have more of it, we lifted some of the most tender plants, and placed them under protection on Monday, and though the leaves of tender *Pelargoniums* were rather hard, they were not injured when thawed in the shade. For a particular purpose we were anxious not to dismantle our beds, and, therefore, we covered up some of the most tender plants on Monday night, but the sharper frost of Tuesday morning shewed us we had better at once make safe what we wished to preserve, and we took up a considerable number of *Pelargoniums*, &c., placing them in sheds or sheltered places, with a little loose litter thrown over them until we should be able to attend to them. We never recollect having such a severe frost as on Tuesday morning, so early, for many years. The surface of the ground was well crusted, and the leaves of unprotected *Pelargoniums* were as hard as pasteboard. Celery has been destroyed, and *Perilla* considerably blackened, and so have Dahlias and *Heliotropes*, but *Verbenas*, *Calceolarias*, *Salvias*, and the stronger-growing kinds of *Scarlet Pelargoniums*, are still green, and in many cases opening blooms after the drenching rains of the 23rd and the 24th. This is, no doubt, partly owing to the heat contained in the ground, and partly to the elevated position of the flower garden; and to this latter circumstance we would wish to draw attention for a moment, as it might be worth while for neighbours to compare notes in this respect.

We are all aware of the fact, that as a general rule the higher we go into the atmosphere, the greater is the cold we experience, until we reach the limits where snow and ice hold their perpetual reign. Within certain limits there are exceptions to this rule. Gardens in elevated positions are often untouched by the autumn and spring frosts, which cut up vegetation so much in the valleys. We have met with many instances in which even the bottom branches of rather tender trees have been seemingly burnt up by a dry frosty air, whilst the upper branches stood the test uninjured. From various accounts that reach us, the fact is ascertained, that gardens in valleys have suffered more, and earlier than we have done, and for this difference there must be a cause. We presume that the free radiation of heat from the earth would be very much the same from an extended elevated plateau as from a similar extended valley, though there might be a difference at the point where the eminence shelved down into the valley.

We have several times adverted to the simple fact that, as every body must be colder than the air around it before dew can be deposited on that body, so the deposition of dew and of hoar frost will furnish a test as to the cold produced by free radiation. We have no reason to conclude but that radiation of heat proceeds as freely from the higher ground as from that in the valley, and yet frost will be injurious in the valley, and the high ground will escape. Several times during this dry summer when the short lawn, so favourable for the deposition of dew in a quiet clear night, has been as dry as possible in the morning, so that even a satin slipper could not be damped, we have found dew on longer grass in a valley at a level of 150 feet lower. The only explanation that we can give for this singular but frequent occurrence is, that there is a constant tendency to an equilibrium of heat in the atmosphere, at least for certain heights; and thus, whilst the air on the lower ground becomes colder and colder, because the heavier and colder strata sink to the ground at once and can go no farther, the heat given off by radiation on the higher ground and higher positions, as the top of a tree, is for a time counterbalanced by the cold air finding a lower level and the warmer air rising to take its place. The matter is well worthy of consideration, as being of much importance as to the position of a garden; and if

these reasons be near the mark, they will show that slightly sloping banks will be less exposed to sudden frosts than the deep level valley, as for a time there will be an interchange of strata of air differing in density and temperature.

Wintering Old Pelargoniums.—Among the matters attended to in the week, which were chiefly a repetition of those alluded to in recent notices, and especially in the wet days, many of the *Pelargoniums* were taken up from the beds, as we always like to save some of them for different purposes, and these we treated in three different ways.

First, as respects some variegated kinds which we wish to keep and get cuttings from in spring. These we deprived of a few of their largest leaves, and when the roots were very straggling cut them in to 6 inches or so in length, and then we potted singly in small pots (10's), and set them in a slight bottom heat in frames, admitting air all night, that most of the leaves left may remain uninjured.

In a second case we took up some good-sized plants which we wish to keep for centres of raised beds or pyramids next season. We find that these are scarcely injured by the frost. As height is an object, we retain them almost at their full height, but to save room we take off all leaves larger than a sixpence, cut the roots if necessary, and place in the smallest pots that we can get them in, and put them under glass. Generally these make fine plants in spring. They would make fresh roots sooner if they, too, could have a little bottom heat, but that we could not give them, and to save room we wish them to grow very little during the winter.

The third is the most numerous lot, and the plants in this we merely wish to keep. We prune in the heads closely, leaving only a bud or two at the base of each branch. We prune in the roots to about 4 inches in length, and then we pack these roots closely in boxes—say thirty or forty of the close-cut deer-antler-like plants in a wooden box 3 feet long by 9 inches wide. If the soil is somewhat moist, they will need little watering, just a little to settle the earth about the roots. To prevent damping we dip the cut heads in a pot of quicklime. As not a single leaf is left on these cut-in plants, packed as closely as a wood faggot, they will keep anywhere in winter, where they will be secure from frost and damp, and will need but little light until they begin to break their buds, which they seldom do with us until March. These plants first treated with light then, and soon afterwards given more room, so that each plant may grow freely, will make a good show in the flower garden. This plan, or some similar one, is the best to adopt by those who grow *Scarlet Pelargoniums*, and have no greenhouse or glass pit to keep them in. Such skeletons need little care in winter. All young plants raised from cuttings must have light, as well as be kept from frost.—L. F.

COVENT GARDEN MARKET.—OCTOBER 28.

THE supply of fruit and vegetables is ample, with little variation in prices. The Potato market is firm for good sound descriptions.

TRADE CATALOGUES RECEIVED.

John Cranston, King's Acre, near Hereford.—*Catalogue of Roses.—Catalogue of Transplanted Forest Trees, Conifers, Evergreens, Fruit Trees, &c.*

TO CORRESPONDENTS.

*. We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

CLIFTON HORTICULTURAL SHOW (C. S.).—We cannot give a decided opinion on a case of which we have not the particulars; but we may say generally that a judge having awarded a prize to an exhibitor, gives that exhibitor no unalterable title to the prize, and it may be withheld if it be shown to the satisfaction of the Committee that the exhibitor was disqualified.

GROUND VINERY (W. A.).—The Vines require pruning, &c., just the same as when grown in a greenhouse. You will find full directions, drawings, &c., in "The Vine Manual," which you can have free by post from our office if you enclose thirty-two postage stamps with your direction.

FRUIT TREES FOR WALLS (P. K.).—We should plant Morello Cherries against the north aspect, and Marie Louise and Winter Nells Pears against the south aspect.

CUCUMBERS—PINE APPLES (J. B., Jersey).—Either Telegraph or Lion House Improved would suit you for Cucumbers. Any London seedsmen who advertise in this Journal could supply the seed. You can have "The Pine-Apple Manual," free by post from our office if you enclose thirty-two postage stamps with your address. You can also have "In-door Gardening for the Many," if you enclose twenty postage stamps. It gives directions for Cucumber culture throughout the year.

GLAZED CYLINDER VINERIES (Amateur).—Mr. Rivers's hexagonal vinery stands on a hill exposed to west and south-west winds. During a violent storm last winter it gave way 3 or 4 inches without breaking the glass. It has since then been made firm by driving spars into the ground on the opposite side to that exposed to the west. The open top seems very beneficial, as no watering or syringing is required, and Grapes ripen well. It should be covered with a mat in the month of May to exclude the spring frosts. The curled ends should be cut off, and manure 1 to 1½ inch in depth spread on the surface over the roots of the trees, in a circle from 3 to 4 feet in diameter, and allowed to remain there till March, when the surface may be stirred 2 inches in depth with the four-pronged steel forks used in gardens.

SALWAY PEACH (P. S.).—Eleven inches in circumference is large, and 1½ ozs. in weight is heavy, for a Salway Peach.

PRESERVING MEDLARS (J. C., Muckross).—Spread them singly on sand, open side downwards, first dipping the stalk end in strong brine to check mouldiness.

SELECT HYBRID PERPETUAL ROSES (Idem).—André Leroy, Alfred de Rougemont, Anna de Diesbach, Baronne Pelletan de Kinkelin, Beauty of Waltham, Caroline de Sansal, Charles Lefebvre, Comte de Nanteuil, Duc de Cazes, Duc de Rohan, François Lacharme, Gêant des Batailles, General Jacqueminot, Gloire de Santenay, John Hopper, Duchesse de Morny, Le Rhone, Leopold I., Lord Macaulay, Louise Magnan, Madame Boutin, Madame Victor, Maréchal Vaillant, Paul Desgrand, Pierre Notting, Prince Camille de Rohan, Prince Léon, Sénateur Vaisse, Vainqueur de Goliath, Virginal, and William Griffiths.

ROSE CULTURE (Q. Q.).—"If the Briers which have been budded push at this late season, take them up carefully, shake the roots out, and replant them. Except for this cause, it is best not to remove them. Do not break off the fibrous network. Orange fungus was evidently the cause of failure. There is no preventive nor cure except a pair of scissors patiently applied. Cut it out as early as it appears. It affects the under sides of the leaves. I never knew it begin earlier or more plentifully than this spring. My Rose-tree foliage is as good now as in May. Fungi of all kinds spread rapidly, destroy the action of the leaves, and produce ill-health. A practised eye will detect fungus at once by the discoloration of the upper side. It forms on the under side, then bursts, and forms 'Fenian centres,' till it spreads over a whole garden. Kill aphides now, and also early in spring. You will find them at both these seasons on the trees against the south wall. I have hardly had an aphid about my place this season. Of the varieties you possess, Madame Victor Verdier is first-rate. The following are, in my opinion, of proved Roses the best crimson:—Charles Lefebvre, Alfred Colomb, Sénateur Vaisse, Madame Victor Verdier, Pierre Notting, Duchesse de Caylus, and Maurice Bernardin. I think very highly of Antoine Ducher and Lady Suffield. I think you would be right to buy Princess Mary of Cambridge, Baronne de Maynard (love), Marie Baumann, which bears a high character; Antoine Ducher; Annie Wood, shows an eye; Francis Trevey, not yet proved here; Charles Verdier, first-rate; Black Prince, and Madame Margottin. Comtesse Jancourt is only just come. Charles Margottin is thin-petalled, but distinct. Comte Serpigny I do not know. As regards stirring the surface in summer lightly over the space occupied by the roots, it cannot be done too often. It lets in the night dews, which are in proportion to the solar heat,

moreover, less water will suffice. When ground is hard and baked, watering will only cool the surface without reaching all the extremities of the roots. Roses on the Manetti stock will do well in a north-east aspect if well looked after. Of the thirteen Roses named, I should not think highly of La Reine, François Lacharme (which requires high cultivation), Duchesse de Cambaceres, Duchesse de Caylus, Madame Julie Daran, Michel Bonnet, Madame Charles Wood (delicate), and Mademoiselle Gustave Bonnet. King's Acre is worthless, being a bad opener; Gloire de Santenay is a bad grower; Madame Boll is a good grower but somewhat tender; Madame Moreau is not tender, but is not a very good grower, yet occasionally very fine and distinct. Instead of La Reine you should buy La Ville de St. Denis, Gloire de Vitry, on its own roots, and the new Rose Madame Alice Dureau, probably the best of its year. It has been the best novelty here. I think well of Madame Rolland (not the same as Madame Roland), it will bloom again in a few days. It is a good grower. La France is distinct and handsome, a good grower, and a very quick bloomer, but I should think it would soil in a wet summer. It is a pretty Rose for glass. Its petals are reflexed at the edges, which is not a virtue.—W. F. RADCLIFFE."

PEGGING-DOWN ROSES (J. Reader).—"Roses for pegging-down must not be very stiff in their wood. At any rate great care must be observed in bending the shoots. The long shoots need not be cut out every year, only when they want renewal. The young shoots should be cut back a little to a good eye in sound wood. I believe the following are good and suitable Roses:—Hybrid Perpetuals—Anna Alexieff, Comte de Nanteuil, Baronne Prevost, Duc de Cazes, Empereur de Maroc, Elizabeth Vigneron, General Jacqueminot, Jules Margottin, Lady Suffield, La Ville de St. Denis, Baronne de Maynard, Madame Alfred de Rougemont, Madame Knorr, Maréchal Vaillant, Marguerite de St. Amand, Maurice Bernardin, Mrs. W. Paul, Pierre Notting, Prince Camille de Rohan, Souvenir de Dr. Jamain, and Souvenir de Comte Cavour. China—Mrs. Bosanquet. Bourbon—Acidalie. Tea—Sombreuil, Devonianis and Rubens. All the above are good on the Manetti stock.—W. F. RADCLIFFE."

AQUATICS FOR STOVE (S. P.).—Nymphaea carulea, N. Devoniana, Papyrus antiquorum, and Pistia stratiotes.

FLOWERING GLOXINIAS IN JUNE (Idem).—To have them in flower in June they should be started at the beginning of February. They should now be dried off and put to rest without loss of time, as upon their having a good rest depends a vigorous and healthy growth. Do not keep them too dry as that is apt to cause the roots to become farinaceous, and they rot when water is given. Setting the pots on a damp floor will afford enough of moisture.

POTTING CYCLAMENS (Idem).—In potting the corms of Cyclamen persicum they should be entirely covered with soil. The old plau of leaving half, or more than half, of them out of the soil is exploded.

CULTURE OF CLEODENDRON THOMSONI AND BALFOURII (Idem).—They are both stove climbing plants, and require a stove temperature. At this season water should be sparingly given, and by full exposure to light secure the ripening of the wood. In winter give no more water than enough to keep the wood plump. In February perform whatever pruning may be required, thinning out the old wood and shortening the long shoots, but leaving enough of the young shoots of last year, and when they begin to push encourage their growth with moisture and an increase of temperature. When the plants have shoots a few inches long repot, removing all the old soil as far as it can be done without injury to the roots, and use a compost of two-thirds fibrous loam from turf, and one-third sandy peat, with a free admixture of sand. Good drainage must be given. If convenient plunge in a bathed, taking care not to make the soil very wet but only moist, shading from bright sun, and keeping the atmosphere moist. When the plants have become again established encourage them with plenty of heat and moisture, affording a light situation, and regulate the shoots, training them thinly rather than very closely together.

INTERMEDIATE STOCKS (N. B.).—Your plants raised from seed sown early in spring ought to have flowered this autumn. If they withstand the winter they will bloom finely next spring. There are two sorts of Intermediate Stocks. One, called "Earliest-flowering Autumnal Intermediate," if sown in spring will flower in August and until destroyed by frost; and the other, "Intermediate or Autumnal-flowering," should be sown in July, potted-off, and wintered in a cold frame, and it will flower early in the following season and continue a long time in beauty, being on that account very valuable. For blooming at the same time as the bedding-out plants, the Ten-week Stocks are the most suitable.—G. A.

PROPAGATING ECHEVERIA METALLICA (E. Phillips).—It may be propagated by eyes, or a leaf taken off with a kind of heel as you describe. These, inserted in sandy soil in spring, and plunged in a bathed, will soon root if covered with a glass and kept moist and shaded. No doubt the best of all modes of propagation is by seed, but this is not very plentiful; therefore, we should prefer propagation by eyes, or division of the plant. The latter is a safe mode of increase, but can only be practised with large plants. You may grow it well in a compost of equal parts of turfy light loam and sandy peat, and a third part of charcoal in pieces from the size of a pea up to that of a hazel nut, with pieces of grit or sandstone of like size (or crocks will do), and silver sand, the whole well mixed. Let the drainage be good. Manure is of no advantage, though a little old dry cow dung will give increased vigour.

SELECT FRUIT TREES FOR WALLS (J. B.).—The south aspect of your north wall will be suitable for Apricots, Peaches, and Nectarines. Apricots: Kaisha, Heuskerk, and Moorpark; if you wish for an early sort add Orange, and for preserving Shipley's Early. Peaches: Early York, Royal George, Sulkampstead, Grosse Mignonne, Bellegrace, Chancellor, Barrington, Late Admirable, and Stirling Castle. Nectarines: Rivers's Orange, Elruge, Hardwicke, Violette Hative, and Pitmaston Orange. The north aspect will only be useful for Cherries of the Morello tribe, of which Belle de Charnoux, Belle Magnifique, Morello, and St. Margaret are the best. Your other low north aspect—i.e., of the south wall, will be suitable, because low, for Red and White Currants and Gooseberries, which may be had late by netting them. You will have two west and two east aspects. One-half of one of the east aspects we would devote to Cherries: Belle d'Orleans, Werder's Early Black, Bowyer's Early Heart, Eliek Tartarian, May Duke, Elton, Royal Duke, Florence, Lizarrean Napoleon, and Late Duke; and the other half to Plums: July Green Gage, Angelina Burdett, Early Orleans, Early Prolific, Victoria, and White Magnum Bonum. On the other east aspect have Pears and Apples. Apples: Adams's Pearmain, Eadlow Pippin, Calville Blanche,

Cellini, Newtown Pippin, Northern Spy, Orange Pippin, and Mannington's Pearmain. *Pears*: Citron des Carmes, Comte de Lumy, Albertine, Duchesse d'Angoulême, Williams's Bon Chrétien, Thompson's, Bergamotte d'Esperen, and Josephine de Malines. One-half of one west aspect—*Plums*: Green Gage, Kirke's, Jefferson, Coc's Golden Drop, Guthrie's Late Green, Coc's Late Red, and Reine Claude de Bayx. The other half, and the whole of the other west aspect may be covered with *Pears*: Beurré Diel, Beurré de Rance, Brown Beurré, Beurre Bosc, Gansel's Bergamotte, Crassane, Knight's Monarch, Marie Louise, Forelle, Flemish Beauty, Glon Morceau, Passe Colmar, Winter Nelis, British Queen, Van Mons Léon Leclerc, and Ne Plus Meuris. If we have named too many you may omit some of the kinds that come in nearly together, and where too few are given you may have duplicates of those which best meet your requirements. As your walls have buttresses at every 18 feet, we would make that the distance between the trees. The requirements of the family must be taken into consideration with respect to the number of trees of the different sorts. The trees against the walls should have borders of a width equal to the height of the wall, and there should be a walk in front of the border. On the opposite side of the walk to that on which the wall is situated, we would have a border 6 feet wide, and along the centre have a row of pyramid Apple trees on the Paradise stock, Pear trees on the Quince, and Cherry trees on the Mahaleb. The trees can be kept very compact and so as not to shade more than the border. The centre walk is to have borders on each side for herbaceous plants, with espaliers at the back. The pyramids may be planted 6 feet apart, or 9 feet apart with a Gooseberry bush between each, and for the first three years you may have a row of Strawberries on both sides of the borders at 15 inches from the edge.

CULTURE OF HOYA CARNOSA (Subscriber).—This plant is very accommodating. It will succeed in a stove, vinery, or greenhouse, but best in a warm greenhouse or cool stove. From this time until April the plant should be kept dry at the roots, receiving no water except when necessary to keep the leaves from flagging, which they must not be allowed to do. The best time to repot is when the plant begins to grow. Drain the pot well one-third its depth, and employ a compost of sandy loam from turf cut about 1 inch thick, two-thirds, and one-third equal parts of fibrous peat, pieces of charcoal, and grit or crocks from the size of a pea up to that of a hazel nut, with a free admixture of silver sand. Water sparingly for a time, but maintain a moist atmosphere, and when the plant is growing freely give liberal supplies of water, but avoid saturating the soil. A light and airy situation is necessary. You may take off a shoot in spring, cut it below a joint, trim off two or three of the lowest leaves, and insert it in a pot well drained and filled with open sandy soil. It will root in a few weeks if kept moist and in a gentle heat.

PROPAGATING THE ICE PLANT (Idem).—It is an annual and not desirably continued by cuttings. It is best raised from seed, for seedlings grow the best and with one-half the trouble—indeed, we are not aware that the plant can be perpetuated by cuttings beyond a year.

PROPAGATING ACCURAS BY CUTTINGS (L. S.).—The best time to put in Aucuba cuttings is as soon as the growth is complete, and the wood has become firm. They should be inserted in light sandy soil in a cold frame, and the soil made firm about them. A gentle watering should be given, and the lights kept on during the day and off at night, but in dull weather they may remain off day and night. Let the cuttings have the benefit of slight showers, but protect them from heavy drenching rains. Shade from bright sun should also be afforded. When cold frosty weather sets in the lights will be useful for protection, and in addition a covering of mats should be given in very severe periods. The lights must be tilted, so as to let the cuttings have air, and the latter should be fully exposed in mild periods. The cuttings may be struck out of doors in a sheltered shady situation, but they will be longer in taking root, and their growth will be slow. From the end of August to October the shoots will be in a good state for making cuttings, but they may be put in up to the middle of November, and in that case many will not root until the following autumn.

CAMELLIA BUDS DROPPING (Idem).—The cause of the buds dropping is a deficient supply of sap, arising from defective root action. This may be occasioned by unsuitable soil, or the soil being kept too wet, so that the roots perish after active growth ceases. A deficient supply of moisture, both in the atmosphere and at the roots, will also cause the buds to fall. The moss over the pots herds would not injure the roots, nor cause the buds to fall. The plants are unhealthy. The buds generally fall from plants which make weak stunted growth, and have small, thin, pale-coloured leaves.

SELECT ZONAL PELARGONIUMS (Idem).—Chieftain, scarlet; Lord Derby, scarlet, very bright; Clipper, scarlet; Sir Fitzroy Kelly, scarlet; Princess Dagmar, rose, upper petals half white; Queen of Roses, rose; Prince of Wales, salmon; Scrapp, orange salmon; Madame Day, salmon and orange, shaded pale flesh at the edges, centre white; Duchess of Sutherland, rosy purple; Constant Nivelet, bright carmine; and White Perfection. If you wish for double-flowering kinds, Gloire de Nancy, cerise crimson, and Madame Lemoine, rose.

PROPAGATING STACHYS LANATA AND DACTYLIS GLOMERATA BY DIVISION (F. J.).—The most suitable time to divide these plants is in the end of March or beginning of April, or when they are beginning to grow. *Stachys lanata*, however, is best raised from cuttings put in in August in a shady situation, moving them to their final quarters in spring with a half of earth to each. *Dactylis glomerata*, we presume, is the variegated kind, and that will do well divided and planted in May, care being taken to water freely in dry weather.

PLANTING ROSES (Idem).—The holes should be 2 feet wide, and 18 inches or 2 feet deep, and should be filled with good rich soil, adding about one-fourth of cow dung or rotten manure. Good garden soil will answer.

TEMPERATURE FOR BEDDING PLANTS (Idem).—You need not light a fire until the temperature fall to 40°, and that temperature from fire heat should not be exceeded. A gentle fire, however, in dull periods, to cause a circulation of air and to dry up damp, will be advantageous, air being admitted.

POTTING ZONAL PELARGONIUMS (Idem).—Old plants taken up now and potted will be better for early blooming than cuttings of this autumn, but they are not so free or fine in foliage, though free-blooming.

PLACING PELARGONIUMS IN SMALLER POTS (Idem).—The advantages of disrooting and placing in smaller pots are, that the plants form fresh

fibres, and can be supplied with fresh food in less compass than were they left in the old pots and shifted into larger ones; but the chief object of the proceeding is to keep them in vigorous health and good bloom without increasing the size of pot. By disrooting, the plants are put into smaller pots than those in which they have bloomed, and are ultimately replaced in the old size of pot for again flowering. It is a great saving of space, and a good mode of cultivation.

POINSETTIA PULCHERRIMA LOSING ITS LEAVES (A Young Gardener).—Your plant may have cast its leaves from their being infested with insects, or from a deficiency of moisture at the root. Without a specimen we cannot advise, but we see nothing in your treatment likely to cause the leaves to fall off.

BOOKS (Idem).—The "Garden Manual," Keane's "In-door Gardening," and "Cottage Gardeners' Dictionary," will suit you. They can all be had from our office, free by post, the first and second for 1s. 8d. each, and the third for 7s. 2d.

PREVENTING CLUB IN CABBAGEWORKS (C. R.).—Common salt, at the rate of 1 ton per acre, which should be applied to the surface and raked in when the ground is being prepared for the crop, is in most cases a preventive of the club in Turnips and Cabbages. Two cwt. nitrate soda will also be found a useful application. Your ground being full of insects, we would give a dressing of lime in March at the rate of one hundred bushels per acre, and on putting in every crop a dressing of 2 cwt. of nitrate of soda per acre, with enough soot to make the surface quite black, pointing in these applications with a fork. With the view of preventing club in all the Cabbage tribe, the roots and stems, previous to planting, may be dipped in soot, brought to the consistency of paint with water, adding to every gallon 1 lb. of saltpetre. The seed beds ought to be frequently examined, and plants exhibiting the symptoms of club should be drawn, the excrescence opened, and the maggot destroyed; then plant them in nursery beds by themselves. The plants will be known by their lagging behind the others and flagging under sun.

PEACH TREES LOSING THEIR LEAVES AND FRUIT (A Reader).—Planting Apple trees, so as to shade the Peach trees, would be wrong. They cannot have too much sun, and the leaves and fruit did not fall owing to want of shade, but want of moisture. Keep the trees syringed and well supplied with water at the roots, and after the fruit has set give a good watering with liquid manure, and another after stoning, and that will keep down red spider, which will cause the leaves to fall. If you wish for late Peaches, plant such kinds as Late Admirable, Walburton Admirable, Stirling Castle, and Barington.

LAWN WEEDY (H. P. E.).—We advise you to persist in removing the weed from this time to March in mild weather, and early in that month give a good dressing of rotten manure, and rake it well in with an iron rake. With the first prospect of rain in April sow of *Lotus corniculatus* minor, 1 lb.; *Trifolium minus*, 4 lbs.; *Trifolium repens*, 2 lbs.; *Cynosurus cristatus*, 4 lbs.; and *Festuca duriaccula*, 4 lbs. Roll well after sowing if the ground is dry, but do not roll again for a month, then roll twice or thrice a week, and if not mown for six weeks after sowing all the better, then mow and keep well rolled. You may give 1 cwt. of Peruvian guano during wet weather in May. The quantities named are for half an acre.

BELLADONNA LILIES NOT FLOWERING (L. R.).—The bulbs from being taken up before they were matured, or from being kept too long out of the ground, have been weakened, and had not vigour to support the bloom. You can hardly expect them to flower next year. We advise you to have them potted, and keep them constantly on a shelf near the light in the greenhouse, with a pan of wet sand under them. The sand ought never to become dry, not even when the plants are dormant. The bulbs should be placed in small pots, and have good drainage; good yellow loam from turf, with about one-third of leaf mould and one-sixth of sand intermixed, will form a good compost. Give little water until the bulbs are growing freely. Keep them well supplied until the growth is complete, then lessen the supply, and discontinue it altogether when the foliage becomes yellow. Do not pot until the roots split the pots, or the drainage becomes defective.

REMOVING A LARGE YEW TREE (Idem).—The Yew may be safely removed, care being taken to preserve a good ball, and to keep the spade at a good distance from the stem. No time should be lost in proceeding with the operation. It would contribute to success if the head were cut-in in spring. The Yew will push freely from the naked or thick branches, even better than any other tree or shrub.

CRUSTED BONES AND SUPERPHOSPHATE OF LIME FROM ROSES (Deroniensis).—Half-inch bones and superphosphate are both good manures for Roses. The former should be put in near the roots for the fibres to run into; the latter may be either put in as above, or over the surface, and lightly covered with soil.

ESTIMATE OF A FEW ROSES (Idem).—"I do not possess Princess Mary of Cambridge. It is a very good Rose. Charles Verdier, sive Marguerite de St. Amand came out, is, in my judgment, the best light-coloured Rose. Miss M. Dombria is very fine, but subject to a tick in the side. Mr. Keynes had at Blandford beautiful trebles of the Princess Mary of Cambridge and Miss M. Dombria, also of Xavier Olibo. I am not quite sure that Charles Verdier will be as free a bloomer as Marguerite de St. Amand. It bloomed freely with me, but I have heard complaints of its not opening. It is a very full Rose, and perhaps wanted water. Its wood is the same as that of Victor Verdier.—W. F. RADCLIFFE."

HEATING A SMALL GREENHOUSE (Subscriber, Bandon).—We do not think that you will be able to regulate the temperature of your house by heating a boiler with a lamp. We would have more faith in a large lamp with a tube and globe, an inverted funnel suspended over it, and a pipe from the funnel leading into the open air. We do not know the slow-combustion stove to which you allude, but we will undertake to make any stove a slow-combustion one, by nicely regulating the admission of air by the asphit door. If we were in your place we would have a small iron stove, say 23 inches in height, and 14 inches in diameter, which would allow you to have a fire 6 or 8 inches wide, without the fire touching the outside iron. This, with a plate-iron funnel going through the roof, will keep your house warm. The simplest plan for the funnel is to take out a square of glass, and insert a similar square of zinc or iron with a hole in it for the funnel to pass through. Even by using papered charcoal in a stove, we would have no faith in it without a pipe to let out the products of combustion.

PLANTING A GARDEN (A. Mechanic).—We cannot undertake to plant gardens, but if you will tell us your appliances and means, and what you intend doing, we will give you our best offices. In addition to the little books ordered, we would recommend Keane's "Out-door Gardening," which may be had from our office for twenty stamps. Meanwhile we would say, that though we would commend the carefulness with which you have pencilled your plan, we cannot see how you can make it work, so as to have a border on three sides at least, 18 inches wide, a gravel path round the four sides of the square, and the inside of the square itself laid out with five clumps, a large oval in the centre, and four triangular beds at the corners, and these beds to be surrounded by and divided from each other by grass, and all this in a space of 14 feet by 8 feet. Even supposing that there could be room, we would alter the plan so as not to give almost all the space to the centre bed, merely making that the largest, and the others in proportion, as at present that bed, simply from its size, would preponderate over all the rest of the garden. Perhaps, however, we read you wrong, and the central part surrounded with grass is of itself 14 feet by 8 feet. If so, the above remarks as to relative size will hold good, and as you show no grass on the border side, neither would we have grass in the central part, as, if not much more than a foot wide, it will always be difficult to manage. The square corners of your walk will always be unpleasant when the space is so small and the walks so narrow, and you would gain much in comfort, and the outline would be more artistic, if you have only one clump in the centre—namely, a circle or oval, make your walk more circular round it, and add in proportion to the width of the border at the four corners. As we do not know your conveniences we cannot tell you how to provide for next season's display. You could plant the white-leaved *Cerastium* in little bits as an edging to your border now. You could back that by dividing roots of *Daisies* and *Violas*, say red *Daisies* and yellow *Violas*. You could also do your central beds with *Wallflowers* and *Rockets*. We need not say how pretty you could have it in spring with *Crocuses*, *Snowdrops*, *Tulips*, *Hyacinths*, and *Narcissus*. If you have any place under glass, or a spare window near which to set a table, you might sow various kinds of hardy annuals, as different *Nemophilas*, *Candytuft*, *Sweet Alyssum*, *Virginian Stock*, *Slanes*, the dwarf kinds, *Eschscholzia*, &c., to be transplanted in March, when they would bloom early, and the cost of the seeds would only be a few pence; but it would be useless for us to make suggestions which you might not be able to act upon. If you attempt to rival the fine lines of colour of fine-foliated plants which you have seen in the parks of London, you must have glass, and be furnished with heat of some sort. If you had a spare room with plenty of light you might raise plants in a small box, with a place for hot water beneath; but you would have to harden them off by degrees, so as to be able to stand out of doors. If you have had little experience we would advise you at first to try bulbs and dwarf hardy annuals. The annuals we have named, if sown under protection now, would come in early, and would be succeeded by others of the same kind sown in March. As edgings to such small gardens *Box* answers well, neat tiles better, and flints and pebbles of small size are not to be despised. With a brush and colour, you may give these flints or small stones any colour you like.

FORM OF ORCHARD HOUSES (X).—Span-roofs are preferable to lean-to houses according to circumstances. Span-roofed houses admit more light, and may be so placed as to take full advantage of the morning and afternoon sun, and where no wall exists they will be cheaper when the space enclosed is considered; but if to be kept at a high temperature they will cost more in heating. Lean-to's against a wall are much warmer in a cold place when they face the south, and provided walls are already there, the fronting them with glass is never inadvisable. In other cases the *Vine* borders may be made entirely outside, leaving the inside borders for other purposes, and in that case the front wall may be solid; but if on piers or arches, and only 2 feet of a border could be given to the *Vines* inside, it would be better, as the *Vine* stems would be secure at all times. We take many *Vines* through a hole in the front wall, but several times, do what we could, we have had the *Vine* stems gnawed by rats. The merit of houses that rise from low piers in front, be they span or lean-to, is that you depend on the glass roof entirely for light, and as that roof is generally rather steep, the plants trained under it are better fitted for early and late crops. In attending such houses, most of the work must be done from the outside, or you must stoop considerably in doing it from the inside. In a lean-to or span-roofed house, where the sides are high enough to permit a person to walk near the side inside, the flatness of the roof is counterbalanced to a certain extent by the light in winter, late in autumn, and early in spring, that passes directly through the front glass. Such houses are best for plants or ornamental purposes, as you can enjoy them better from being able to walk about easily. Where mere fruit culture is concerned, the roof rising from piers or a low wall, say a foot or 18 inches above the ground, does very well; but then utility more than elegance or mere convenience are the main objects.

HYACINTHS IN POTS (A. Constant Subscriber).—We should prefer a mixture of sand and leaf mould to mere cocoa-nut fibre refuse as soil for them.

FRUITING VINES (Reader).—We have no faith, as a rule, in taking two bunches instead of one from every shoot or spur of a *Vine*. It is perfectly impossible to tell you what quantity of water your inside *Vine* borders will require; but this we can say, keep the roots rather dry, not too dry, in winter; water so as to have the ground somewhat moist as growth commences; give more water as growth proceeds; and just manage to have the surface somewhat dry as the *Grapes* ripen. Before colouring, if you are sure by personal examination that the soil is moist enough right through, a damping of the surface will be all that will be required. With such a border it will not be easy to overwater in the growing time. Cold water should not be used.

SOWING ROSE SEED (P. S.).—The hips should be gathered when ripe, early in November, and kept entire in a flower pot filled with sand. At the end of February or beginning of March they must be broken with the fingers and the seeds sown in pans, which should be deep—not less than 8 inches in depth. They ought to be well drained, and filled to within half an inch of the rim with two-thirds loam from turf, and one-third sandy peat or leaf-mould, adding sand if the soil does not contain enough. The seeds should be placed rather thinly, and covered with half an inch of fine soil. The pans should have a good watering, and be plunged in the open ground in a sheltered but open situation. They must be protected from mice by a covering of very small-meshed wire netting, which will also keep the soil moist from the shade afforded, space being allowed

between the soil and wire for the plants to come up; three-quarters of an inch will be sufficient. The soil should be kept moist. The plants will appear in May or earlier, and when they have three or four leaves they may be taken up and potted in small pots, be placed under a hand-glass for a few days, planted out in good rich soil, and they will then make strong shoots fit for budding in August or September. Very often the seed does not vegetate until the second spring; the pans, therefore, should be allowed to remain until May or June of the second year.

ELM TREE INJURED BY INSECTS (A Subscriber).—The bark falling off suggested that the *Scolytus destructor* had assailed the tree, for which we know no remedy; but the holes "large enough to admit the point of a little finger," intimate that the ravager is the caterpillar of the goat moth, *Cossus ligniperda*. It may be sometimes destroyed by thrusting wire up the hole, but the mischief done is irreparable.

BACK NUMBERS (Q. Reed).—The whole of the numbers you mention and the index, can be obtained from our office.

COTTAGE GARDENERS' DICTIONARY SUPPLEMENT (R. J. S.).—You can have the Supplement free by post from our office if you enclose twenty postage stamps with your address.

PEARS MEALY (South Wilts).—The *Beurré Rose Pears*, grown on a south-west wall, mealy and deficient in flavour, would probably have not been thus faulty if the soil over the tree's roots had been mulched and watered well during the late hot dry summer.

SITUATION NEEDED (J. C.).—You must write to the principal nurserymen, stating your qualifications and testimonials.

FORCING-HOUSE MANAGEMENT (P. P.).—"In-door Gardening" contains the management for each week. You can have it free by post from our office if you enclose twenty postage stamps with your address.

NIMBUS TRICOLOR (A. C.).—We only know that it is stated to be a native of Mexico, and was introduced to this country by Hartweg about 1849.

MELON APPLE TREE UNFRUITFUL (Kingsbridgeensis).—The shoot you sent is thickly covered with the Apple-scale insect (*Aspidiotus conchiferus*). Brush the stem and all the branches with this mixture:—Soft soap, 2 lbs.; flowers of sulphur, 2 lbs.; tobacco, 1 lb.; and a wineglass of spirit of turpentine. Mix the sulphur, turpentine, and soap into a paste with warm water; boil the tobacco for an hour in a covered saucepan in some more water, strain it, mix it with the soapy mixture, and then add enough water to make five gallons. A south wall is too hot a situation for the tree in Devonshire. Mulch and water often in dry summer weather.

MAIDEN FRUIT TREES (Ignorance).—A maiden plant is a tree that has never been pruned; for instance, a *Plum* stock budded this year with a *Peach* will next year have a single strong shoot from the bud inserted in the *Plum*; that in autumn is a maiden plant, and the shoot is to be cut down to two buds situated at 9 or 10 inches from the ground in order to furnish side shoots, the best two at that height being selected, as you will find explained at page 266.

SOIL FOR VINE BORDERS (G. P. R.).—You cannot make your *Vine* border with anything better than the top spit—say 3 inches deep, of a good heavy pasture. Allow this to lie in a heap for six months, and then add a load of brick rubbish, and a couple of bushels of broken boiled bones to every seven or eight loads of the turfy mixture.

POTASH FOR DISSOLVING BONES (Nemo).—The exact quantity required cannot be told, for bones differ in the amount of phosphate of lime which they contain. Cost each bone with the powdered potash, and strew a little over each layer of bones.

PIG-ON MANURE (Pigeon).—Some nurseryman or gardener in your neighbourhood would probably purchase it.

EXTERMINATING ANTS (H. Smart).—They may be driven away by repeatedly strewing guano, or pouring over their nests the ammoniacal liquor from the gas works, or you may pour into their nests a solution of Clarke's insect-destroying compound at the rate of 2 ozs. to the gallon. You may, after the fruit is set, syringe the trees with a solution of the compound, and once a month up to August, or oftener if the pest appear, doing it in the evening, or early in the morning, for ants are early and also late workers. The compound will free your trees of other insects as well as the ants, as aphids and red spider.

NAMES OF FUNGI (Durbin).—The following is a list of your Fungi; there is none decidedly edible:—1, *Lyceoperdon saccatum*, a rare species of *Puffball*; 2, *Agaricus flavicinus*, belongs to an edible group, but we do not know its qualities; 3, *Agaricus aruginosus*, poisonous; 4, *Agaricus fusciculis*, poisonous; 5, *Uromedusa auricula-jude*, the Jews-ears of the old herbalists, sometimes used in the present day by old country folk and quacks, but useless as food or physic.

NAMES OF FRUITS (H. Y.).—We have not received the stamps, and the fruit after being kept until spoiling was given away. (*Wm. McLennan*).—Your *Apple* is *Ravenscroft Pippin*. (*H. H. P.*).—1, *Margil*; 3, *Royal Russet*; 4, *Reinette du Canada*; 5, *London Pippin*; 6, *Blenheim Pippin*; 7, *Non-such*; 8, *Court-Pendu-Flat*; 10, *Yorkshire Greening*; 11, *Dumelow's Seedling*; 12, *Braddick's Nonpareil*; 15, *Cockle Pippin*; 17, *Sturmer Pippin*. (*Quince*).—2, *Vicar of Winkfield*; 3, *Passe Colmar*; 4, *Beurré Diel*; 5, *Glout Morceau*; 6, *Trompette de Jodogne*; 8, *Colmar*; 9, *Bergamotte d'Espérance*; 10, *Althorp Crasman*; 11, *Catillac*; 12, *Dummore*. (*M. H.*).—*Pears*: 1 and 2, *Gau-el's Bergamot*; 3, *Lewis Apple*; 4, *Barcelina Pearmain*; 5, *Winter Pearmain*; 6, *Warner's King*; 7, *Red Lough*; 8, *Sylhouse Russet*.

NAMES OF PLANTS (M. W. M.).—We cannot usually name plants from mere leaves. (*C. F.*).—The Bird Cherry, *Cerasus padus*. (*C. A. M.*).—*Boninvillea spectabilis*. A stove evergreen climber. Native of Peru. Propagated by cuttings. (*Mrs. Sartorius*).—We cannot name *Perlagonium*, nor any other florists' flowers from specimen flowers. They are far too numerous and differ so slightly. (*T. Rees*).—The name of the plant which has never flowered with you is *Pittosporum undulatum*, a native of Tropical Asia and Australia. The singular fungus attacking the wood in your cellar is *Oxonium arcanicum*, a mycelium. (*Casteragh*).—1, *Asplenium fontanum*; 2, *Polis longifolia*; 3, *Onychium japonicum*; 4, *Laurea Filix-mas*; 5, *Pteris sulcata*; 6, *Microcladia novae-zelandiae*. (*H. K.*).—*Pittouia argyrea* (or *Brachidium leuconervum*). (*G. D.*).—*Amaranthus tricolor*, tender annual. (*J. B. W.*).—1, *Sedum carneum*

variogatum; 2, *Begonia Daviesii*; 3, *Hedychium* apparently, but only a | tom cuneatum; 3, *Asplenium Adiantum-nigrum*; 4, *Lycopodium ro-*
leaf sent, hence uncertain. (*Rossini*).—1, *Adiantum tenerum*; 2, *Adian-* | bustum; 5, *Davallia pyxidata*.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the week ending October 27th.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

POULTRY SHOW DETAILS.

MUCH has been said and written on various occasions by exhibitors, respecting the present system of holding so many shows simultaneously. This to my mind seems suicidal, for not more than one show out of four, I think, can possibly prove a decided success as regards the quality of the birds exhibited (which is very important), and in the end a serious pecuniary loss to the various committees is the result. Besides, committees are now under the necessity of having persons to act as judges who are not possessed of the necessary qualifications, and although such persons may wish to act honestly towards all, yet their lacking the proper qualifications must inflict an injustice on exhibitors generally; so that instead of people exhibiting the various kinds of poultry with pleasure, as it ought to be, it very often proves to be a source of annoyance and vexation to many. The consequence is, that one show after another becomes a thing of the past.

To the above circumstances, with a few others, I think may be traced the total abandonment of many shows. In order that a better state of things may exist, I wish to call the attention of committees, and others, to the importance of having at all times, as far as practicable, gentlemen well qualified to perform the duty devolving upon them. I have no wish whatever to speak disparagingly of any who may be called upon to act as judges; but I think the time has now arrived when we require judges possessing a general knowledge of all the classes, and not persons who really only understand one or two classes. So long, therefore, as matters continue as they are, nothing but dissatisfaction and fault-finding can be expected. I, as an individual exhibitor, would like eight or ten persons selected to act as judges, and that they should be exclusively employed; but, of course, the committees to make their own selection from that number, and if only the exhibitors could agree as to who these gentlemen should be, better results would soon follow.

I see shows advertised that are likely to clash with each other; such being the case, one of those gentlemen might be appointed to officiate alone in all the classes at one show, while another was allowed to judge at another, and thus the great object would be obtained in each case; something like correct decisions being arrived at to the satisfaction of exhibitors generally.—EXHIBITOR.

BRISTOL AND CLIFTON SHOW.—We have just received a schedule of the Bristol and Clifton Poultry Show, its programme this time surpassing even Birmingham in the silver cups offered for competition. To Dorkings two cups each of the value of ten guineas are offered, while Cochins, Brahmas, Spanish, and Hamburgs, have two cups awarded to each, one for cocks or cockerels, and the other for hens or pullets. The Black Hamburgs will have to creep into the "Any variety" class, this useful fowl not being yet appreciated to its full value. At the last Clifton Show, it will be remembered chickens only could compete; this year, however, old and young will compete together in most of the classes. There is one lesson that we think Birmingham could learn from this young but enterprising Society. We refer to the entrance fees. While at Birmingham every exhibitor will have to send no less than four

pens, here the fancier of a single variety only will be able to compete without having to pay the obnoxious guinea, before he can show even a single pen. The entrance fees for the Bristol and Clifton Show are the same as for the Manchester and Liverpool recently held.

BREEDING DUCKWING GAME FOWLS.

IN breeding Duckwings for correct match, the "golden" rule, that "like produces like best," should be attended to; and the most correct-coloured Duckwings, especially Silver-Greys, are produced by breeding "Duckwings with Duckwings."

Selecting first-rate strains of the same colour and match, if good, but of quite different blood, the cock in crossing of one strain, the hens all sisters and of a different strain from the cock, but matching him, put two, four, or six hens to one cock; two will be the best if crossing. All should be two-year-old birds, as in their prime; if breeding in-and-in, an old cock to be put to two-year-old hens, or a two-year-old cock to old hens. Breed chiefly in April or May, or the last ten days in March, setting no more than eleven or twelve eggs under each hen.

The common way of best producing Duckwings for exhibition with the required high-coloured cocks and the Silver hens, is to breed the Duckwing cock chickens from a good Black-breasted Red cock put to Duckwing hens, and to get the pullets from a Duckwing cock with Duckwing hens, which gives the true silvery bluish grey colour, but does not breed cock chickens sufficiently high coloured. Breeding the cock chickens from a Duckwing cock with Partridge hens, is, I think, equally good, and makes more Duckwing cocks, and better on the whole, perhaps. I, however, always prefer breeding both cock chickens and pullets from Duckwings bred from Duckwings, as the cock chickens are then the true match for the pullets, and are not mongrels. No good or true-coloured Silver-Grey Duckwing pullets can be obtained by crossing with Reds, but only the yellow or yellowish pullets with brown-marked wings and shoulders, and coarse red-fawn breasts, but such as the latter, when hens, can be used for breeding the high-coloured Yellow Duckwing cocks which match them, and will do so better than breeding with the Partridge hen a second time.

The true colour for pure-bred Duckwing hens is a beautiful silvery bluish grey thickly frested with silver, with a delicate pale or silver-fawn breast, instead of the coarse red breast, and a red fawn breast is only proper to the Partridge or other Red hens. The neck hackle of the Duckwing hen should be, of course, silvery grey striped with black, less black near the head. Tail blackish grey or greyish black. I prefer the Duckwing cocks that really match such hens as these and are bred with them, but they will throw cocks according to the cock put to them, either Silver-Grey, Grey Birchen, Birchen Grey, and Yellow Birchen Duckwing cocks. The hen and not so much the cock, is the parent stock and true foundation of our Duckwings, which were first bred from Black-breasted Reds accidentally throwing Duckwing hens or pullets; and these, being perpetuated by interbreeding, produced also Duckwing cocks, the Yellows first and then the Silvers by selection afterwards. Greys are harder and gamer if rightly bred than any Yellows are, as Yellows are often softer than Reds, as when the Reds throw to Greys they throw hard birds, and when to Yellows often soft birds. I mean really good Greys and not the soft mealy colour. The high-coloured orange-copper-backed cocks are very handsome, but never breed good-coloured pullets, being only handsome cross-bred birds themselves.

Our Duckwing exhibitors seldom exhibit a real match in a pen of Duckwings, but show a cock and hens of different strains; the hens being from one strain greyer, the cock from another and yellower or higher coloured. When of the same strain the hens are often faulty, being brown-shouldered and too red-breasted. I do not approve of crossing back to the Black-breasted Reds in breeding Duckwings, but if high-coloured orange-backed cocks are required, they can best be obtained by crossing with the high-coloured Yellow-wheaten Duckwings, or the Ginger Blue Duns, or even with the Golden-cinnamon Black-breasted Reds, yellow legs, which coloured legs all three of these sorts have. Brown Reds and Ginger Reds will often give orange shoulders to Duckwing cocks, but this cross spoils the black breast for Duckwings. Orange Piles will also breed Duckwing cocks orange-backed, but this cross gives too many white feathers. Duns will breed pure Black-breasted Duckwing cocks. Crossing with Black-breasted Reds always spoils Duckwing hens in colour, but good-coloured cocks can be obtained by this cross.

I think that fair and honest exhibitors would do better if they made a rule of always exhibiting the true and pure-bred Duckwings instead of any of the crossed birds. The late Lord Hill, of Hawkstone, Salop, was, I have been told, the best Silver-Grey breeder in England, and would not allow a single red feather in his runs or walks, especially in breeding.

The great objection to breeding the Silver Duckwing Greys in-and-in is, that the cocks, and sometimes even the hens, become too pale, and are liable to have the silver-mealy breasts, also the white or grey-spotted black breast in the cocks.

I have known "Duckwings bred with Duckwings" for a quarter of a century, crossing with the same colour from different but good strains, and the stock is still very good.

The Silver-Grey Duckwings are now very rare at our exhibitions, as willow-legged Duckwings are seldom or never pure Silvers, which when really pure have the white, blue, or blackish legs, and never willow or yellow legs, which latter belong to the sorts not Silvers; the willow legs to the Grey Birchen and Birchen-Grey Duckwings, and the yellow legs and yellow eyes to the true Yellow Birchen Duckwings. The purest Silvers are the mealy grey-breasted mealy-silver Duckwings with white legs and silver-pearl grey eyes, cocks' and hens' breasts the same colour; but this breed is now almost extinct.

The willow-legged Birchen-Grey or Grey Birchen Duckwings are most common of all; the red eye inclining these rather to the grey than to the yellow hackle, but the willow leg and yellow skin keeping the breed yellowish in feather. The yellow or daw-eyed breeds of Duckwings seem to have been first bred from the Light Gingers or Black-breasted Gingers with yellow eyes and yellow legs.

Our judges at most exhibitions do not, I think, in general judge our Duckwing hens well; they give attention chiefly to the cocks, and not equally to cock and hens, thus we generally see exhibition Duckwing prizes awarded to hens with brown shoulders and red breasts, which hens are all cross-bred mongrels, though they may be the right match for "their brother," a handsome high-coloured cock, also a handsome mongrel-bred bird. I think the judges should select only the silvery bluish-grey hens with the delicate pale silver-fawn breasts for their prize hens, allowing no brown wings at all, nor yet coarse red breasts, than which nothing looks worse; and a cock that truly matches such hens as these is the best Duckwing cock for a cup or prize in my opinion, whether "too silver" or not. Too much stress, I think, is laid on high colour in the back of prize Duckwing cocks.—NEWMARKET.

LORD TREDEGAR'S POULTRY SHOW.

In common with many exhibitors who signed the memorial to the managers of this Show, I did not exhibit at the Show in 1867. I am sorry to say that several who signed the memorial, nevertheless did exhibit some poultry. Under these circumstances it appears to me that the memorial is no longer binding on the remainder, and that those who like may, therefore, be free to show at the approaching Exhibition. As regards this identical Show, I believe that every effort the Committee could make, was made, and, therefore, the blame does not really attach to them, and it is, perhaps, saddling the wrong horse to make them suffer. Railways, and especially the G. W. R., rule us all with rather too iron a hand.—Y. B. A. Z.

THE SOUTHAMPTON POULTRY AND BIRD SHOW.—The entries for this Show will close on Friday, the 30th inst. We notice

some favourable features offered by the Committee to exhibitors, amongst which is an auction sale, whereby exhibitors may dispose of their prize and surplus stock. The prize list includes several silver cups for poultry, Pigeons, and cage birds; one, value six guineas, subscribed for by several breeders, is offered for the best pen of Light Brahma chickens. The prizes for cage birds are liberal.

NOTES ON FANCY PIGEONS.—No. 12.

TUMBLERS IN GENERAL.

I HAVE as yet in these notes treated of two classes of fancy Pigeons, Pouters and Carriers, including in the latter class all Pigeons that carry—viz., the Horseman, the Dragon, and the Antwerp. I have every reason to be gratified for having started the subject, as there have been, first, many and very excellent and useful papers written on Pouters; also some good papers on the Carrier class from "A FOREIGNER," Mr. Croeland, Mr. Ludlow, "AN OLD FANCIER," and others. There has been naturally enough a little difference of opinion, but I must say I have read all the communications with interest, and with, what we should none of us be above, a desire to learn by the experience and opinions of others.

It is this free communication of our different views which leads to acquirement of knowledge, and in the case of Pigeons will tend to raise the fancy to the position which I hold to be its due—namely, a high position. Rightly, I think, says Dr. Bechstein, "Concerning the domestic Pigeons in their several varieties much might be said. Of Pouters, Tumblers, Jacobins, Shakers, &c., a volume might be written, and a very interesting one too. The extraordinary changes of plumage, and modification of form which have been produced in these birds are equally curious and interesting." Then, we must remember, that whatever is tame or domestic tends to make up and complete that beautiful thing we call a home. Hood, speaking of a dreary, forsaken, miserable-looking house, says—

"No dog was on the threshold, great or small;
No Pigeon on the roof—no household creature—
No cat demurely dozing on the wall—
Not one domestic feature."

The absence of all these made the house dreary and forsaken; it did not look like a home.

Pigeons can be kept where fowls cannot live in comfort; they will prosper where even flowers will not grow; they can take the country into London, and help to make for the humblest citizen a home.

But it is not of Pigeons generally, but of one variety I must speak at this time. Pouters and Carriers have had their description and praise, now comes the next class, the trim, compact, dainty little Tumblers. They boast not quite the ancient lineage of the Carrier and the Pouter, but the Almond Tumblers began to be honoured about a century ago, and they have increased in beauty with time. But of them by-and-by; this paper is to treat of common Tumblers—yes, common Tumblers. And what a good thing it is that common things, things easiest to be had, yet afford great pleasure. The common little flower garden gives as much pleasure to its owner, he not being able to have more, as a rare garden does to its owner. The Linnet in its cage affords its young master or mistress as great enjoyment as in after years will the longest and lankiest Belgian Canary. So the common Tumbler gratifies its possessor, not being yet a skilled fancier, as much as the most difficult to breed and rarest Pigeon. I say common Tumblers, but then they must tumble, they must be true to their name. I object to Pouters that will not pout, to Shakers that will not shake, and to Tumblers that do not tumble. Such Tumblers are not true to their name, you look up and they do not tumble. Let them be hidden in a pie-dish at once, let the little feet that would not turn up in life show their toes uppermost through the nicely browned crust, and that too without delay. I never keep Tumblers of the commoner classes that do not, or cannot, or will not tumble. I say, "Die, impostors!" Of course, in regard to the highest class, Short-faced Tumblers, this matter of actual tumbling is not a necessity, as these birds are birds of many fancy points, rather than fliers, but I never keep common Tumblers, or Beards, or Baldheads, &c., that cannot tumble.

Not long since I was in a seaport town and found out as usual the bird shops. I was seeking Tumblers, but found none to my satisfaction. I wanted neither Almonds nor any bred from or crossed with Almonds. I found no Tumblers in the

shop except coarse, ill-shaped birds, and I not unnaturally bestowed no praise upon them. "Why, sir," said the man in the shop, "what can you want? I bought the whole flight of a gentleman, and I'll warrant they will tumble well, and keep up for hours." "But," said I, "they have not even pearl eyes." "As to that sir, nobody looks for pearl eyes now in Tumblers." "But," said I again, "look at their legs, they are partly feathered." In fact, these wonderful Tumblers were most probably bred from Rollers, with a mixture of the common Bunt, and they retained the tumbling and that was all. True, they were *tumblers*, but though I consider that their first property, yet others should be found in birds bearing that name. Some years since I used to be able to obtain well-coloured Tumblers with clean coral legs, neat heads, but with no mixture of either Almond or Roller blood. They flew high, kept up well, and tumbled sufficiently, and their form was symmetrical; but now how rarely are these seen! but in their place a countless herd of coarse, patchy-coloured birds. I should like fanciers to reject these and get birds pleasing to the eye, fairly round-headed, full-breasted, neatly made, but strong nevertheless. Feathers on the legs are wrong; the Tumbler-shape requires the neat, unfeathered, clean, coral legs and feet.

No Pigeon is more attractive than the Tumbler, and it retains its hold upon the affections for years. It is a tame bird, walking confidently and confidently among our feet; cooing and displaying its airs near you, while no eye can fail to be pleased with its dapper little figure. There are other things in their favour—they breed well, are excellent parents, save the Short-faced ones, and they are very good eating. "What! eat your pets?" "No, my dainty lady, I eat them before they grow to be pets." There is always this advantage in keeping Pigeons, that you can eat them and so get rid of the faulty or the superabundant, unlike those who keep Doves, who sometimes bore their friends in begging them to accept pairs. One lady I knew who kept Doves, used to prick their eggs so as to prevent their producing young. Anything to stop the terrible fertility of her pets, for, oh! the outlay for cages, and the coaxing mammas to allow their young hope fuls to accept a pair of Doves. Now, we Pigeon-fanciers are never in such trouble.

In common Tumblers I would include all the varieties that are larger than the Short-faced birds. Thus I would take the Baldheads and Beards, and if I must the Rollers, which seem the lineal descendants of the Dutch Tumblers of the older writers. The Rollers, after the novelty is over, are not pleasing. They seem to overdo and are falling, rather than tumbling, head over heels. The House, Air, and Ground Tumblers must be still worse, theirs is not a pretty gymnastic feat but a sad misfortune.

The best and truest-bred common English Tumblers that I have ever known, have been either Red or Buff; the latter are charming pets, but look better on grass than on gravel. It would not be ill-spent money to offer at all large shows prizes for well-bred genuine English Tumblers.—WILTSHIRE RECTOR.

P.S.—I beg to thank "A FOREIGNER" for his two excellent articles entitled "Management of Pigeons in Health and Disease," and "Some Notes on Pigeons."—W. R.

LIGURIAN BEES AS HONEY-GATHERERS.

The prolific character of the Italian queen has been abundantly testified to in the Journal, but very little has been advanced regarding the honey-gathering powers of her offspring. After four years' experience, it is my conviction that a great return of honey is not to be expected from a pure Italian colony. In this district the produce from Italians has not been equal to that from black stocks, and it has fallen very far short of that derived from hybrids; in fact, the return from pure Italians has been quite a failure. I hoped for great results this last beautiful summer from a very strong stock, but at the close of the season it had amassed very little more honey than would suffice to carry it comfortably through the coming winter. A very different state of things was presented by my hybrid stocks; they literally groaned with honey, and sent out as many and as large swarms as hives of the purest-bred bees. I would, therefore, recommend those parties who wish a good honey harvest to have their stocks furnished with "hybridised" queens.

These views may not be entertained by many, but they accord with what has come under my own observation.

The pure Italian bee cannot endure such a lengthened confinement in its hive as either the black bee or the hybrid. It consumes more honey, and is more susceptible of cold. In a low temperature I have often seen it fly out, never to return, when blacks and hybrids found their way back to their homes with comparative ease. But with all its defects I greatly admire the Italian bee, and would be the last to discard it from my apiary. At the same time there is no reason why its merits should not be canvassed, and I shall be glad to hear what Mr. Lowe, with his forty pure stocks, or others, have to say on the subject.

The idea of feeding a hive of bees previous to driving it, as propounded by Mr. Pettigrew, is very good, and should not be lost sight of. Late in autumn, when the weather is cold, it is often extremely difficult to dislodge bees. Perhaps the end aimed at by Mr. Pettigrew would be speedily attained were the stock hive, on being turned up, to be sprinkled with a little lukewarm syrup immediately before covering it with the empty skep.—R. S.

THE NATIVE HONEY-BEE OF MEXICO.

In the hives of the domesticated bees of Mexico we meet with a structure altogether peculiar. They exhibit little of the regularity of construction which characterises the hives of the bees of the old continent, and are far inferior in this respect to the habitations of wasps. In one particular they approximate to the nests of the European humble bees; the honey which they contain is deposited in large bags distinct from the common cells. It is somewhat singular that so interesting a point of natural history has never been particularly noticed; our previous knowledge scarcely extending beyond the facts, that some of the bees of America form nests, like those of wasps, attached to or suspended from trees, and covered by an outer case constructed by themselves; while others, incapable apparently of forming this outer crust for their hives, seek cavities ready formed for their reception, and in them construct their habitations. Instances of each of these kinds of hives are mentioned by Piso in his Natural History of both the Indies; and Hernandez, in his History of Mexico, states that the Indians keep bees analogous to ours, which deposit their honey in the hollows of trees. Little information beyond that furnished by these older writers is contained in more modern works; and even the Baron von Humboldt, to whose acute observation science is indebted for so many discoveries respecting the New World, appears not to have noticed with his usual care the peculiarities of its bees. Had that distinguished traveller directed his attention to the habits of the species which he collected during his memorable journey, M. Latreille would doubtless have given to us the necessary details in his excellent Monograph of the American Bees, included in the "Observations Zoologiques" of M. Humboldt. In the valuable essay prefixed to this Monograph, M. Latreille has collected from authors numerous statements relating to the habitations of bees, and especially of those of America; but has added to them no new facts as regards the hives of the New World. The subject may, therefore, be regarded as altogether novel, and as requiring some little detail in its explanation.

In the domestication of the bees of Mexico but little violence is done to their natural habits. Inhabitants, in their wild state, of cavities in trees, a hollow tree is selected to form their hive. A portion of it of between 2 and 3 feet in length is cut off, and a hole is bored through the sides into the hollow, at about its middle. The ends of the hollow are then stopped up with clay, and the future hive is suspended on a tree in a horizontal position, with the hole opening to the cavity directed also horizontally. Of the hive thus prepared a swarm of bees speedily take possession, and commence their operations by forming cells for the reception of their larvæ, and sacs to contain the superabundant honey collected by them in their excursions. Two such hives, completely formed and occupied, were brought to England, safely packed in recent hides. One of these was forwarded to M. Huber, eminently distinguished for his highly interesting observations on the manners of bees; the other was presented to the Linnean Society. The latter was carefully divided longitudinally, so as to expose its interior.

The eye of an observer accustomed to the regular disposition of the comb in the hive of the European bee, is at once struck with the opposite directions assumed by it in different parts of that of the Mexican. Instead of the parallel vertical layers of comb, we have here layers, some of which assume a vertical, while others are placed in a horizontal direction; the cells of

the latter being the most numerous. The cells, of course, vary in their direction in the same manner as the comb which they form; those of the horizontal layers of comb being vertical with their openings upward, while the cells of the vertical comb are placed in a horizontal direction. In the horizontal cells the mouths are partly directed away from the entrance to the hive, and partly towards it; the former direction being given to those cells which occupy the middle layers of comb, and the latter to the cells which are placed on the side of the hive opposed to the opening. All the combs, both vertical and horizontal, are composed of a single series of cells applied laterally to each other, and not, as in the European hive bee, of two series, the one applied against the extremities of the other. The horizontal combs are much more regularly formed than the vertical, the latter being broken and placed at uncertain distances, while the horizontal are perfectly parallel with each other, forming uniform layers and placed at equal distances. Between these parallel combs are processes of wax, partly supporting them and passing from the base of one cell to the junction of others in the next layer. These columns are considerably stronger and thicker than the sides of the cells which they support.

The cells appear to be destined solely for the habitation of the young bees; for in all that have been examined bees have been found. The bee is placed in the cell with its hinder parts directed towards the mouth of the cell, which is covered by a granular mass, probably composed of the pollen of plants. The form of the cells is hexangular, but the angles are not sharply defined, and the mouth is scarcely, if at all, thicker than the sides. In their dimensions and relative proportions they differ materially from those of the European, and still more from those of the Indian bees, as may be seen by the subjoined table:—

	Mexican.	European.	Indian.
Diameter of cell	25	23, 31	19, 27
Depth of ditto	4	5, 6	4, 6

All of those which are visible appear to be uniform in size; nor without the destruction of the specimens can it be ascertained whether there are any larger cells for the larvae of the males or of the queen.

The combs are placed together at some distance from the opening of the hive, and form a group of an oval shape, consisting of five horizontal and parallel layers, occupying the part most remote from the opening; of an interrupted vertical layer applied to the side opposed to the opening; and of two principal, and two or three smaller, vertical layers in the middle. The whole of these are supported by wax, spread out into layers borne on processes of the same material, resting either on the wood of the cavity, or on other parts of the fabric of the comb. In these processes and layers of wax are numerous openings of various sizes, at once admitting of ready access for the inhabitants to every part of the hive, and economising the use of the material of which they are constructed. Some of the openings are of large dimensions. The entrance into the hive is continued into a long gallery, which, to judge from the direction taken by a flexible substance introduced into it, leads beneath the combs to their very extremity. It is therefore probable that at the extremity the work of building commenced.

Surrounding the combs are several layers of wax as thin as paper, irregular in their form, and placed at some little distance from each other, the interstices varying from a quarter to half an inch. One of these supports a vertical comb; the others are connected to the combs only at their edges, or by processes or layers of wax. Externally to these are placed the sacs for containing honey, which are generally large, and rounded in form. They vary in size, some of them exceeding 1½ inch in diameter. They are supported by processes of wax from the wood of the cavity, or from each other, and are frequently applied side by side, so as mutually to afford strength to each other, and to allow of one side serving equally for two sacs. Their disposition is altogether irregular, and bears some resemblance to that of a portion of a bunch of grapes, rendering it probable that Nierenberg was acquainted with a similar nest, if not actually that of the same bee, although he denies to the one described by him the power of constructing combs. Some of the honey-sacs are placed apart from the others, forming a distinct cluster of the same general appearance as those immediately adjoining the comb.

From this singular position of the honey-sacs a most important advantage is obtained by the cultivators of the Mexican hive bee. To possess themselves of its honey it is unnecessary

to have recourse to the means adopted in Europe for stupefying, or even destroying, the inhabitants of the hive. All that is necessary is to remove the plug from the end of the cavity employed as a hive, to introduce the hand and withdraw the honey-sacs. The store of the laborious bee is thus transferred to the proprietor of the hive without injuring, and almost without disturbing, its inhabitants. The end of the hive is then again stopped up; and the bees hasten to lay up a fresh supply of honey in lieu of that of which they have been despoiled, again to be robbed of their precious deposit. A hive treated in this way affords during the summer at least two harvests.

The honey is usually pressed from the sacs by the hand. Its consistence is thin, but its flavour is good, although inferior to that of the whiter honey furnished by the Spanish bee (probably our *Apis mellifica*, L.). It does not readily ferment, some of that contained in the hive being perfectly sweet and grateful even after its arrival in England.

The wax is coarse in quality; its colour is dark yellowish brown. The whole of it appears to be similar in texture and properties, as well that used in the construction of the cells, as that which is applied to the coarser work of forming honey-sacs and supports: the only remarkable difference being that in the former it is apparently paler, probably owing to the layers employed being considerably thinner and more delicate. Of the varnish-like substance known by the name of propolis, and used by the European bees to cover the foreign substances with which they frequently come in contact, scarcely any vestige is exhibited, although we have evidence of its existence. The wood of the inside of the hive, except where wax is applied to it, is perfectly naked.

The hollow of the trunk forming the hive now before us, is irregular in its outline, and varies in its breadth in different parts. Its average diameter, however, is about 5 inches. The length occupied by the cells is more than 7 inches, and the total length between the extremities of the honey-sacs is 15 inches. The number of its inhabitants, assuming that of the cells as a guide, must have been considerably under a thousand; a number trifling in comparison with that contained in the hives of the European bee, which commonly amounts to as many as twenty-four thousand.

The bee by which this nest is constructed is smaller than the European hive bee, its abdomen especially being much shorter than that of our common species. Like all those American bees which approach in their habits to our European race, it is readily distinguished from that, and from all other hive bees yet discovered in the Old World, by the form of the first joint of its hinder tarsi, which is that of a triangle, with the apex applied to the tibia. On account of this variation in the form of a part so important to the economy of bees, modern entomologists have universally agreed in the propriety of regarding the American races as constituting a distinct group from the bees of the Old World. M. Latreille has gone further by subdividing the American bees into two genera; *Melipona*, in which the mandibles are not toothed; and *Trigona*, in which these organs are dentate. Of the propriety of this subdivision, which hitherto seemed to be supported by the general appearance of the insects referred to each group, the examination of the bee whose nest has just been described has given rise to considerable doubts. In it one of the mandibles is toothed, and the other is nearly entire. Its technical characters, therefore, are intermediate between the two genera, with a leaning towards *Trigona*; but its general appearance is entirely that of a *Melipona*, approaching very closely to that of *Melipona favosa*, Latr., *Apis favosa* Fab. That it cannot be that species, or any of the nearly-related ones described by M. Latreille in the "Observations Zoologiques," is evident from the dentation of its mandible, and it may, therefore, be regarded as new to science. The name of *Melipona Frecheii* which is here proposed for it, is a just tribute to the observer, to whom we owe the first opportunity possessed in Europe of becoming acquainted with its habits and economy.

Some curious stories are related by the possessors as to the manners of these bees, one of which deserves to be recorded. They assert that at the entrance of each hive a sentinel is placed to watch the outgoings and incomings of his fellows, and that this sentinel is relieved at the expiration of twenty-four hours, when another assumes his post and duties for the same period. On the duration of this guard some doubts may reasonably be entertained, but of its existence ample evidence was obtained by repeated observation. At all times a single bee was seen occupying the hole leading to the nest, who on the approach of another withdrew himself within a small cavity,

apparently made for this purpose on the left-hand side of the aperture, and thus allowed the passage of the individual entering or quitting the hive; the sentinel constantly resuming his station immediately after the passage had been effected. That it was the same bee which had withdrawn that again took his station in the opening, could not be mistaken; for his withdrawal was only into the cavity on the side of the hole, in which his head was generally in view during the brief interval while the other was passing; and that head again immediately started forward into the passage. During how long a time the same individual remained on duty could not be ascertained; for although many attempts were made to mark him by introducing a pencil tipped with paint, he constantly eluded the aim taken at him, and it was therefore impossible to determine with certainty whether the current reports concerning him were or were not founded in fact. With the paint thus attempted to be applied to the bee the margin of the opening was soiled; and the sentinel, as soon as he was free from the annoyance he suffered from the thrusts repeatedly made at his body, approached the foreign substance to taste it, and evidently disliking the material, he withdrew into his hive. The hole was watched to see what would be the result of this investigation of the substance, and a troop of bees was soon observed to advance towards the place, each individual bearing a small particle of wax or of propolis in his mandibles, which he deposited in his turn upon the soiled part of the wood. The little labourers then returned to the hive, and repeated the operation until a small pile rose above the blemished part, and completely relieved the inhabitants from its annoyance.

If the existence of such a sentinel as has just been described can safely be admitted, his utility would be unquestionable, as being at all times prepared to encounter a straggling stranger, or to give warning of the approach of a more numerous body of foes. Such foes actually exist in moderately-sized black ants, which sometimes in small, and occasionally in large, bands attack the hive, and between which and the industrious bees desperate conflicts often take place. In these struggles the bees generally obtain the victory; but they are occasionally mastered by the overpowering numbers of their opponents.—(*Appendix to Beechey's Voyage to the Pacific and Behring's Strait.*)

LARGE HIVES.

FIVE AND TWENTY years ago I wrote a short treatise on the history and management of bees, which was printed in the first six numbers of the *Gardeners' Chronicle*, for the year 1844. I then ventured to assert that all the instructions given by myself, and all the books that ever have been, or ever will be published on the subject, will be of little service to the bee-keepers of England, unless they use hives very much larger than those in general use. In another treatise on the profitable management of bees, which appeared two years ago in the pages of a Scotch periodical, I stated that no greater mistake could be made in bee-keeping than that of using small hives. What would an intelligent agriculturist think of a farmer tilling his land with Shetland ponies? What would he think of a farmer's wife expecting large eggs and large profits from Bantam hens? and what are we to think of the bee-keepers of England who look for harvests of honey from hives hardly large enough for hens' nests?

Let us for a moment look into the philosophy of this question. A healthy queen bee lays upwards of two thousand eggs a-day in the height of the summer. She lays as many eggs in a small hive as she does in a large one; but in a small hive, such as Neighbour's cottage hive, such as are offered for sale in Manchester, there is not room for more than one-quarter of the eggs laid by a queen. Three-fourths of the eggs laid are therefore lost, never hatched. But are you quite sure that the combs of a large hive are as well filled with brood from the eggs of one queen as the combs of a small hive? Yes. I have seen a hive capable of holding 160 lbs. weight of honey, brood, and bees, every cell of which was filled; in fact, I have never seen the laying powers of a queen overtasked. Why, then, cripple the industry of the bees by putting and keeping them in small hives? It is a perfect marvel to me that argument, logic, or figures are necessary to convince bee-keepers of the folly of using small hives. If they could manage to shake off their prejudices, the exercise of a little common sense afterwards would do the work for them. Three hundred navvies can do more work than one hundred. Fifty thousand bees in a large hive can gather more honey, hatch more brood,

send off larger swarms, than twenty thousand bees in a small hive. In fine weather the bees of a small hive gather from 1 lb. to 2 lbs. per day; those of a large one about 5 lbs. In one instance, to my knowledge, the bees from a large hive gathered 20 lbs. weight in two days. In advocating the use of large hives, I freely admit that in fine seasons considerable stores of honey may be obtained from small hives; but taking one year with another, the profits of small hives are inconsiderable.

The sizes of hives which I have recommended are:—First size, for first-early swarms, 21 inches wide by 12 deep; second size, for later first swarms, 18 inches wide by 12 deep; third size, for second swarms and turnouts, 15 inches wide by 12 deep.

The first size holds more than 100 lbs. of honey, the second above 80 lbs., and the third above 50 lbs. In favourable seasons for honey-gathering they have to be enlarged by eking or by supers. An eke is simply four or five rolls of an old hive of the same width put underneath a hive. For this purpose, I generally use riddle rims 4 or 5 inches high. It is not necessary to adhere to an exact size, say 12 inches deep. It is wise to have all hives of certain widths, so that the same ekes will answer and fit year after year—that is, 15-inch hives and 15-inch ekes, and so on.

The reader will bear with me if I venture to warn him against adopting the large sizes all at once. A swarm from a small hive would not fill a large one the first year. Therefore it would be better to begin with the 15-inch and 18-inch hives, having a depth of 10 inches. The difficulty with me is to obtain hives large enough. There is no one in this locality can make proper hives. I asked an old uncle of mine in Scotland to make sixty of the three sizes mentioned above, but he made me only thirty-four, and some of them far too small. Of course I could obtain wooden hives of any size I liked, but wooden hives should never be used if straw ones can be obtained. The moisture of bees is condensed on the sides of wooden boxes at certain seasons, and this condensed moisture moulds and rots the combs. A common straw hive, well made, is incomparably better for bees than the best and most costly boxes ever produced.

If such large hives are used with great advantage and profit in apiaries managed on the swarming or multiplying system, surely it is desirable to adopt them where honeycomb only, and not swarms, are sought. If the Ayrshire or Stewarten hives were made twice as large and properly managed, much more honey would be obtained. If Neighbour's hive were thrice as large as it is, and the three little holes in the crown or top of the hive were made ten times larger, say 4 inches each in diameter, ten times more honey would be obtained from it than at present. I do not recommend either of these hives, or any other that is meant to prevent bees from swarming, because I know that the swarming system is the most natural and profitable one; but what I mean is, that hives managed on the non-swarming principle should be of considerable dimensions.—A. PERTHREW.

BUTTER IN SACKS.

A CORRESPONDENT of the *Rockford Register*, writing from Olympia, gives the method used on the Pacific coast for preserving butter:—

"I think the dairymen here have an art in the management of butter that might be turned to good account at the east, but which I never saw practised till I came to this coast—I allude to the manner of putting up butter for market. Perhaps necessity was the mother of this invention, but that makes the invention none the less valuable. Here such a thing as a butter firkin or a stone jar to pack butter in is unknown; but all butter is packed in muslin sacks, made in such a form that the package, when complete, is a cylinder 3 or 4 inches in diameter, and from 6 inches to a foot in length. The butter goes from the churn, as soon as worked over, into the cylindrical bags, made of fine bleached muslin. The packages are then put into large casks containing strong brine with a slight admixture of saltpetre, and by means of weights kept always below the surface. The cloth integument always protects the butter from any impurities that chance to come in contact with the package, and being always buried in brine, that protects it from the action of the air; and it has been ascertained by trial that butter put up in this way will keep sweet longer than in any other way. Besides, it is found easier and cheaper for the manufacturer than to pack either in firkins or jars. And for the retailer, there is no telling the advantage on the score

of safety and convenience. These rolls of butter can lie upon his counter as safe from injury, from dust or other contact, as bars of lead—can be rolled up for his customer in a sheet of paper with as much propriety as a bundle of matches. If the consumer, when he gets home, discovers specks of dust upon the outside of the eack, he can throw it into a pail of pure cold water, and take it out clean and white. As he uses the butter from day to day, with a sharp knife he cuts it off from the end of the roll in slices the thickness to suit his wants, peels off the cloth from the end of the slice, leaving it in tidy form to place upon the table. This improved manner of packing butter first caught my eye in the market of San Francisco, where I saw cords of it piled up like pigs of lead. The simplicity and great value of the improvement so impressed me that I wondered the Yankees had not long ago found it out."

DO BEES HUNT BY SCENT AND SIGHT?

DR. ALFIELD, in "The Bee Flora of Germany and Switzerland," adduces some plausible reasons in support of the assumption that bees discover the places where honey may be obtained by the sense of sight and not of smell. Is it not quite as reasonable to infer that their discoveries are not confined to either, but result indifferently to both? Having had some experience in tracing bees in their wild state, this has been our conclusion from the results of several experiments made in hunting them to their homes.

If a hunter will go into a forest and uncover his bee box, without any other preparation, he will probably find a bee lured to the exposed store, after a while, if he has the patience to wait. Having succeeded in this and permitted the laden bee to depart, let the hunter remove to another point remote from the first position, open his box, and ignite some honey, and see if his last vigil is not much shorter than the first one. Such has been our experience, at all events, and the difference was attributed to the fact that the bees were guided to the place by the scent of the burning honeycomb rather than by the sight of the stores in the box. That other bees, observing one to have been speedily lucky in obtaining a load, watch its backward flight, and follow in the same direction, using sight rather than smell, we believe to be also true. It is in this way we account for the rapid increase in the number of bees around the honey box after the first one has carried home one load and returned for another.—(*American Paper*.)

SWEET CIDER.

SEEING that a correspondent, "H. L.," wishes for information respecting the making of sweet cider, or rather the keeping it sweet, I send the following, which used to be largely practised in Gloucestershire.

When the cider was made, or soon afterwards, it was put into a large open tub in a warm room, and some new milk added to it at the rate of about two quarts of milk to fifty gallons of cider. It was well stirred, and in a short time an artificial fermentation was produced. As soon as the cider carried a good head, it was put into "dropping bags" made of canvas. At first it will require to be put into the bags several times, till the bags become thick enough for the cider to drop through quite fine. Sometimes a little charcoal is put into the bags to thicken them. This process fines the cider, and arrests further fermentation.

Barm will do instead of the milk, but milk was considered better.

After the dropping, the cider may be put into bottles or casks, and corked up at once. Most of the cider in Gloucestershire, and adjoining counties, is so acid—"sharp"—that it would bring the tears in the eyes of those not used to it. This is caused by the long fermentation ("fretting"), sometimes for several months.—J. BRYAN, *Audley End Gardens*.

OUR LETTER BOX.

DORKING COCKEREL WITH ONE BLIND EYE (R. W. F.).—The Dorking cock is not disqualified by having had an eye destroyed. That only disqualifies which is either an indication of weakness or would appear to have been removed to conceal a defect. Thus a blind side and defective sight should be fatal to success in any bird. Two broken sickle feathers in the tail of a game cock are so unsuspicious that they considerably lessen the chances of success. It would be almost a fair inference that they

had been broken off because they were splashed or white, in either case a disqualification.

WHITE DORKINGS (An Old Subscriber).—There are both single-combed and rose-combed. We know of no difference in their qualities, but the cocks and hens must all have the same form of comb—that is, all must be single-combed or all double-combed. They are as good layers as the Dark-coloured Dorkings.

GOLDEN-PENCILED HAMBURG COCKEREL (Cheshire Subscriber).—If the cockerel is for exhibition in the chicken class, he is eligible at any time, but the older he is the better, as he is then getting rid of his spotted feathers, and his tail is becoming more accurately coloured. If for adult classes, he cannot be shown without risk of detection during the year in which he was hatched. If in an open class, unless he is a very forward bird, he has little chance against older competitors. He is seldom better than he is at from eighteen months to two years old. If his earlobes are only edged with red at ten weeks old, it is almost a certainty they will be quite white before he is ten months old, perhaps much earlier.

GAME BANTAMS—CATARRH IN FOWLS (Chanticleer).—The catarrh you mention is common when the weather first breaks up, and being attended to, has no results. We put camphor in their water, and give them bread and ale once every day. We do not admire our dietary. Give them barley or oatmeal mixed with water or milk if you have it, in the morning, some whole corn at midday, and oatmeal again in the afternoon or evening. Oatmeal is preferable to barley meal. Fowls do not care to eat buckwheat, and will not if they can get anything else. Indian corn is good for a change, but it is not good enough for constant feeding. Pollard is poor poultry food. We view this catarrh in fowls as we view it in ourselves and the rest of our fellow creatures. Cold surprises us in the midst of heat, finds us unprepared, and visits us accordingly. Those who fall back on nature and talk about wild birds, &c., must be told that our fowls have long ceased to be birds of nature; we have altered their habits, and must provide for them accordingly. The refuse kitchen and table scraps are excellent food; well-ground oats mixed with it, should be the gallinaceous turtle and venison. We have no doubt the Bantams in question are Piles, and the description would do very well for the old Worcester-shire bird of that breed. At the weight you mention, they should be hard to heat if the cock is well dubbed, and if he and his hens carry their wings well up.

AGENTS FOR SALE OF HIVES (X.).—We know of no agent in Ireland for the sale of improved hives. A good many Woodbury hives have, however been introduced into that country through private channels, and if you write direct to Mr. Woodbury, at Mount Radford, Exeter, we doubt not he will be able to put you in the way of procuring them. Back numbers of THE JOURNAL OF HORTICULTURE may be obtained from this office.

UNITING BEES (A Young Bee-keeper).—In uniting stocks or swarms there is no absolute necessity for special dealing with the queens, because the bees will in the great majority of cases settle the question satisfactorily among themselves, and many bee-keepers never trouble themselves about the superfluous queens, taking their chance of sneezes, and, perhaps, going on for years without a mishap. Still there remains the possibility of an occasional misfortune, and it is to guard against this that more advanced apiarists using moveable-comb hives deal with the queens something after the fashion described by "A DEVONSHIRE BEE-KEEPER," in page 188. It is evident that Mr. Pettigrew, in the process which he details in page 255, does not intend the operator to pay any attention to the queens; but if one be removed we always prefer retaining what we judge either from previous knowledge of her history, or from her personal appearance, to be the youngest or most prolific. However large the stock may be, there is but one queen in the hive. A brief but sufficiently comprehensive and very intelligible *résumé* of the principal facts in the natural history of the honey bee, from the pen of Mr. Woodbury, will be found in the last edition of "Bee-keeping for the Many," which may be had free by post direct from this office for five stamps.

HORSE-CHESTNUTS FOR COWS.—"An Old Subscriber" wishes to be informed whether common horse-chestnuts may be given to cows—that is, if they would be good for them in any quantity?

TO MAKE NEW ROPE PLIABLE (Alpha).—New rope can be made limber and soft at once, by simply boiling it for two hours in water. Then hang it in a warm room, and let it dry out thoroughly. It retains its stiffness until dry, when it becomes perfectly pliable.

PRESERVING PEARS (A Lady).—No variety is better than the Catillac, but several other varieties are as good for the purpose. The pears should not be more than ripe. They are in fit state as soon as the pips are black. Set the pears on the fire with sufficient water to cover them; take them off when quite soft, and put them into cold water; pare them lightly, cut off the stalks, prick each with a pin sufficiently long to reach the core, and put them again in cold water with a little alum; set them on the fire to boil until the pears are tender, then take them out, and put them in cold water for the third time. Clarify and boil some sugar, put some water to it, and when it boils add the pears, cover the pan, and give the whole a boil; skim, pour it into an earthen pan, and leave it. The next day drain the syrup from the pears, add a little more clarified sugar to it, and boil it again; pour it over the fruit, and leave it as before. The next and two successive days proceed in the same way, each time decreasing the degree of boiling; then add the pears, give the preserve a boil covered, skm and pour it into a pan, place in a stove for two days, then drain the fruit, and put it by for use.

POULTRY MARKET.—OCTOBER 28.

THE little improvement we have noted has disappeared before dull trade and damp weather. Trade cannot be worse than it is.

From observations taken near London during the last forty-one years, the average day temperature of the week is 51.5°; and its night temperature 35.6°. The greatest heat was 63°, on the 5th, 1852; and 6th, 1831; and the lowest cold 17°, on the 9th, 1864. The greatest fall of rain was 1.02 inch.

ORNAMENTAL-FOLIAGED PLANTS IN AUTUMN. SILVER-EDGED VERSUS TRICOLOR PELARGONIUMS.

GLADLY I endorse the views advanced by Mr. Robson, in page 296, as to the superiority of Silver-edged Pelargoniums over the Tricolor varieties; and I do this all the more willingly because I think that by far too great a preponderance has been and still is given to Tricolors over all other varieties of bedding Pelargoniums—I will not say to their detriment, for they have not only held their own against the gay invaders of their territorial

rights, but they have also forced upon us the conviction that, although the Tricolors may be as beautiful as they are novel, yet they are only adapted for certain purposes and places in the flower garden. Nor is it at all difficult to understand why this conviction has been forced upon us, or, rather, why this reaction is taking place, for have not Tricolored Pelargoniums been planted in every imaginable position? and, therefore, it is easy to perceive how soon a clear understanding of the true value of this attractive class of plants should be arrived at.

The great popularity of Mrs. Pollock and its progeny is not to be wondered at, for, probably, no plant of modern introduction has created a greater sensation in the horticultural world, and this, too, in an age so sensational as to perhaps encourage the introduction of many worthless novelties. To my mind the improvement which is really wanted in Tricolored Pelargoniums to render them really effective for massing and for being viewed from a distance, is a much deeper margin, of a clear bright yellow, or white, as the case may be, and a somewhat more vigorous habit of growth, as this would in a great measure set aside the objection which is taken to them when so planted, on the score of heaviness. Perhaps Mrs. Pollock is never better appreciated than when forming part of a ribbon border arranged somewhat in the following order:—First row, *Cerastium tomentosum*; second row, *Lobelia speciosa*; third row, Mrs. Pollock; and fourth row, *Coleus Verschaffelti*.

That some harm has been done to the pure Silver-edged varieties I am ready to admit, because owing to the great attractions and interest which the increasing of Tricolored varieties has offered to the cross-breeder, but little attention has been paid to supplying a want which must be felt by all lovers of the flower garden, and that is a variety having the pure white marking of Perfection, combined with the broad upturned leaf margin and fine compact habit of growth of Flower of Spring. In advocating the introduction of a kind possessing such desirable qualifications, I would not wish for one moment to detract from the great merits of Flower of Spring, considering it, as I do, to be unequalled by any of its class, as I have before stated in the pages of this Journal; but I think that a pure Silver-edged variety, equal in all other respects to Flower of Spring, would at once enable us to dispense with all those sorts having such a loose habit of growth as Alma, Jane, Bijou, and Perfection. Not only for this

defect should these kinds be discarded, but also for the objectionable downward curve of the foliage, which causes the green centre to become so elevated as to be more conspicuous than the white margin, and this more especially when viewed from a distance.

My experience of *Gnaphalium lanatum* is diametrically opposed to that of Mr. Robson, for I have always regarded this plant as being most beautiful and effective during the bright and cheerful summer months, with its pretty grey foliage and stems of a peculiarly soft and pleasing hue, but as the autumn advances, and the dulness and moisture of the atmosphere increase, the colour changes till it becomes a kind of dull bluish green.

From a comparison of grey-leaved plants which I have lately made, I find *Centaurea ragusina* retains its clear greyish whiteness just as well towards the end of October as in the midst of summer, with just the slightest tendency in a few of the oldest leaves to become green. Next to this in whiteness is *Cineraria maritima*, but this plant is by no means so effective as the former. *Centaurea gymnocarpa* almost invariably becomes green early in the autumn. The *Cerastiums*, both *Biebersteini* and *tomentosum*, have lost much of the pearly whiteness which renders them so beautiful in summer. *Stachys lanata* is also somewhat dull, and *Salvia argentea* has lost nearly the whole of its true colour, and has assumed that dull green appearance to which all grey-leaved plants have a tendency as the year declines.

As regards dark-foliaged plants, I suppose that for general utility and refined beauty *Coleus Verschaffelti* is by most admitted to take the lead, but even it must give place to *Iresine Herbstii* in the autumnal months; for no sooner does the heat of summer begin to decline than the *Iresine* throws off its summer guise, and assumes a vigour of growth and freshness of appearance most pleasing to look upon. Perhaps this plant is never seen to such advantage as when planted beside *Vinca major elegantissima*. Not only is there a close resemblance in the shape of the foliage of these plants, but also no contrast can be better than the deep crimson of the one with the clear bright yellow of the other.—EDWARD LUCKHURST, *Egerton House Gardens, Kent*.

MANLEY HALL, STRETFORD, MANCHESTER.

THE RESIDENCE OF SAM MENDEL, ESQ.

WE often see the greatest results produced under difficulties, and in positions the most adverse for their successful attainment, but with ample means at disposal, and where judgment and energy are brought to bear upon any given subject, the difficulties which stand in the way are quickly removed, and the path which leads to the successful issue is soon cleared of all obstacles, and the object in view is safely, if not speedily, gained. When, therefore, such a liberal patron of floriculture and horticulture as Mr. Mendel makes up his mind to surround his mansion with the most choice gems to be found in the floral world, it matters not whether the battle-ground chosen be on the Stretford marshes, which are frequently enveloped in the sulphureous smoke from tens of thousands of factory and

other chimneys, and where, as a rule, for many months in the year it rains almost incessantly, he has only to find the means, and give his instructions to skilful horticultural and floricultural generals, and superlative plants are produced. It matters not whether they are natives of the tropics or of the dry hills and plains of the Cape, they are there to be seen in the greatest luxuriance; and it must be very satisfactory to Mr. Mendel to see such results produced, and also very gratifying to his able gardeners, Messrs. Petch and Milford, to find their labours crowned with such success. Not twelve months ago I saw the plants, and certainly a wonderful change for the better is now apparent.

There is no attempt at architectural gardening, but Mr. Edward Milner has very successfully made the most of the ground by a series of happy combinations, which are very cheerful and picturesque, and, in my opinion, very much more pleasing to the eye than so much of the made-up style of gardening seen in many places. The eye becomes wearied by looking from month's end to year's end upon colours artificially produced; but the graceful style of imitating Nature, which Mr. Milner has made peculiarly his own, introduces fresh scenery at every turn, and thus avoids monotony.

Manley Hall is situated on the west side of Manchester, and is about three miles from the Manchester Exchange. The approach to the mansion and gardens is from the Chorlton road, and after passing through a very handsome gateway, by the side of which there is a substantial lodge, we enter upon the carriage drive, which is about 20 feet wide, and on each side of which there is an avenue formed with Lime trees, Hollies, and *Thuja borealis* planted alternately. These are on grass, and at the back of them a low wall covered with Ivy has a very pleasing effect. The carriage drive and all the walks are made with asphalt and gravel, and are kept so clean that anyone might walk over them barefooted without soiling his feet. Directly opposite the entrance gate a portion of St. Mark's College is seen in the distance, with its handsome turrets surrounded by splendid masses of foliage, which are just now assuming their autumnal tints, and between the carriage drive and the College is a beautiful undulating glade, through which the College is seen. The entrance to this glade is concealed from the carriage drive by a group of figures representing Time, and the pedestals on which these figures are placed are clothed with Ivy. At the back of the group there is a semi-circular wall, which is also covered with Ivy, and a little to the right a walk leads to the mansion. The ground on this front has been skilfully laid out to afford undulating scenery. This walk brings us up to the north front of the mansion, which is a very handsome structure, on the south and east side of which there is a terrace raised about 5 feet above the general level of the grounds.

The walk above-mentioned leads round below the terrace wall to the east and south, and past the grand conservatory, which is built at the south-west angle of the mansion. It is a very handsome building, 90 feet by 48, having four half-circular roofs, three of which are parallel with the walk on the south front, and one which covers the principal entrance from the garden, through the conservatory, to the sculpture and picture galleries. There are three flights of steps which lead to three different levels in the conservatory, which is divided into three sections by a walk from the west end under each of the three roofs, and terminating at the top of each flight of steps. At each side of the steps leading through the conservatory there is a pair of *Rhopala corcovadensis* and *Rhopala de Jonghii*. These are handsome trees, 12 or 14 feet high, and form a fine avenue; between them are fine Palms, and costly marble sculpture.

Directly opposite the middle level, and on the right hand side as we go up through the *Rhopala* avenue, there is a pair of doors, which open to the terrace in front of the mansion. The upper portion of the conservatory is parallel with the picture gallery, and is very tastefully laid out as a rockery, and about the centre of this there is a waterfall very skilfully arranged, and here and there, as we traverse this walk towards the west end of the conservatory, we come upon splendid fine-foliaged plants and many Ferns of great beauty. Here were plants of *Dracena latifolia*, with clean stems 10 feet high, and beautiful heads of bright green foliage; and at the base Cyperids, Ferns, and various Mosses grow from amongst the rocks. At the west end of this walk there is a grand *Rhopala de Jonghii*, 18 feet high, and near it we descend by some rustic steps to the second level, or central portion of the conservatory. This walk is 5 feet 9 inches wide, and on each side there is a

curb about 10 inches above the level of the path; on this curb there is a row of shallow pans, 3 inches deep and 9 inches wide, which, being filled with *Selaginella denticulata*, look exceedingly pretty. The borders right and left of the walk are filled with flowering and fine-foliaged plants, among which I noticed splendid plants of *Cycas revoluta*, *Dicksonia antarctica*, *D. fibrosa*, *D. squarrosa*, and several others; *Cyathea dealbata*, *Cibotium princeps*, the beautiful *Cibotium Schiedei*, *Blechnum corcovadense*, with splendid fronds, the youngest of which were nearly scarlet, *Corypha australis*, *Azaleas* and *Camellias* covered with flower buds, and many other fine plants, such as *Dracenas*, *Agave aureo-variegata*, &c. At the east end of the walk we turn to the right, descend another flight of steps, and pass along the walk through the lower level. A stage on the left is filled with *Nosegay Pelargoniums* and yellow and other *Calceolarias*; these were exceedingly gay. The bed on the right was filled with various kinds of ornamental-foliaged plants, and amongst these a number of plants of *Salvia splendens* were very bright. There were also numerous plants of the *Tricolor* and *Bronze* and *Gold Pelargoniums*. The latter Mr. Petch considers invaluable for conservatory decoration in winter. The foliage of many of them was very bright; many, too, were also producing large numbers of very fine flowers.

Just at the termination of this walk, at the west end, on the left-hand side of the door, there is a beautiful aviary filled with birds, which kept up a perpetual chorus all the time I was in the conservatory. Their constant warbling notes mingled with the dripping fountains, the beautiful plants one sees at every turn, and the canopy of graceful climbing plants which here and there covers the roof, rendered the conservatory one of the most charming scenes I have ever witnessed. There one might fancy himself far away in some secluded spot, instead of being within three miles of the busy city of Manchester.

I very reluctantly left this Crystal Palace, which contains so many gems, both of Nature and art, by the door at the west end. Here a flight of three steps brings us down to where a large Peach house is being cleared away to make room for a magnificent fernery, to be built in its place. This fernery will be joined to the conservatory at the west end, and attached to a solid block of houses, which extends more than 300 feet, with a width of 55 or 60 feet, towards the south. The fernery which is now being constructed will be 68 by 28 feet; the conservatory will open into it, and with a little trouble the family will be able to pass from the conservatory through the whole block of houses without going into the open air.

On the west side of the block of plant houses are the bothies, garden offices, workmen's mess rooms, fruit and Mushroom houses, &c., which are very neat and comfortably fitted up, and in front of these is a long border, where Mr. Petch plants out all the evergreens used for the winter decoration of the flower garden.

In passing through the fine block of plant houses, which are all admirably suited for the growth of the various families of plants they contain, I shall give the sizes of the plants in order that all persons interested in the cultivation of the different kinds may know what marvellous specimens those are which I am now about to review, and in how very short a time large specimens of plants many people think very difficult to grow, may be produced, if only placed in suitable houses and a proper amount of care and attention bestowed. In the range to which I now refer, are houses for East Indian and cool Orchids, houses for Palms, houses for Gold and Silver Ferns, a house for the graceful *Gleichenia* family, houses for fine-foliaged greenhouse plants, also for stove plants with ornamental foliage, houses for flowering stove and greenhouse plants, houses for *Ericas* and New Holland plants, houses for *Ixoras*, also for *Marantas*, &c.

The *Maranta* house was the first I entered after passing the site of the new Fern house. This is a fine span-roofed house, with a tank in the centre filled with water. Two 4-inch hot-water pipes pass through the tank, and the noble *Marantas*, *Anthuriums*, *Alocasias*, &c., are placed on pots just above the level of the water. There is a pathway on each side of the tank, and a slate slab forms a shelf next the glass all round the sides of the house. Both the slabs and the ground beneath them are covered with white Derbyshire spar, which gives a very neat finish, and is an excellent material to set the plants upon, as it allows the water to pass freely away from the pots after watering.

On entering the *Maranta* house by the door at the east end, from the walk which runs parallel with the ends of all these houses, the first plant that meets the eye is a noble *Maranta*

Porteana, and next to this, *M. Lindenii*, measuring 1 foot 6 inches in diameter, no doubt the finest plant in the country of this magnificent species. A little to the left of this is a marvellously fine specimen *Anthurium Scherzerianum* (the large-leaved variety), for there are evidently two varieties of this the handsomest of the *Anthuriums*. The plant is making great progress; some of its leaves are 19 inches long by 3½ inches wide, and it had on it during the past summer nineteen splendid spathes all at one time, and there appears to be every likelihood of its producing nearly thirty next year. It is, undoubtedly, one of the finest specimens in cultivation. There is also in the same house another large plant, but it is of the small-leaved variety, and although very beautiful much inferior to the large-leaved one. There is likewise a plant of *Alocasia intermedia*, one of the fine plants sent out this season by Messrs. Veitch, of Chelsea. There are, besides, many other remarkable specimens of leading new stove plants, such as the beautiful *Dracena regina*, *Croton interruptum*, and *C. irregularis*, the handsome *Alocasia Jenningsii*, and *Abutilon Thompsonii*, all distributed to the public this season by the same celebrated firm, whose introductions though expensive may be relied upon, and which always will remain monuments of their enterprise and energy. The next plant I have to describe, is also one of their finest introductions amongst ornamental-foliaged plants. I can just imagine their looks of astonishment, on reading this description, to find that the plant they sold to Mr. Mendel only a few months ago, of *Sanchezia nobilis variegata*, is now 7 feet 6 inches across. There are eighty-four shoots on it clothed with its handsome foliage, and a short time ago it was showing a flower spike at the point of every shoot; these Mr. Petch had all pinched out, and each of the leading shoots is now breaking beautifully. The plant is a perfect pyramid, and as no conception of its beauty can be formed by looking at it from the path, I was tempted, at the risk of pushing my head through the glass above, to get up on the curb of the tank in order to obtain a full view of this noble specimen.

There were also fine plants of *Anthurium magnificum* and *Maranta Veitchii* (there appear to be two varieties of this handsome plant also), and near the fine *Sanchezia* an extraordinary plant of *Alocasia metallica*. This, Mr. Petch told me, was in a 10-inch pot in the spring. It is now 4 feet 6 inches high and 6 feet through; it has upwards of two hundred fully developed leaves in beautiful condition, and is indeed a marvel in plant-growing. The secret seems to consist in growing the plant in a rich compost. The soil it is now growing in is decomposed manure and loam in equal proportions; and as the plant stands over the water there is no chance of its being infested with thrips and red spider, which very often spoil the beauty of this *Alocasia* when it is grown in a dry temperature. Near the last-mentioned specimen is a fine plant of *Maranta roseo-picta*, one of the magnificent introductions of 1866. It is 3 feet 6 inches in diameter and in perfect health. I also noticed fine plants of *Anthurium regale* and *Alocasia macrorhiza variegata*. Trained to the roof of this house containing so many splendid specimens, were healthy plants of *Dipladenia amabilis*, *Cissus discolor*, and various other climbers, which were all perfectly clean and healthy. I must not, however, forget to mention the fine plants of *Fittonia argyrea* 2 feet 6 inches in diameter, and perfect masses of silvery foliage. I also noticed Williams's variety of *Anthurium regale*, which appears to be much the finer of the two varieties of *A. regale*, having longer and larger leaves, of a much darker colour. The pretty *Costus zebrina* also riveted my attention for a moment on leaving the house, and made me almost wish to retrace my steps in order that I might mention many other gems which I had very reluctantly passed by, for time warned me that if I intended to review the contents of between thirty and forty more houses I must be moving, seeing that I had only two short days in which to take my notes, and that the first was fast wearing away.

With this forcible reminder before me, and feeling anxious to do justice to every department, I passed into the Palm stove. Here the plants most remarkable were a splendid *Verschaffeltia splendida*, 7 feet high, with leaves 5 feet long by 3 broad in the widest part; *Pandanus reflexus* (the Screw Pine), 11 feet high, and nearly as many feet in diameter; *Thrinax elegans*, *Stevensonia grandifolia*, *Areca Verschaffeltii*, and *A. crinita*.

The next house I entered is called the *Gymnogramma* house, and a fine sight it is. Here are splendid plants of *Gymnogramma pulchella* 5 feet, and *G. Martensii* 6 feet in diameter. The house is about 30 feet long by 18 wide, and completely

filled with the fine collection of *Gymnogrammas* ever seen, and all of them in the most perfect health and condition. There were in this house many more of the finest *Gymnogrammas* of equal dimensions to those named.

Passing through the house devoted to the *Gymnogrammas*, I entered another of similar dimensions, and, like it, a lean-to. The front slab next to the front lights is covered with fine healthy specimens of *Adiantums* of all the best varieties. There, in great luxuriance, is to be seen the graceful and beautiful *A. farleyense*, undoubtedly the most handsome of this most graceful section; also *A. cardichlamys*, *A. Féei*, *A. scabrum*, *A. reniforme*, *A. pulverulentum*, and many others. In the body of the house there is a pit filled with tan, on which are brought forward many plants for the decoration of the conservatory, such as *Poinsettias*, *Gardenias*, *Azaleas*, *Camellias*, &c., and very conspicuous amongst these I noticed several plants of the old *Azalea caracasensis* with its trusses of bright crimson and golden flowers. It is now very seldom seen, but is one of the most useful plants grown for conservatory decoration in winter; it may also be had in flower nearly the whole of the year, and is a most valuable plant for affording large quantities of cut flowers. It is to be regretted that it is not more extensively grown, which it certainly would be if better known. The rage for beautiful-foliaged plants has of late caused many of our old favourite flowering plants to be forgotten, and their cultivation has in consequence been very much neglected, and in some cases they are completely lost to the country; it is, however, to be hoped that their cultivation will again be resumed, and their beauty and sweetness be again appreciated as they deserve to be.

I next entered the *Gleichenia* house, where, perhaps, the greatest change ever seen in any collection of plants has taken place. They are without doubt the finest set of plants in the world, but when I saw them twelve months ago they were in a sad plight owing to unskilful treatment. Mr. Petch wrote to all the sage Fern-growers asking for advice and assistance, so that he might save these noble plants from destruction, and many suggestions were offered and several kinds of medicine recommended; some advised him to cut them down, others told him to divide and repot them; but after having had so many strange doctrines suggested, none of which he dared act upon, he made up his mind to depend upon his own judgment, which has turned out perfectly safe and satisfactory. At the time Mr. Petch took charge of the plants, not thirteen months ago, they were in a pitiable state, covered with all the pests that plants of this class are subject to, and very soon after they were taken in hand, as stated above, I saw them, and at the time pronounced it a hopeless case; but now, in this short space of time, their restoration to perfect health is almost complete. This result has been brought about by the most careful attention to the following precautions—namely, watering very sparingly, gradually cutting away any decayed fronds, and above all lowering the temperature considerably, instead of stewing them to death in a very hot and humid atmosphere. They were gradually inured to a temperature of 55°, and all the air that could with propriety be given, was admitted on all favourable occasions. This is a hint I think many may profit by. We often see the beautiful *Gleichenias* either being roasted alive or broiled with steam from the hot-water pipes, at the same time rendering the house unfit for any lady or gentleman to enter; but in a moderately dry temperature of 55° one may stay for any length of time to admire the beauty of these graceful plants. The house is span-roofed, about 50 feet long by 22 wide, and there is a large bed in the centre, and slate slabs along the sides. There are three rows of plants on the centre bed, some of them of very extraordinary dimensions. Thus, of three large plants of *G. flabellata*, I measured one just opposite the door, and it was 5 feet high in the centre, and as many feet in diameter. The under side of its handsome foliage was covered with fructification. There are also plants of several other species, as *G. dicarpa* and *G. microphylla*, quite as large, and all in good health; also fine specimens of *Lygodium scandens*, and two very handsome plants of *Davallia dissecta*, about 5 feet high. Two stumps or blocks of wood formed the groundwork of these fine masses, around which the creeping *Davallias* have twined their fronds and shoots in every conceivable form. There was also a balloon-shaped plant of *Lygodium polystachyum*, one of the finest of them all, and three large plants of *Gleichenia spelunca*. Many of the above are in pans from 2 feet 6 inches to 3 feet 6 inches in diameter, and 18 inches deep. There is also a fine healthy plant of *Gleichenia Mendelii*, a silvery *Gleichenia*, with its fronds nearly

as beautiful as *Gymnogramma peruviana*. The sizes of the pans these plants are growing in will give some idea of that of the plants. The side slabs are occupied by younger plants of the above and numerous other Ferns, but it would require more space than could be spared to describe them individually.

Along the back of this house there is a walk, which leads in a direct line from the two lean-to houses previously described to two lean-to vineries. The back wall of the *Gleichenia* house on the farther side of the walk is covered with *Ficus repens* and *F. barbata*, there are also patches of Stag's-horn Fern growing out from amongst the green mass of foliage formed by the *Ficus*, and the latter completely cover the wall and run along a portion of the roof, hanging gracefully over the walk. At the base of the wall there is a pretty mass of rock-work covered with *Lycopods* of various kinds, and dotted here and there with handsome-foliaged *Begonias*, *Tradescantias*, and other suitable plants. This is certainly a most interesting house, and I very much regret my inability to do it the justice it deserves.

Leaving the *Gleichenia* house I passed through two lean-to vineries, the back walls of which are covered with Fig trees. These houses are used more for hardening off plants that have been forced for the conservatory than for the fruit produced in them, for the Grapes, I should think, would not be of very high merit; these vineries will very likely be used as plant houses alone, for other structures more suitable for Grape-growing are provided.

The ground in front of the four lean-to houses, which are situated two on each side of the *Gleichenia* house, is occupied by three Orchid houses and a large span-roof pit, filled with plants suitable for decorative purposes. The contents of the three Orchid houses, with the two magnificent ferneries on the east side of the grounds, must form the subject of another paper.

Excepting in the three Orchid houses, I have now noticed a few of the principal plants in the structures passed through from the conservatory to the second Peach house, which is parallel with the *Gleichenia* house, and between it and the Peach house is the cool Orchid house.

I next entered from the vineries above described what is called the second Peach house; it is a fine span-roofed house 53 feet by 20 feet, with a high roof. The trees are planted at each side, meeting at the centre of the roof, and remarkably well they look. There is now a chance of their doing very much better, for the roots of each set of trees have been hitherto confined in narrow brick pits, but its walls have been removed, and the roots will have much more scope, and with fresh soil the trees may be expected to afford excellent results next year. In this house there is a very useful lot of *Azaleas* well set with flower buds, also a number of finely-ripened Vines in pots, which give promise of producing fine fruit in 1869.

On quitting the Peach house, I passed into the Erica house, which is span-roofed, 69 feet 9 inches long by 15 feet 6 inches wide. It is a very fine house, having a strong stone table all through the centre, with a stone slab on each side; it is well ventilated, indeed a house suitable for the cultivation of Cape Heaths must be provided with the very best appliances for producing a constant circulation of air. This house, more than any other at Manley Hall, shows the triumph of patient persevering skill over difficulties which to many plant-growers would seem insurmountable, for no place could be more unsuitable than the neighbourhood of Manchester for the successful cultivation of Heaths. I will just enumerate a few, and give their sizes, and when I state that they are all in fine health, with nice green foliage, some idea of Mr. Petch's ability as a plant-grower may be formed. A look into this house called to mind the splendid houses of Heaths grown by my friend, Mr. S. Smith, of Lower Norwood, whose magnificent plants were the gems of all our great exhibitions from 1849 to 1854. They also reminded me of the fine collection I myself had charge of some years ago, at the late Mr. Bicknell's, near Camberwell. I had only one fault to find with Mr. Petch's plants, and that was a want of neatness in the mode of training them, the material used for this purpose was rather too clumsy-looking. I remember the time when I was a journeyman, and used to sit up frequently till one o'clock, and even later in the morning, tying the plants I then had the charge of, and not a strip of matting was used; mine were all tied with black thread, so that not a single tie could be seen. I very much hope this beautiful class of plants will again become fashionable.

On entering the house from the west end, the first fine plant on the centre table is *E. æmula*, a noble plant, 4 feet 6 inches

in diameter, and 2 feet 6 inches high, in the most perfect health—it had upwards of a thousand trusses of flowers on it last summer; *E. Irbyana*, 4 feet high, and as many feet in diameter; *E. ventricosa rosea*, 3 feet 9 inches high, and 4 feet in diameter; *E. Parmentieriana rosea*, a splendid plant, 3 feet 6 inches high, by 3 feet 6 inches; *E. conspicua nana*, of similar dimensions; *E. elegans*, a fine plant, in the most robust health; *E. Shannoniæ*, 4 feet, by 3 feet 6 inches; *E. vestita coccinea*, also of similar dimensions; *E. ventricosa magnifica*; *E. retorta major*, 4 feet high by 4 feet, a magnificent plant; *E. Paxtonii*, 3 feet by 5; *E. Hartnelli virens*, 3 feet by 3. There are also two rows of fine half-specimen plants of the following kinds, all in a fine state of health:—*E. Victoria*, 3 feet by 3; *E. ampullacea*, *E. obata*, *E. tricolor Eppsi*, *E. aristata major*, *E. depressa*, *E. Lambertiana*, covered with its pretty wax-like bell-shaped flowers; *E. Massoni major*, a fine plant; *E. Vernonii*, *E. Candolleana*, *E. æmula*, *E. fastigiata*, *E. eximia superba*, *E. metaliflora*, *E. affine*, *E. delicata*, a fine plant, and many others. I also noticed fine plants of *Acrophyllum venosum*, some of which were 3 feet 6 inches high by 3 feet, and very handsome; also handsome plants of *Genetyllis tulipifera*, and on the centre table at the east end, facing the door there is a noble and very handsome plant of *Genetyllis fuchsoides*, 4 feet by 4. On the south side of this house there is a very useful pit filled with *Cyclamens* and other plants.—J. WILLS, F.R.H.S.

(To be continued.)

FIG CULTURE.

WHETHER Fig trees succeed best nailed to a wall or unnailed has, on several occasions, been mooted in your Journal, but we must not allow the case of the nailed trees to be damaged by the results which followed the injudicious pruning noted by your correspondent, "E. L.," in page 316. Of course, "but little fruit was ever ripened" on trees "beautifully trained and most rigorously pruned on the spur system."

Assuming the case of two trees, both properly pruned, one of which is nailed carefully against the wall, and the other allowed to straggle away from it, we may, I think, decide on their respective merits as follows:—The branches in contact with the wall being warmer will start earlier. If, therefore, a severe late frost should occur the fruit is lost, but this may be prevented by covering-up every night until all fear of frost is over. From a tree thus protected I have gathered a ripe Fig on the last day in July. Where it is not convenient to take so much trouble, the straggling tree has the better chance of bearing, but the crop will be rather late.

In comparing the fruitfulness of two trees, observers should take care that the trees are of the same variety. With any other fruit such a caution would be superfluous, but so little attention is paid to the Fig in most gardens, that it is by no means uncalled for. The owner of a Brunswick Fig must not blame his gardener if his tree produces only a tithe of what might be produced on a tree of Brown Turkey.

The account which your correspondent gives of a second crop in the open ground at Provender, is very interesting. The Early White variety, though much cultivated in the last century, is now not often seen. It has given way to the White Marseilles. There is not much difference in their earliness, or in their flavour—perhaps we ought to say their want of flavour; but they are very sweet and pleasant. To any of your readers who may grow Figs under glass, and be desirous of trying a new sort, I recommend *Grosse Verte*, but they must beware of too much moisture either in the air or soil while the fruit is ripening, or it will crack.—G. S.

MYSORE AGRI-HORTICULTURAL SOCIETY.

WE have been asked what vegetable and flower seeds should be taken to India by a lady going thither to become a matron, and the best answer we can give is a list of some of the subjects for which prizes are offered by this Society, for, of course, prizes would not be offered for what cannot be grown in Mysore. The Show is to be held at Bangalore next February.

There are prizes offered for—among fruits, Apples, Peaches, Strawberries, Raspberries, Oranges, Limes, Citrons, Pine Apples, Plums, Grapes, not less than three varieties, and Plantains; among vegetables, for Potatoes, Savoy, Red Cabbage, White Cabbage, Brussels Sprouts, Cauliflowers or Broccoli, Carrots, Turnips, Khol Khol, Beetroot, Lettuce, Endive, Artichokes, Jerusalem Artichokes, Celery, Onions, Vegetable Mar-

rows, Cucumbers, Parsnips, Long Radishes, Turnip Radishes, Dwarf Kidney Beans, Asparagus, Windsor Beans, Peas in shell, Tomatoes, pot herbs—viz., Thyme, Parsley, Mint, Sage, &c., Sweet Potatoes, Capsicums, Nepal Chillies, Pumpkins, Snake-kai, and Brinjals (a kind of Egg-plant—*Solanum*); among *plants and flowers*, for Roses in pots, ornamental-foliaged plants, Asters, Achimenes, Balsams, Caladiums, Carnations, Dahlias, Fuchsias, Gladioli, Gloxinias, Pelargoniums, Ipomæas, Petunias, Portulacas, Phloxes, Salvias, Tropæolums, Verbenas, and double Zinnias.

Let us add for the juncundation of poultry fanciers that prizes are offered also for Game fowls, common fowls, Cochin or other foreign fowls, Ducks, Turkeys, and Geese.

SPURIOUS MELON SEED.

LAST year I ordered from an old-established seed firm a packet of the Malvern Hall Melon seed, but when the fruiting time arrived I found that I had no less than four different sorts from that one packet of seed, not one fruit of which bore the slightest resemblance to the fine variety above named. The truth is, all four fruits (if they may be so called) partook more of Gourds than Melons, both in appearance and in quality.

This year I have been equally unfortunate with that highly extolled new variety called Golden Queen. This I had from a seed firm in the northern part of the kingdom. I had a packet of its seed (that is, if I had the true sort), which contained six seeds, for the small charge of 2s. 6d. The plants have certainly grown luxuriantly enough, but they have persistently refused to show a single female blossom.

Other kinds when the seeds have been sown here, have produced excellent crops, so that there has been nothing wrong in the cultivation of those sorts complained of.

The seeds of this so-called Golden Queen must have been from a fruit not sufficiently ripened. Perhaps some one of your readers may be able to assign some other cause for its unfruitfulness. Those who have grown and fruited the Golden Queen would greatly oblige by saying what they think of it. It might be the means of preventing others from throwing away half-a-crown.—W. H. C., *Maidstone*.

ARRANGING AND PLANTING SHRUBS.

(Continued from page 278.)

PRESUMING the plan of planting to have been decided on, and the outlines of the groups, masses, and borders to have been marked or pegged out, the ground must be prepared for planting. In general, the border should incline from the back to the front, and the groups or masses ought to be higher in the centre than at the sides, next the walk or grass. It is objectionable to have the ground higher next the walk than at back, though this may sometimes occur when the walk is situated at a high level, and the ground slopes from it, for much of the beauty of the shrubs will be hidden, unless there are other points whence the bank can be seen to advantage. If the hollow come directly in the way, we have no alternative but either to go round it, or fill it up, the former being by far the better mode, as the slope, when clothed with shrubs, will have a fine effect on being viewed from the pathway winding at the bottom. With respect to the hollows that occur in groups or borders, they should be levelled to some extent, in order to have a good effect, and flat spaces would often be improved by throwing up a mound. An irregular surface has always a better effect than a flat one, and mounds are very useful to account for the diversion of a path, and these, a group of shrubs, or some other object must give an apparent reason for every turn in the walk.

That all borders and groups should be higher towards the back than in front, whether the incline be only 1 foot in 12, or 1 foot in 3, is an essential to good effect very often overlooked by planters. In some cases we may see the soil from the walks or drives cast out on one or both sides of the walk, without any other care being taken than to raise the ground for a short distance from the edge of the walk, making it higher there than at the point most distant from the walk. Another very common error consists in casting the soil from the walks upon the borders, so that the narrow parts of the border or mass are made higher than its widest parts, for the former, of all others, should be the least in height, being in the case of a flat surface the only places where an attempt at forming a hollow should be made, and if naturally higher than the wide parts they ought to be sunk rather than elevated.

The wider the border the greater should be its incline, and the ground, whether of border, mass, or group, ought to be elevated above the walk. The soil from the walks and drives will go far towards securing the required inclination, and will in most cases be sufficient; besides, it will, by giving greater depth of soil, contribute to the well-doing of the shrubs.

The ground ought not only to be freed of all inequalities which cannot be planted, but the subsoil must be considered. If the subsoil is wet, and water lodges there, to insure the success of the shrubs, it must be properly drained. It is a great mistake to act as if shrubs will grow anywhere; few exist in a bog, and though some succeed in moist ground, none do so where the water becomes stagnant in the soil. The drains ought to be deep, a depth of 4 feet is not too much, and as a matter of course they must have a proper outlet.

The next matter to engage attention will be the soil itself. This must be examined with regard to its suitability for certain plants. If it is not what is required, it must either be improved by incorporating with it a quantity of the proper description, or by replacing it altogether. If the soil is shallow, before planting its depth must be increased; it is well in all cases not to plant in a depth of less than 18 inches of soil without making an effort to secure at least that depth. Soils, however, that are naturally shallow, but have a subsoil which can be easily penetrated by the roots, are very often suitable for planting, more so than deep soils rendered cold and wet from want of draining. The chief objection to shallow soils is that the plants are very liable to suffer from drought, but in general they are dwarfer, and flower and produce berries more profusely than those in deep soils. These, on the contrary, are favourable to growth, and the roots, from penetrating to a greater depth, are better able to cater for the foliage; the plants are, therefore, more abundantly supplied with food, and are better able to resist dry weather than those in shallow soil.

To insure success in planting, and free growth, shallow soil ought to be made as deep as practicable, by trenching it not less than 2 feet deep, putting the top at the bottom, and bringing the bottom to the top, unless the bottom soil is bad; then turn over the soil as deeply as you can without bringing too much of the bad soil to the top, and loosen the bottom. Few on going into a nursery can fail to notice the great difference in the growth of shrubs there as compared with private gardens, making as much progress in nurseries in two years as in other gardens in three or four. Some tell us that it is due to the plants being drawn up by close-planting, and there is certainly some truth in that; but the result is in a still greater measure attributable to the labour expended on the preparation of the ground. Nurserymen invariably, in breaking up land, have it well and deeply trenched. This in my opinion is the one great point of difference, and that by which their shrubs and trees attain such a superiority of growth. It is surprising that those who are proud of fine trees and shrubs, should often be so parsimonious as regards the preparation of the ground for planting. Good plants, well-rooted, carefully planted, and attended to in their early stages, seldom prove satisfactory if the ground has not been properly prepared. The results are as different as light from darkness between planting in trenched ground, and in holes made in little better than a rock, all the feeding ground the plants have being the small quantity of loose soil contained in the holes.

Errors are not confined to the preparation of the ground, but the proper time for planting appears not to be well understood, for planting is generally in full progress in the depth of winter, than which a worse time could not well be. The ground is then wet and cold; the roots, instead of putting forth fresh rootlets, imbibe moisture and begin to decay, and the plants commence the succeeding season of heat and drought with an impaired constitution, without the means of meeting the requirements of the shoots and leaves, except by the emission of fibres from the thick stem-like roots, which is but a slow process. They may not die, but are so enfeebled that it takes years before they assume a respectable appearance.

These remarks apply more particularly to evergreens, which are best planted in October, though planting may be performed with perfect safety in September if the shrubs have completed their growth and the weather is moist. It is the best time in the whole year for planting all evergreens, not excepting Hollies, which, though they may be safely removed in May, are, in the event of a dry hot summer, not capable of making a good growth, while if planted early in autumn they almost invariably make a good start in spring. Rhododendrons and all American shrubs may be safely transplanted at any season, for

it is almost impossible to lift them without a ball; but they never do so well as in September and October. Spring is not so good a period as autumn for removing evergreens, and for this reason the evaporation by the leaves cannot be so well compensated for by artificial watering as by the autumn rains, and the night dews so refreshing to the foliage, and which are much more copious in autumn than in spring; besides, the ground is much warmer, therefore early autumn planting gives a chance of fresh rootlets being formed before winter, and the plants are prepared for, and generally make, a good start in spring. Those planted in spring, on the contrary, are hurried into growth by the increased temperature before they have made great progress in rooting, and the loss by evaporation must be made up by artificial watering.

Winter is not a good season for planting evergreens; they cannot root, and failing to do that, any loss by evaporation must be injurious to the vitality of the shrubs, and the effects will in time be perceptible. Having planted evergreen shrubs at almost all seasons—indeed, in every month in the year, I am convinced that they ought not to be planted from the middle of April to the end of August, and in midwinter from the setting-in of severe frost until it becomes but slight in spring. From planting at those periods the maximum of failures may be anticipated, whilst from plantings in September, October, and November (if mild) the failures are reduced to a minimum. Early in spring is also a good time, but planting should be done before the shrubs have commenced growth, and autumn planting ought not to be practised until the growths are completed and the wood matured.—G. ABBEY.

(To be continued.)

VERTICAL CORDON APPLE TREES VERSUS LATERAL CORDONS.

I HAVE recently been much interested in two rows of Apple trees, planted within a few yards of each other. The piece of ground allotted to them is a parallelogram, 30 yards in length. On its northern side is a brick wall, in front of which is a row of lateral cordon Apple trees on the English Paradise stock, trained to a wire, and planted 6 feet apart, which now, with the exception of two gaps, arising from trees which died of canker, overlap each other, and form a continuous cordon. They have been planted some five or six years, but have not hitherto been productive. They bore more freely the first and second years than since, owing to red spider having most persistently attacked them, and for which on Apple trees in the open air I have as yet found no remedy.

These lateral cordons, 6 feet apart, are of course fifteen in number, thus occupying the front of the border 30 yards in length, or 90 feet. It is strange to find the mind so often unobservant when a picture is made familiar by its being constantly before one's eyes! I had almost daily seen my vertical cordon Apple trees, and yet it never occurred to me till two or three days since to compare them with my lateral cordons as to their difference in productiveness. I confess to having been astonished, as it is probable some of your readers will be, when I state that on the same space of ground a very large increase of fruit-bearing space on the stems of trees may be had by cultivating vertical cordons. It is proved thus:—Fifteen lateral cordon trees, each 6 feet in length, give an aggregate of 90 feet of fruit-bearing space on their stems, while the same number of feet in length will allow of forty-five vertical cordons to be planted 2 feet apart—the proper distance. My cordons are now on an average from 6 to 8 feet in height. I intend them to be kept at a regular height; each tree to be 8 feet high. This will give a bearing space on the stems of the forty-five trees of 360 feet, yet no more ground space will be required. By adding 2 feet to their stature, which may safely be done, you add 90 feet additional, making 450 feet of cordons on a space of ground only admitting of 90 feet by the lateral method.

These upright single cordons require the same culture as the lateral cordons when trained to iron wires, and the same rigid attention must be paid to summer-pinching. There is one great comfort in seeing to them; no stooping is required, and that horrible back ache, so familiar to all who work in their gardens, is avoided.

It must not be thought that no support is required for these very pretty trees. After two or three years they commence to bear profusely, and they will then require support from a neat stake, if wood kyanised or creosoted, or of iron, of the same

height the tree is intended to attain. The iron rod should be the size of an ordinary curtain rod; but it would be as well if the tree were supported with a wooden stake till it had attained some 6 or 7 feet in height.

The preferable kinds of Apples for vertical cordons are sorts that are not too vigorous in their growth, and that are fertile. The following varieties are very eligible:—For dessert—Ashmead's Kernel, Cox's Orange, Duke of Devonshire, Golden Drop (Cox's), Golden Harvey, Margil, Kerry Pippin, Lodgemore Nonpareil, Lord Burghley, Early Nonpareil, Old Nonpareil, White Nonpareil, Mannington's Pearmain, Reinette Van Mons, Pitmaston Pine Apple, Stamford Pippin, Pearson's Plate, Keddlestone Pippin, and many others of the same habit. For the kitchen the following sorts are not too gross in their habit for vertical cordons, and are for the most part very fertile:—Eddwin, Baron Ward, Cox's Pomona, Dumetow's Seedling, Duchess of Oldenburg, Betty Geeson, Winter Hawthornden, Lord Suffield, Rymer, Small's Admirable, Keswick Codlin, Tower of Glammis, Hawthornden, Jolly Beggar, Fearn's Pippin, Winter Pearmain, and some others. These should all be grafted or budded on the English Paradise stock, as the French Paradise is too feeble in its habit to form vertical cordons.

I have only to add that those who wish to plant vertical cordon trees on the proper kind of stock, should at once select trees only one year old from the bud or graft, budded trees to be preferred. They may be bought at a reasonable price, say at 50s. per hundred wholesale, so that neighbours should club together. No preparation is required in planting them; no posts and wires; the planter has merely to plant his young vertical cordons in rows 2 feet apart, and wait till the summer brings on the pleasant pastime of watching the young shoots and pinching them in to two or three leaves—an operation which should be performed once a-week from early in June till the end of August.

I ought also to mention one operation often necessary, if the trees are inclined to grow too vigorously, so as not to form blossom buds—two strong spades, one on each side, should be thrust under their roots and the trees gently heaved, so as to loosen them, and then replaced and the earth trodden firmly down. In writing as above, I have no wish to repudiate lateral cordons, which may often be employed for edgings to borders with advantage; but I wish to point out how a small space appropriated to fruit culture may be economically used. In a crowded city, where ground space is confined, tall houses are built; there is always room upwards, and so it is with vertical cordons.—T. R.

LLANDUDNO CHILDREN'S FLORAL SOCIETY.

On the 13th October, an important ceremony took place at Tebed Bryn Maenol, small in its beginning, but we hope pregnant with great results.

W. F. Chapman, Esq., of Tebed Bryn Maenol, distributed gratuitously to those children who felt a pleasure in flowers nearly fifty cuttings of the Tom Thumb Pelargonium as a beginning. The recipients consisted of boys and girls from nine to fourteen years of age. A nice potful of mould with the plant in it was given also to each, accompanied with a bag in which was enclosed a bun and fruit. These plants were taken away by the children to be nurtured and trained. They are to be brought back in twelve months time or earlier, as may be decided, when they will all be exhibited, and prizes will be awarded to the best. Such care as will be necessary to train the plants cannot be unproductive of good. It will teach the little gardeners to know that their humble plants have wants, and require watching as well as they do themselves, and through these children perhaps, we may hope, a lesson will be taught to many an indifferent parent. If it do no other good it will perhaps tempt the children to read some of the cheap handbooks on horticulture, and so lead them afterwards to higher tastes and efforts.

Mr. Chapman addressed the children, but we can find space for only a short extract from his address:—“None but the lovers of flowers can form an idea of the interest which is created and grows upon those who begin in their childhood to be gardeners, and who are fortunate enough to have parents who possess a gardener (if ever so small a garden) that understands its cultivation. My parents, also Mrs. Chapman's, were all fond of their gardens, and consequently when we were very little children we were induced to take as much interest in flowers as our parents did, and I am happy to say Mrs. Chapman may truly be called, as the old song says ‘The Horticultural Wife,’ for she works, and takes as much interest in our garden as I do, and I am pleased to say she is not the only lady in Llandudno who is a great gardener, and a working gardener too, for my two good neighbours, now present, take great interest in their gardens, and the establishment of this Society, to which they have promised their sap-

port. To show you, young people, what the cultivation of a flower may do, I will have read to you by one of the young florists, an article from that interesting periodical the 'British Workman,' of May 1st. It will show you the effect which the cultivation of a single flower had on the man who was an infidel. (A little girl named Grey was here called upon to read the story of Charney and the prison flower, which she did in a clear and distinct voice). Mr. Chapman continued—It is not only the gratifying of our sight, but flowers are valuable and useful as medicines. What too, can be more pleasing to an invalid, confined to a bed of sickness, than to have a few sweet flowers to look at?—(*Leeds Register*.)

GARDENERS' TROUBLES.

"You talk about a gardener's life, Will," said Sir Simon Shirley's head gardener to his brother, who was on a visit to him, "and think it free from cares and annoyances. Why the fact is, it is full of them, they spring up thick and fast as weeds in a rainy season. I wish I had been anything else; it is nothing but work, work, from Sunday morning to Saturday night, and however much you may have done, there is always something undone which leaves an uneasy dissatisfied feeling on the mind."

"But, then, Charles, it is pleasant work, the blue sky above you, and Nature, with her freshness and her beauty, all around you."

"That is the mere outside of the matter, the bit of poetry not yet driven away from our much too-practical times. Yet I say nothing against the work, or the pleasure of it. I suppose a man thinks it so, or he would not take to it, though if he choose to dwell upon it, there is a large amount of discomfort, of wear and tear both of body and mind, and more worry than he is always able to endure; for, whatever people may say about the seasons, a gardener has often to fight against them, instead of work with them."

"But it has a refining, elevating, and beneficial influence."

"Not much elevation or refinement possible, in the plodding unsatisfactory lives many gardeners are compelled by circumstances to lead. And as for beneficial influences—physical, I think you mean—there's not overmuch of that, for he is necessarily exposed to all the changes of the weather. It is all very well for a master to say 'How delightful the soil smells during the rain!' but a man loses the delight of the smell when he is out working in it for hours; and there is not much good to be derived from the raking away of mouldy leaves, though when the wind moves them as they are rolled over-and-over, they do bring too many ears whisperings of the sea, like the breaking of waves on a sandy shore."

"Come now, Charles, you must acknowledge to a strong man most of the labour is light."

"Well, so it may be in a measure—but what of mowing by scythe or machine on a wet day, with your boots turned into bathhouses, or digging through 2 or 3 inches of frozen soil, or weeding with the full sunshine on your back, in such a summer as this last, when your clothes, if not your life, proved a burden; or waking up at midnight to rush through the blinding snow across a field, or garden, or, as I have known it, up a pretty long lane, to make sure the stove fire was burning? Ah! Will, these stove-fires are the very nightmare of a gardener's dreams; they will not always do as you want them, and if they die-out it is sure to be when you need them most. When the air is dry and balmy, and you would have them just sleep and no more, they are sure to be roused up by a brisk wind and burn away like mad; and your employer raps his pocket and calls it 'wilful waste,' and goes away quite sure in his own mind there is always such a useless fire. Believe me, a gardener has generally his full share of work, and more than his share of worry. His holidays, few and short as they are forced to be by the very nature of things, have all the sweetness eaten out of them by the dread that in his absence some iron or other will burn in the fire from want of tending. And then there is a feeling of being always behindhand, dragging ever at the heels of things, never able to get up to the work you desire should be done at a certain time—perhaps sowing to-day seeds of plants that should have been planted out yesterday, or thinning coloured Grapes, or finding the summer half over before the bedding plants are out. And even when they are out, and you think the worst is past, and a quiet breathing time come, lots will die off and leave ugly gaps, more than your reserve plants can fill up, and you lie awake many a night wondering where you can pick up a few to supply their places. You have no idea, Will, the trouble bedding plants are, when the sources of supply are too scanty for the demand, and it is

very seldom they are not; for the perpetual cry of our gardens is 'more, more.' To answer this cry a man has to use all his wits, and to work on under disadvantages in many an unacknowledged way, and to fight against difficulties few masters could understand if they were explained to them, and all with nothing to look forward to in the end, as I heard an old Scotch gardener say the other day, 'but rheumatism and a bent back!'"

"But, surely, Charles, times must be easier with you now."

"Only the other side of the picture, less digging, more care, and I am not sure which is the heavier in the long run. I used to think when I was a boy, that when I became head gardener, things would go smoothly with me; a bed of Roses to lie on, no crumpled leaf in it to disturb my happiness. I assure you the Apple is not quite so sweet to the taste as it appeared when out of reach."

"I always considered it a life free from vexation."

"No doubt most men who live out their lives within brick walls do, gathering fruits and flowers on a sunny day; it is only gardeners, Will, who remember rainy weather, east winds, and biting frosts, for they must work on less or more let the weather be what it may. Now of all things grown, none are the cause of more anxiety than vegetables. They are always poor either in quantity or quality. Master grumbles, cook grumbles; in many places they are the killing straw on the camel's back. Fruit and flowers with few exceptions pass from the grower's presence into the master's; there is no half-way house to loiter in and so come to grief; but vegetables, why there is not one grown which may not be spoiled in its journey from the garden to the dining-table. You can guess where the blame falls. I have known Celery be dressed long before it was wanted, and left soaking and losing its nut-like sweetness in questionable water for hours; and young early Peas which had given a world of care and trouble, tossed violently into foaming boiling water until every Pea lost shape and form, and the costly dainty became nothing but an unsightly mess. It is common enough, too, to see fresh crisp Lettuce left in the sunshine or exposed to the kitchen fire until every leaf is like a piece of unstarched muslin. Then most masters have their whims and fancies, which it is not always possible to realise, yet they are quite sure if they were gardeners they could bring about the desired end. There is the Squire at Castlestead, he is always out of sorts if he sees a Camellia in bloom before or after his own, he says there is nothing else worth growing under glass; yet he allows the same Camellias no peace all the season through. Flowers, and buds, and young growth are cut away without mercy, as though they were of no more value than summer Roses. Last winter his man told me that in a short space of time he cut more than two hundred blooms; and then when the flowering was over, and the plants were put to make growth ready for another cutting, the Squire declared his gardener's treatment must be wrong, for the Camellias grew less and less every year, and they were like none he had ever seen before. Things were not so bad before the Squire took a new wife, then flowers were cut without sense or reason, and there was a pair of sharp eyes following the men up and down and everywhere, and sending them to do this, and that, and the other. I have known her have three men running after her, and their real work standing undone the while, and some one not forgetting at the end of the week that much less was done than was expected."

"Ah! Then it is not all sunshine I see, Charles."

"No, I could tell you of many things apparently of little importance, which feed the fire of discontent and take the strength out of a man's arm, the willingness out of his heart. There is Mr. Norton, of Westfield, he considers it lost money to buy flower pots; quite a dreadful affair. He bought some several years ago, and thinks they should last for ever; there is no need they should ever be broken; and he walks about and picks up any stray bits of crocks, and puts them together with the air of a man who is afraid his pots are broken up for crocks. Then there is his brother Mr. Henry, passionately fond of Cinerarias and other greedy plants, yet he cannot bear to see dead leaves and rubbish rotting under a wall, why cannot it be carted into the field at once and done with? And there is Mr. Garnet on the hill, he is always in a fever of disappointment about his Fuchsias; he used to have great, round, splendid plants flowering in a new viney, they were indeed a sight to see, but when the Vines took full possession of the house, and curtained over the windows, taking all the sunshine to themselves and nearly all the light, the Fuchsias dwindled away, grew out in long soft slender shoots, with here and there a bud that never opened its petals. The man did what he

could for them to no purpose, yet all the arguments in the world could not convince his master of the impossibility of flowering them in a shady place. Then there is Sir Simon here, he thinks rather too much about his plants, for nearly every day he goes round the houses looking over his plants and counting them up, and saying, 'I cannot tell how it is, Charles, but some or others of your plants always look as if they were doing nothing. And what has become of the White Camellia I bought last year? And where is that *Tetradlea verticillata* my wife admires so much, with its flax-like flowers? And what is the matter with these Azaleas, are you going to let them die? Or so and so are poor miserable objects, I would turn them out?' But it is of no use, Will, bothering you with troubles you cannot understand, little things not worth noticing, yet many a night when I look up, I think I will look out for keys that turn more easily. Still, somehow or other, a gardener becomes attached to the shrubs and plants he has cultivated, and the old Chestnut tree that has shaded him from the summer heat, though it be poor and thin of foliage, he likes better than any other. So he works on trying to make the best of his circumstances."

"It appears, Charles, that all conditions of life have their dark side."

"Yes, but after all, a gardener, if he is wise, keeps the dark one to himself and a bright one turned ever to face the world."
—MAYN.

RESULTS FROM THE PAST SUMMER.

I wish to record some of my own experience during the past season.

Beginning with scarlet Pelargoniums, among all that I could enumerate none has done better service than Tom Thumb. In large beds it has made a fine display. Planted out early in May in deep well-prepared beds, and with no water afterwards, the plants grew well, filled the beds early in the season, and were a mass of bloom throughout the dry weather until the frost in October put an end to them. There are many useful scarlet Pelargoniums for bedding purposes, but I like Tom Thumb the best.

Yellow Calceolarias that have become so unmanageable on account of the disease to which they are subject, have done well with us, and others in this neighbourhood. They have been free both from the disease and aphids. In my own case I attribute their success to deep cultivation and a cool bottom. If we can keep the Calceolaria free from enemies, I can find no yellow bedding plant to equal it in effect. Though there are in cultivation many other yellow-flowered plants good in their way, I am inclined to believe we shall be some time ere we meet with a better subject in skilful hands than Calceolaria Aurea floribunda. Amongst the crimson varieties, I have met with nothing to equal Victor Emmanuel when well grown; it is just as effective in its colour as Aurea floribunda. I like decided colours.

Centaurea candidissima during the past season has been one of the most effective white-foliaged bedding plants I have had, and it stands very high in my estimation for all decorative purposes. The late dry season has brought the white-foliaged plants to perfection.

Lobelia Paxtonii has been a gem this season, as well as many others too numerous to mention. Gold-edged Pelargoniums have done us good service this season, and are worthy of more extensive cultivation. One of the most useful plants we have grown is *Oxalis tropaeoloides*, producing a pleasing combination with almost any colour. It is of very dwarf habit and an annual, and may either be raised in pots or sown where it is intended to remain. It is a very desirable plant for dwarf edgings either for beds or borders. In white-edged Pelargoniums, Bijou has the preference with me; we have had nothing which could compare with it this season. Planted out in May, and receiving no water but that which the plants had from the heavens, they have far surpassed my expectation, putting Flower of the Day and many others quite in the shade. Brewer's Silver-edged and Mangles's are very useful for covering large spaces.

In the Tricolor class of Pelargoniums, Mrs. Pollock and Sunset have outshone all others. Many who have seen them in masses and in contrast have exclaimed, "We have not many to beat them yet." They produce a fine effect with *Perilla nankinensis* and blue Lobelia. Burning Bush has been remarkably fine, and others of the same strain are very useful in many respects for contrast. Being of slow growth, they require planting thickly to make them effective.

Tagetes pumila is very useful, and has been very fine with

us, no doubt owing to the heat and drought. *Brachycoma iberidifolia* has done well as a blue bedding plant; it may either be prepared in pots or sown where it is to remain, it has done well in both ways. *Phlox Drummondii*, both selected and mixed, has been very fine. *Atriplex hortensis rubra* has answered well for bedding where kept pegged down and pinched. It makes a good contrast with many other plants; but I have not as yet met with a plant of its class to equal for all purposes *Perilla nankinensis* in our exposed and windy locality. Beet, that we hear so much about for decorative purposes, I have not tried. Here I must confess that a prejudice against it has taken possession of my mind. I like to see good Beet in the kitchen garden, and hope to grow it there for some time.

Fine-foliaged plants, such as *Coleus*, *Amaranthus*, and other tender subjects for flower-garden decoration, will not bear our northern climate; therefore we are obliged to content ourselves with those of more robust constitution.

Ageratums, *Heliotropes*, Variegated *Alyssums* and *Arabis*, *Fuchsias*, *Salvias*, and many others have done us good service. *Verbenas*, considering the season, have been very fine, and none has been more prominent than Foxhunter, Mrs. Holford, and Purple King.

Viola montana has done well, but its undecided colour is a great drawback. If it could be improved in colour and the lower petal obtained like the upper petals, I should like it much better. My opinion of it at present is, that it is a good ribbon plant which wants to be seen at a short distance, and contrasted with other plants of opposite colours; then it will pass muster. It is a free-growing and free-flowering plant, and continues long in flower, but will not bear close inspection. I think the herbaceous border or rockery is the best place for it.

Viola lutea has done well, but at best it is but a moderate plant for flower-garden purposes—it looks common. Perhaps this may arise from seeing its type so plentiful in many corn fields. I like it best on the rockery.

Bellis aeneobifolia is very fine in a damp bed or border, but it cannot bear drought. *Bambusa Fortunei* is rather pretty for dwarf edgings. *Lactylis glomerata variegata* is a plant that appears to do well in almost any situation, and is very effective. *Poa trivialis variegata* has not succeeded so well as I could have wished. Perhaps the season has had some effect on it. Golden Feather *Pyrethrum* is a very effective plant for bedding, or as an edging, doing good service everywhere. *Lamium aureum* I think will prove useful for bedding, but I have not had sufficient experience to speak of its merits as yet. *Lonicera aureo-reticulata* trained as an edging is very fine, and ought to be more frequently met with than it is at present, especially in exposed situations. Some of the variegated *Ivies* are well adapted for the same purpose.

I do not know whether the variegated variety of the common Thyme is used much as an edging plant, but I am of opinion that it might prove very effective in many places, being of easy culture. It might vie with many plants at present in use. I find it very useful. Its hardiness is one of its chief recommendations. *Farfugium grande* does well in moist sheltered situations. *Polemonium caruleum variegatum* is really a first-rate plant for decorative purposes, and is worthy of very extensive cultivation, being hardy. When better known I have no doubt it will become a general favourite. *Portulacas* have been remarkably fine with us this season. Beautiful as they all are, I give the preference to *P. Thellusoni*. They do well in light sandy soil, and may be raised in pots or sown early in summer where they are to remain. The *Cupreas* are plants that succeed well here and resist the weather well. *Nierembergia gracilis* makes a good edging and does well with us.—
M. H., Acklam Hall, Middlesborough-on-Tees.

POMOLOGICAL GLEANINGS.

WE have received a SEEDLING APPLE from Mr. William Paul, raised from the Fair Maid of Taunton fertilised with Broughton. It is far larger than either of its parents, and, judging from the specimen sent, is of the size and shape of a large lemon, having the same swelling at the stalk as that fruit; but the colour is entirely of a beautiful pale salmon streaked all over longitudinally with broad lines and broken streaks of deep crimson. The eye is small and slightly sunk. The flesh yellowish, tender, juicy, sweet, and well-flavoured. It is a handsome fruit, and would be highly ornamental in a dessert.

—MR. WELLS, of Southend, has sent us a fine Black Hamburgh Vine in a pot, the cane of which is 7 feet long, and bearing nine large bunches. This Vine was grown in one of the

ground vineries, and a 7-foot length of it was layered in a pot, where it rooted, and when it had established itself it was severed from the parent Vine and became an independent plant, which, when coiled round a few short sticks, formed a handsome pot Vine.

— A MINIATURE CHERRY tree, growing from 10 inches to 3 feet high, with a round, globular head, as hardy as an Oak tree, and bearing large crops of very sweet Cherries, is indigenous in Utah.

— A SMOOTH-LEAVED Cayenne Pine Apple was grown at Colston Bassett, Bingham, Notts, and was cut on the 16th of October, the height of the fruit, including the crown, being 21 inches. The fruit was 21 inches in circumference, its height 12 inches; it was 10 pips deep, and the weight was 10½ lbs. Mr. Lamb is gardener there.

— ERROR.—At page 281, column 2, line 13 from the top for "1300 from a two-year old bush," read "twelve-year old."

WORK FOR THE WEEK.

KITCHEN GARDEN.

ALL that is to be thought of under this head is to see that young *Lettuces*, *Cauliflowers*, *Endive*, &c., are well provided for against the winter. Remove all decaying and damaged *Carrots*, &c., from the root house or shed. Prepare suitable places for a supply of *Turnips*, *Celery*, &c., being stored up on the first approach of severe weather. *Potatoes*, if kept in a house, and especially if taken up in a rather wet state, should have flues formed of faggots passing through the heaps. When sufficiently dried, the draught of air may be stopped or regulated at will. When the flavour of newly-raised *Potatoes* is preferred to having them like balls of flour, a quantity of earth, neither dry nor wet, may be sprinkled amongst them. With a little attention they may be kept as well in a house as by any other method, and any labour they require in the spring and summer can be performed in unfavourable weather.

FRUIT GARDEN.

After this time never lose an hour in which nailing can be done, and never keep men at such work in cold weather. The present changeable weather will furnish an opportunity of examining and removing all decaying fruit in the fruit room. Those slightly specked should be taken out of the fruit room and reserved for present kitchen use, as otherwise the atmosphere of the room would become so tainted as to hasten the decomposition of all the stock. Most gardeners are perfectly aware of the importance of a close atmosphere, and an equable rather low temperature for the long preservation of Apples and Pears. Where, therefore, the fruit room must still be used as a general receptacle, and where, consequently, air will be frequently admitted, the fruit may be covered with clean wheat straw, which will have a tendency to keep it at a uniform temperature, and prevent its shrivelling by perspiration. It is more necessary to attend to this in the present season, as many of our best fruits are fit for table much earlier than usual. The best-keeping Apples and Pears may be packed in jars or new garden pots, covering each layer with dry sand. Chaff should scarcely ever be used for such a purpose, as, however well dried, the moisture from the fruit is apt to make it ferment and vitiate the flavour. Chestnuts, Walnuts, and Filberts are clearer in the shells, and fresher and moister in the kernels when packed in sand than by any other method. *Walnuts*, if previously well dried in the sun, may be kept in a heap covered with straw, provided they be turned frequently, but the kernel is more shrivelled, and the inner pellicle adheres to it more firmly, than when the fruit is packed in sand. The boxes or pots in which it is packed in sand should not be too large. If kept on shelves or in heaps, unless in a very dry place, the outside shell soon contracts a mouldiness, which, if not removed, will find its way to the inside. A quick method of effecting this is to put a quantity of the nuts in a clean sack, and move them backwards and forwards quickly by two men, each holding the two corners of the ends of the bag.

FLOWER GARDEN.

In some places as soon as the frost destroys the appearance of a bed, the plants are pulled up and the ground smoothed over with a rake; it is then planted with the branches of different evergreen trees and shrubs, trimmed up to the shape of little shrubs from 1 to 3 feet high, with stems long enough to be firmly fixed in the soil. They will thus remain quite green till March, and no one can tell whether they are not shrubs turned out of pots on purpose. Branches of *Laurus*-

tinus will flower all the winter in this way, as well as if left on the parent plant. With these, and others of variegated *Hollies*, with the berries on, also pieces of *Arbutus*, various kinds of *Crataegus*, &c., with the fruit, one might make a gay bed opposite a sitting-room window all the winter. *Pinetums* might thus be formed in miniature, and it is likewise a good way to try the effects of planting the different kinds of evergreens in a shrubbery or winter garden. Early-flowering shrubs may be planted along with the above, also spring bulbs, and the shelter of the green boughs will nurse these things from the cold. Sweep as much as you will, you cannot clear up till the leaves are all down. Planting and transplanting trees and shrubs, making and altering walks, and all kinds of alterations and improvements will now and for awhile occupy the time that used to be devoted to flowers in this garden; but amidst all this bustle do not neglect to make the best use of all the leaves and stems, and as much other refuse as you can gather together; and the rougher materials of prunings, old stakes, &c., burn the first fine frosty morning.

GREENHOUSE AND CONSERVATORY.

Chrysanthemums, *Cinerarias*, and *Salvias* are the leading plants that flower just now among the more hardy kinds. *Hedychiums*, *Vineas*, *Clerodendrons*, and *Lantanas* are just over, and are removed to the stove, the first to be dried, and the other three to be shaken out of the pots, put into small ones, and pruned rather closely. This is hard treatment, which would ruin some plants, but they will bear it. *Justicias*, *Eranthemums*, and *Aphelandras*, with *Gesnera zebrina* and *Cactus truncatus*, will take their place. Large specimens of *Crowea saligna*, *Luculia gratissima*, and even the old *Coronilla glauca* make a good mixture with *Chrysanthemums*. The *Luculia*, *Gesnera zebrina*, and *Cactus truncatus* are the best of these for placing in rooms. The old scarlet *Achimenes* can be had in flower later than any of the new ones, and as early in summer. In order to have them in flower to the end of this month, it is best to allow them to push in a cool place early in summer, then plant them out in sandy peat in a cool house on a front shelf or stage, and from this situation they are potted from August to the end of September, and encouraged by giving them a little heat as they are wanted. The whole family is well suited for rooms. The greenhouse must always be kept well ventilated, and especially during the present month. On that account the plants will require to be looked over often, to see that none suffer from want of water. Where there are good cold pits, *Heaths* and many other plants are much better in them than in the greenhouse until the weather becomes severe; indeed, when so much attention is paid to forming all good plants into fine specimens, small plants ought to be kept in frames, if only to have them out of sight, as such plants are of little interest to any one except to the person who must provide for them, however necessary they may be to keep up a collection. In that case specimen plants will have more freedom, and not half the watering will be needed in the greenhouse, consequently there will be less chance of dampness among the plants.

PITS AND FRAMES.

In the forcing pit mild moist spring weather should prevail. Those plants in bottom heat should have it regularly. Tan, leaves, &c., are troublesome as compared to the steady bottom heat afforded by hot water. A moist atmosphere is always congenial to forced plants, and the more hardy they are the more they stand in need of the syringe. Insects should be destroyed as soon as they appear, and let everything be kept clean and sweet. *Cyclamens* that have made good roots will stand forcing for a short time, and will soon throw up their blooms, but like bulbs of all sorts, they are injured by forcing before they have made roots. Indiscriminate watering must be avoided in the treatment of the stock in cold pits and frames. Well-matured plants with no stagnant water around the roots will resist a degree of frost that would be immediate death to others of the same sort that are succulent, of immature growth, and saturated with moisture. *Hyacinths* may still be planted in pots and put into glasses, and those which have been brought forward according to previous directions, may be forwarded in heat if required for early bloom. They can also be grown and bloomed well in pots of moss kept moist.—W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

Celery.—Took the opportunity of earthing the main crops pretty well up, the soil a few inches from the surface being in

good condition as regards dryness, whilst after the rains of last week the trenches were sufficiently wet to keep the roots moist for the season. All the evaporation from the foliage in fine, sunny days now, will be sufficiently counterbalanced by dew and damp days. When the usual mode of earthing-up has to be resorted to, it is as important to have the soil used for earthing-up dry, as to have a sufficiency of moisture at the roots. We took no other precaution in earthing-up, except to have a thin layer of coal ashes round each stem in the beds, each bed being 4 feet wide, and having three rows in that width. Besides the Celery used previously, it has been taken up freely for the last ten weeks, and not a bad or bolted head has been met with. We seldom could have said the same when we used to grow huge, massive heads, or when the bit-by-bit earthing-up system was resorted to in July and August, or even the early part of September.

Lettuces.—Tied these up where they were not blanching enough for use. We have some so placed that we can protect them in bad weather. Those planted out, small, stubby plants, are now standing well, as the grubs seem to have been nearly all taken, after doing the mischief. No other cure seems to be effectual, but examining the earth at every drooping plant, destroying the enemy, and filling up the vacancy again. At the foot of a south wall we turned up what would have been the walking room for 4 feet in width, and planted with young Lettuces, and not one was touched, whilst during the summer and autumn we could not obtain anything like a crop on the raised banks between the Celery beds. The very depth of the soil there, and that on the surface coming from a good depth, one would have thought would have been a security, but there, of all other places, the grubs were the worst. From 100 feet of a row of Lettuces, nearly a pint of grubs has been collected. We have seen very few lately. Had there seemed to be plenty left, we should have used lime and tar water, and even a little tar on the ground most infested. Nothing will grow in tar, or on it, when it is fresh, but used in small quantities at this season, just dropping a little over the ground, it becomes carbonised and mild enough before the spring.

Endive.—We have not yet taken any up, as room is scarce, and the largest and best plants have not suffered from frost in the least. Tied up some fine plants, laid tiles, slates, and boards on others. Where there is a good bed, and it is wanted for use in from a fortnight to a month, and the surface of the ground is moderately dry, nothing answers better than covering the plants over with 2 or 3 inches of dry tree leaves, and then covering these with tarpaulin, mats, or wooden shutters, to keep wet out. We have never had Endive finer and sweeter than when taken up with good balls, and stored in beds in dry cellars. If tolerably dark nothing more was wanted. If not dark, a cloth placed over a piece soon blanched it enough. We have had it in cellars from November to March.

Chicory.—We have none this season, though it is always advisable to have a few rows, as in a severe winter it comes in useful, though not equal in our opinion to Lettuces or Endive. It does well in a dark cellar, or anywhere, when wanted quickly, where darkness and a heat of from 55° to 60° can be given to it. We allude to it, to meet the wishes of a correspondent, who has a nice bed of roots, thinned out 4 inches apart in summer, admires it as used by our French neighbours in winter, and wishes to know if he could not have it from the open ground in winter without any artificial heat, if not how could he have some, with merely the help of some 12-inch pots, and some small oyster barrels? With no heat out of doors, his pots and barrels would be of little use there. If he could make a small hotbed—say 4 feet square, fill a space of 2 feet square rather thickly with roots, and cover that over with a packing box, &c., of that size, he might have fine gatherings of Chicory leaves, and by the same plan he might have Sea-kale and Rhubarb. But supposing him to have nothing but a spare corner near the kitchen fireplace, he may have a good supply from his pots. We would have no objection to the oyster barrels, only they crack at the joints when in a dry place, and let in light.

Proceed thus: Take up and put from a dozen to eighteen roots, according to their size, in a 12-inch pot, putting the roots firmly in the earth, and leaving just the buds of the plants exposed, after removing all the leaves except a few little ones, if there are any in the centre. Water well and leave the pots outside to let all extra moisture drain away, so as not to make the fireside dirty, then move the pot in where it will have the benefit of a little warmth from the fire. Place another pot of the same size on the top of that, fitted rim to rim, cork the

hole in the bottom of the reversed upper pot, and tie a piece of cloth round where the two rims meet, and in the heat of most kitchens the Chicory will be fit to cut in a fortnight or three weeks. A number of pots might be so filled, and kept in a wood barn or coal house until wanted to be brought in in succession. Had our correspondent told us he had a cellar which was dark and would average 50° in winter, then we would have advised using the small oyster or other narrow barrels, boring holes in the sides of the barrel—say half an inch in diameter, and in rows 3 inches apart, the rows round being 4 inches from each other. Place the roots inside in layers with the heads or buds outside the barrel, putting the earth to each layer, firming it, and moistening as you proceed. A few barrels would yield a good succession, and as one is beginning to come into use, a second should be introduced. In a dark place with a temperature of about 50°, we used to have the leaves of a fine creamy white, and from 6 to 7 inches long, in from three weeks to a month. An old worn-out narrow barrel looks very pretty when thus adorned outside with these blanched leaves. The Chicory will be all the better if the leaves are never more than 6 inches long. When long and flabby they eat woolly, and have none of the crispness they have when grown in a low temperature and under rather than above 6 inches long. If prevented becoming too wet, or much frozen, such barrels, planted in layers as above stated, might stand out of doors until wanted to go into the cellar. In all such cases the leaves are chiefly produced at the expense of the materials stored up in the roots. We have already detailed how a friend of ours used to delight many an invalid in winter, by taking a few stalks of Rhubarb which he brought on in barrels in his kitchen. We have sometimes kept our eye on places where *Dandelions* were plentiful by the sides of roads. They are not so strong, but they make a good substitute for Chicory, and the good properties are even rather more strong and active than in the latter. Both may be used with good results for salads, and are especially useful when anything better is scarce.

Kidney Beans.—Those out of doors are quite destroyed, and but few more Scarlet Runners will be obtained, though these are not so much injured; and Vegetable Marrows, which a fortnight ago were showing plenty of young fruit, are now nothing but skeletons, and black leaves, and decaying stems. We have instanced the Dwarf Kidney Beans for chronicling a disappointment which may be useful to others. We are not admirers of Fulmer's Forcing Bean, but having it by us, and others more approved not being at hand, we sowed some in the earth in a pit where just a little artificial heat can be given. We expected them to be fit to gather in the first week in November, but, unfortunately, the plants were not stopped until a week or so ago, and they have grown strong and lengthy, with numerous buds at the joints, but they are just coming into bloom now. Others of the same kind, sown in pots out of doors a month later, and put under glass when a few inches high, as the nights became wet and cold, are also coming freely into bloom, though not nearly so strong and high as the first named, but these had the points of the shoots nipped out at the third joint. Had we done so with those planted we should have had Beans instead of blossoms now. With all the stronger-growing kinds under glass it is advisable to nip out the point of the shoot when it has made two or three joints above the seed leaves. We have had fine crops of the White Canterbury, naturally inclined to run a little, from plants not more than 9 inches above the pot, but they were stopped early. When grown in pots the weaker-growing may be retarded fruiting a few days by stopping them, but they produce more freely and are kept nearer the pot. Strong-growing kinds keep growing on and do not even bloom so soon as when stopped early. The stopping arrests mere growth, and the flower buds swell and open freely. We have frequently noted results as stated above. The first planted had the best treatment all along, and instead of being three weeks or so earlier, they will come in little earlier than the second. Through a slight change of circumstances it will turn out quite as well, or rather better for us, but that will be more owing to chance than to management or design.

Mushrooms.—Put a little more dry litter over the Mushroom beds in the open thatched shed, to keep them on, as we do not expect to gather from the first piece in the Mushroom-house for two or three weeks. This shed is open to the west, and shaded by some Chestnut trees. Could we manage it, we would place a line of hurdles along the open side, and draw green laurel boughs through them, so that the wind might pass between these before sweeping over the beds. A closer covering would do as well, but we found that hurdles so wattled

answered in winter, so long as we kept the beds on, and they were also useful in hot weather in July, for the shed is chiefly used for summer Mushrooms, though they often continue to produce all the winter. It is a low structure against a dwarf wall, and shaded by trees on the open side. We have twice had it rough-thatched with straw, using old bundles for the roof below the straw, and something must be done to renew it before long, but though we have once or twice been offered a tiled or a slated roof, we prefer the straw as a non-conductor of heat, and because coolness is the chief essential for Mushroom culture in summer. From this rough-thatched place we have had most of the advantages of a cool cellar in summer. We have tried a similar shed roofed with feather-edged boarding, and with tiles and slates well smeared with lime, to prevent the absorption of heat, but in neither case in hot summers did they act so well as the rough-thatched roof. Were it not for the harbour given to vermin, there is something more than the picturesque in thatched roofs for dwelling-houses for man, they are so cool in summer, and so warm in winter. As a mark of progress, it is pleasing to notice all through the country sheds and workshops close to the slates, having the slates outside well whitened, so that the people below should not be half roasted in summer, and frozen in winter. A friend had a small shed for summer Mushrooms erected against a wall, but he was too neat in his tastes to think of thatch, and too averse to the glaring in colour to think of a staring white roof, and to compromise the matter had the roof covered with brownish tiles. Even they proved too hot in July and August. After a little mutual thinking over of the matter, a pretty picturesque roof is now formed. A little earth was strewn over the tiles, and that was planted all over with the little green yellow-flowering Sedum acre, and it is now a dense mass, and in the hottest days of the last summer the lower side of the tiles felt quite cool to the hand.

Our chief difficulty with the shed beds for two seasons has been owing to the inroads of numerous moles. Tarring their runs has set them to make fresh ones, and some beds have looked in the morning as if a miniature plough had been at work all over the bed. In the garden and pleasure grounds nearly a hundred moles have been caught. They were not satisfied with Mushroom beds, but worked into Cucumber and Melon beds, everywhere in fact where the soil was at all soft, and though we find no great fault with their heaps in a meadow, as these make an excellent top-dressing, they do not look attractive on a lawn close to the principal windows. One of the best modes of trapping moles is for the trapper to carry a dead mole, or the skin of one, with him, and to draw that over the traps and the neighbouring soil, so as to take away all scent of his own hand. Looking on the mole as in many respects one of our co-operators, and admiring its indomitable energy and perseverance, we should be glad if some better means than have been noticed in these pages could be mentioned, to drive moles away from particular places, instead of trapping and thus killing so many of them. Our better feelings are apt to give way when we find a good Mushroom bed made for a time next to useless, and more especially when we know that the bed contained little that would suit the mole in the way of food, as, if the bulk of such beds were dry rather than wet, there would scarcely be a worm or other little animal for the mole.

We threw some droppings and litter into a heap to dry by fermentation in order to make another piece in the Mushroom house. Finished earthing a second piece and spawned a third, and will watch the latter for a few days. It is generally best in a shelved house to fill the upper shelves first, as these will then be assisted by the heat in the beds beneath them when getting ready.

FRUIT GARDEN.

We have housed all the hardy fruit at last. Apples seem to keep better than Pears. We have lost of the latter some splendid Marie Louise, Beurré Bosc, and Napoléon, and all required to be looked to often, as when they began to decay they soon became little better than a skiff of juice. With these exceptions the fruit has been good and of excellent flavour. That some should thus be excessively stored with juice might be owing to the wonderfully rapid swelling that took place after the first rains, and the more humid atmosphere which then prevailed. Before the rains came there was every appearance that the fruit would be small and deficient in moisture, but, on the whole, all Apples, Pears, and other fruit have turned out of fully their usual size.

From the orchard house we are still gathering every day Reine Claude de Bavay, a few Jefferson, and a good supply of Coe's Golden Drop Plums from pots, and with due preparation,

as previously instanced, we see no reason why the latter Plum should not keep well through November and part of December at least, and it would be difficult to find any other fruit at this season to beat it in quality. In the first house Figs and Grapes are ripening well.

ORNAMENTAL DEPARTMENT.

Much the same as in previous weeks; the falling leaves prevent the grounds being so clean as we would wish.—R. F.

COVENT GARDEN MARKET.—NOVEMBER 4.

OUR market remains so stationary, both as to supply and demand, at present, that we have little worth reporting. Broccoli of the different varieties have remarkably improved during the past fortnight, and Winter Greens are abundant. Pears now consist of Chamois, Glou Morceau, Winter Nelis, and Houtte Die; Apples of Ribston Pippin, King of the Pippins, Nonpareil, and Fearn's Pippin.

TRADE CATALOGUES RECEIVED.

F. and A. Dickson & Sons, 106, Eastgate Street, and Upton Nurseries, Chester.—*Catalogue of Roses.*

André Leroy, Angers, France.—*Descriptive Catalogue of Fruit and Ornamental Trees, Shrubs, &c.*

TO CORRESPONDENTS.

*. We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c.*, 171, Fleet Street, London, E.C.

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

BOOKS (T. M.).—"The Gardener's Assistant" is published by Blackie and Son, London. The "Cottage Gardeners' Dictionary Supplement" can be had free by post from our office for twenty postage stamps.

CHERRY PLUM (Miss King).—Any of the principal nurserymen who advertise in our Journal could supply it.

APPLE TREES (Medicus).—The six kitchen Apples that would suit your purpose are Bedfordshire Foundling, Alfriston, Dumelow's Seedling, York-hire Greening, Norfolk Beefing, and Tymer. The Prune Damson is the finest. For cider you had better consult some orchardist in your county—Hereford, for soil and climate have an all-controlling influence over the flavour of the cider, and the variety which produces an excellent liquor in one locality often produces an inferior liquor in another district.

LARGE PEAR (R. H. F.).—Your Pear is Haeon's Incomparable. The specimen sent was fine and high-flavoured, but deficient in sweetness and juiciness. This may be occasioned by its being grown against a south

wall, which it does not require, being very bardy. The fruit may be improved by mulching, in summer, the surface over the roots, and watering freely in dry weather.

FOREIGN EXPORTERS OF ORCHIDS (E. M. L.).—Our correspondent wishes to know the names of Orchid shippers at various places in the East and West Indies.

APPLYING SULPHUR TO VINES (H. C.).—There is a sulphurator which, by turning the handle, disperses the flowers of sulphur, much after the manner of a winnowing machine; but we find that the sulphur may be applied very effectively to the Vine leaves by the aid of a common flour-dredger. We have heard nothing more about "Sigma's" circular vineries. If we receive any information we will publish it.

ARIES NOBILIS SEED (F. P.).—That which you enclosed is not fertile; but we think that we have heard of its ripening seeds in England.

ROSES FOR EXHIBITION (T. W. Johnson).—"You wish for the names of Roses for exhibition, and for a suggestion of others. Of those you have named the following are very excellent:—Alfred Colomb, Madame Victor Verdier, Jules Margottin, Gloire de Dijon, Maréchal Niel, Charles Lefebvre, Pierre Notting, Prince Camille de Rohan, Comtesse de Chabrillant, Sénateur Vaisse, John Hopper, Souvenir de Dr. Jamain, Exposition de Brie, Marguerite de St. Amund, Marie Baumann, Dr. Andry, Abel Grand, Antoine Ducher, Madame Margottin, Lady Suffield, Baronne Adolphe de Rothschild, Triomphe de Rennes, Madame Alice Bureau, Acélide, Baronne Prevost, Charles Verdier, William Griffiths, Prince de Portia, Madame Charles Wood, Gloire de Vitry, which is splendid on its own roots; Princess Mary of Cambridge, not here, but known to me; and Baronne de Maynard, not exactly a show Rose, but lovely; a continuous and most abundant bloomer—a splendid white hedger. I advise you not to buy the new Roses named till I have proved them. If you will have novelties buy Marie Clodde, Madame Rolland (not Madame Roland), Vicomtesse de Vézins, Monsieur Noman, Duchesse d'Aoste, and Comtesse de Jaucourt. I suggest these:—Monsieur de Montigny, a splendid Rose, given up; Maréchal Vaillant; Madame Julie Paron, Leopold Premier;—put the last two in a shady place, they will then bloom freely;—Sombreuil (Tea), Souvenir d'Elise (Tea), Madame Willermoz (Tea), Souvenir d'un Ami (Tea), Adam (Tea), and Devonensis (Tea). These five, with Madame Margottin, are the cream of the Tea-scented Roses, and first-rate. Sombreuil is the hardiest of all. Mr. Taylor says Vicomtesse de Vézins will be first-rate for ten years, and Pitord (or Pitford) is superb.—W. F. RAEFLYCE."

PELARGONIUM, FUCHSIA, AND CALCEOLARIA CUTTINGS (Ignorance).—The Pelargonium and Fuchsia cuttings we would put in pots, drained with one-third their depth of broken pot; then nearly fill them with open sandy soil, and surface with sharp sand. Insert the cuttings about an inch apart round the sides of the pots, give a gentle watering, and, as you have only a dwelling-house to strike them in, place them in the most sunny window you have, being careful not to water as long as the foliage keeps from flagging. They ought to be kept from frost. The Calceolaria cuttings may be put in the shallow wood boxes, and in good loamy soil, but avoid the manure you have by the wagonload. Place a layer of sand an inch apart, giving a gentle watering, and placing them near some window. The soil should be kept moist, but avoid making it very wet. The pronunciation of Calceolaria is Calceolaria; Anemone, Anemone; and Ranunculus, Ranunculus.

TOP DRESSING POT VINES (T. I. M.).—Your Vine being in its fruiting pot and intended for bearing next year, it ought not to be repotted, but should have the drainage put in order, and as much loose soil from the surface removed as it is possible to do without injury to the roots. Then top-dress with loam from turf, adding one-fourth of old manure and one-sixth of half-inch bones, or a couple of good handfuls of bonedust.

POTTING FIG TREES (Idem).—The best soil for the Fig tree is loam neither heavy nor light, and if from the top 2 inches of a pasture it could not be better. It should be chopped or torn in pieces and made firm. The present is a good time to pot the tree.

COLEUS WINTERING (J. M.).—To winter this safely it should have no more water than enough to keep it from flagging, and the temperature should seldom be lower than 45° at night, though it may in severe periods fall to 40°. If, as you say, you want the plants to grow, the temperature should be from 55° to 60° at night, and from 60° to 65° by day. The best way to keep the Coleus is to have good little well-rooted plants by the end of summer, and to keep them gently growing during the winter in a stove or warm greenhouse, watering carefully, and affording them a light and rather airy situation. The temperatures named will be destructive to the greenhouse bedding plants.

GROWING MUSHROOMS UNDER A SUMMER HOUSE (T. M.).—We suppose that beneath your summer house is a sort of cellar. If so, it will answer admirably for growing Mushrooms; and being underground it will be secure from frost, except in very severe periods, and then you may cover the bed with dry short straw or hay.

VEGETABLE MARROWS AND CUCUMBERS AFTER POTATOES (Idem).—The Potatoes being off by the beginning of June, you may follow with Vegetable Marrows and ridge Cucumbers; but we should prefer planting the Potatoes in rows 3 feet apart, and having a row of Cucumbers between. Between the Potato rows a trench may be formed, which may be filled with hot dung, and covered with soil for the Cucumbers. Plant them out early in June, unless you can cover them with hand-glasses, then plant in the middle or third week in May. The Vegetable Marrows will do in rows 6 feet apart, so that you may have two rows Potatoes between the Marrows, which should be planted by the third week in May, and a flower pot inverted over them in frosty nights for a short time.

CUTTING BACK FUCHSIA (Idem).—The Fuchsia which is very straggling should be cut down, but not until spring when it begins to grow.

BEDDING PELARGONIUMS AND FROST (Idem).—Our experience is that they will not endure more than a slight frost, or one of a few hours' continuance; for no matter how dry the soil, their stems, being still succulent, will decay on becoming frozen.

PRUNING BLACK CURRANTS (Idem).—You are right as regards pruning Black Currants. Their shoots should be thinned out when they are too thick, and without shortening those left; but when they are not too numerous but very long, to encourage the production of young wood, they should be cut well back; and in order to keep the young trees low and well furnished with bearing shoots, the young shoots should be shortened

one-third or one-half their length. It is easy to thin them out, but not so easy to obtain young shoots from the bottom without losing a year's crop. The straggling bushes of former days are no longer imitated, the present mode being to shorten the young shoots, to keep the bushes dwarf and symmetrical, and by it even finer fruit is produced, as it is borne on young wood. Cut out the old wood, encourage young shoots, shorten them, and, if they become too numerous, thin out.

HEATING A FERNERY (A Grateful One).—As you cannot have either a flue or hot-water pipes, you may have a stove, with a chimney or pipe to take off the smoke, &c., which in most stoves is necessary; but there are some without flues or pipes. Write to the makers of stoves who advertise in our columns, stating the size of your house, and asking for prices, &c. We cannot recommend dealers.

SAPONARIA CALABRICA AND SILENE PENDULA FOR CARPETING TO HYACINTHS (Notice).—We fear neither would flower early enough for the Hyacinths, otherwise they would answer very well as to height. We do not know the bulbs you mention.

PARAFFIN OIL FOR DESTROYING MEALY BUG (York).—We can verify all you say as to this destroying every insect it touches. It is the best remedy for the American blight or bug, and for the scale on Pear and other trees in the open air. It should be applied with a brush, now being the best time to apply it—that is, after the leaves have fallen. We do not know what effect the vapour would have on plants in leaf, but as a destroyer of bug and scale on trees in active growth, and where there are no plants, we find it safe and effectual. You may employ it for destroying mealy bug on Peach trees, but we should for the present advise its being kept from the buds. If you were to syringe your tree when there was a likelihood of frost, and the water became frozen, that would destroy the bug and not injure the tree. We cannot name plants from leaves; flowers are necessary as well.

ALTERNANTHERA AMENA FOR BEDDING (A Constant Subscriber).—It would succeed in your locality and soil if good plants were turned out. It is easily propagated by cuttings. A few store plants kept through the winter in a temperature of from 40° to 45°, and placed in gentle heat in February, will afford an abundant supply of cuttings by the beginning of March. They should be inserted in a mild hotbed, when they will soon take root, and if kept growing will make good plants by bedding-out time. Being of very dwarf and compact habit, it is only suitable for edgings and carpeting, and not for centres. You will see, when you have the plant, what its foliage will best contrast with.

YUCCA FLOWERING (Francis Scott).—We should not cut off the flower stem, but allow it to flower, which will not, we think, destroy the plant.

CALCEOLARIAS FAILING (Subscriber).—They succeed well in a compost of two parts loam from turf taken from a rather strong but not very heavy loam, one part old cow dung, and one part leaf mould, with a free admixture of sand. You may take up any of the old plants that are dwarf and compact, preserving a ball of soil to each, and place them in pots that will hold the ball comfortably. They should not be cut-in, though any straggling shoots may be removed; and kept in a cool, light, and airy situation in a greenhouse they will flower well in spring. Your plants this year seem not to have had enough of moisture. For bedding purposes they are best propagated by cuttings put in before frost in a cold frame, kept there during the winter, and planted out in good rich soil early in April, moving them to their final quarters in May with a good ball of soil to each. The beds should be prepared with a good dressing of rotten manure or leaf mould. To keep down green aphids the plants should have a cool temperature, abundance of air, and be fumigated with tobacco before they are much attacked by the insects.

RANUNCULUS NOT SUCCEEDING (Idem).—The Ranunculus succeeds best in a rich, deep, heavy loam, damp, but well drained. You do not say what your soil is, but from the foliage mildew we presume that it is light, and in that case we would plant in November or early in December. In preparing the bed, trench it 2 feet deep or remove the soil to that depth, and replace it with fresh. A good barrowful of cow dung rather old, as much as a man can wheel, should be worked in to every three square yards. The top 4 inches of the bed must not have any manure. The best soil for the top is that from reduced turf, but a thin paring from immediately under the turf of an old pasture will answer well. The bed should be formed 3 or 4 inches above the surrounding level, for from the deep stirring it will sink, and on that account it should be made, if possible, in September, or planting early in November, which we would advise you to try, making the bed now and planting forthwith. If, however, your situation is cold and wet, it would be better to plant as early in February as the weather permits. In planting draw off the soil to the depth of 2 inches, place the roots on the surface, gently pressing the very large roots in, and raising small ones by putting a little soil under, so that the crowns may all be on the same level; cover with soil to a depth of 1½ inch above the crowns, taking care not to displace the roots in covering. No further trouble will be needed until the plants come up, when the opening around each plant caused by the forcing-up of the leaves should be carefully closed; this is best done by the hand, pressing the soil firmly all round. In very dry weather copious watering will be required, especially when the flower buds are forming, should the weather be dry at the time, but surface waterings are of no use, on the contrary they are injurious; by keeping the soil constantly moist under a hot sun the temperature is considerably reduced by the excessive evaporation, and the plants become "blind." When water is given it should be in sufficient quantity to reach the lowest fibres. The flowers should be shaded to prolong their freshness, and when over remove the shade, take up the roots when the foliage decays, and thoroughly dry them.

PRUNING HARDY FRUIT TREES (A. A. C. H.).—The best time to prune all the fruit trees and bushes you name is in November, after the leaves have fallen. It is much better done then than in spring, though in places where birds are troublesome in pecking the buds, the spring-pruning of some trees is desirable on that account, but we strongly advise pruning all trees in autumn, taking other means of making the buds distasteful to birds, or of scaring these. The trees in addition to the winter pruning, or when leafless, require summer pruning or stopping, which are distinct operations.

CLEANING ZINC LABELS (Idem).—The ink and corrosion on zinc labels may be entirely removed by rubbing them with sand paper, and they are then eligible for writing upon again.

COMPOST FOR CYMBELIAS (J. M.).—Old turf, rotten cow dung, cocoa-

nut fibre dust, and sand will grow nine-tenths if not all the plants at present in cultivation. For Camellias use two parts old turf, one part each of cow dung and cocoa-nut fibre refuse (best old), and one-sixth of sand, good drainage being necessary. We would, however, recommend in place of the above compost, that brought into notice in our Journal some time ago by Mr. Pearson, of Chilwell—viz., the fresh turf of an old pasture where the soil is a good sandy loam, cut from 1 to 1½ inch thick, tearing it in pieces with the hand, and using it in its fresh state. Put firmly, and for the surface use the finer parts of the compost after pulling it into pieces. This compost answers admirably.

SOIL FOR CYCLAMENS (*Idem*).—The old turf, cow dung, cocoa-nut fibre refuse, and sand above named, and in the same proportions, are an excellent compost, adding one-sixth of grit in pieces from the size of a pea up to that of a hazel nut, and mixing the whole well together. The best time to pot is when they are beginning to grow, which will vary with the species. *C. persicum*, for instance, should be potted in September, and if it grow well and fill the pot with roots it must be shifted into one of larger size, and in this way large plants with beautiful foliage may be had for blooming in spring.

TYDÆAS (*J. Bayly*).—If you consult a catalogue you will notice the Tydæas are distinguished from the Achimenes. None of them should be dried off like Achimenes, but be kept so moist at the roots as to prevent their foliage from flagging, though after flowering it is desirable they should have full exposure to light, and be kept rather drier. As the old stems go off cut them out, but not until the young shoots have made some progress. If the soil were kept so dry as for Achimenes whilst at rest, it is very likely the young shoots would not appear, and upon these depends the perpetuation of the plant.

INARCHING VINES (*Inquirer*).—We would prefer the Bowood Muscat to be inarched on the White Nice, but any Muscat that is preferred will do. If we had any preference at all, we would place Mrs. Pince on the Lombardy, but the influences of stock and scion are sometimes singular in Grapes.

BOTTOM HEAT IN A CUCUMBER HOUSE (*Jersey Subscriber*).—Were we in your position we would make a concave bottom of concrete below the pipes, within half an inch of the bottom of pipes, and round and above the pipes place clinkers, &c., as loosely as possible, terminating with a layer of clean-washed gravel below the soil; but provided this is done, have the pipes as near the soil as possible. See page 283, on bottom heating, and were we to write a number we could not better summarise the matter.

FRUIT-TREE CULTURE (*Cornubia*).—You will see a communication from "C. C. E." before many days have passed.

KEEPING WALNUTS (*A. B.*).—See what is said in "Work for the Week."

SEEDLING PELARGONIUM (*John Hodgson*).—The truss is large and each pip fine; but it is impossible to judge of the merits unless an entire plant is seen. Send one to the Floral Committee of the Royal Horticultural Society.

RASPBERRIES (*G. J. Butterfield*).—We recommend you to plant the Fast-tall and Yellow Antwerp. Have a space of 4 feet between the plants, and insert them now.

TRICOLOR PELARGONIUM REPRODUCING ITSELF (*Persist*).—All will very frequently be reproduced if fertilised with their own pollen; they will also very frequently reproduce the original parent varieties, as far back as the third or fourth generation.

SOIL FOR AZALEAS—CARBOLIC ACID AMONG PLANTS (*S. S.*).—Nothing suits Azaleas so well as sandy heath soil with a little very old sweet cow dung. The stronger sorts may have a little fibrous loam. We would not use carbolic acid on the floor of a greenhouse. What say others more experienced?

ORCHID BASKETS (*F. Briggs*).—We have no recollection of them. They may be excellent, yet not remembered among the contrivances sent to us six years ago.

EXHIBITING CHRYSANTHEMUM BLOOMS (*D. L.*).—Stands and wooden tubs similar to those employed for Dahlias are used. We do not know where they are to be had. Your best plan would be to apply to some of the leading Chrysanthemum nurserymen.

CLUB ROOT IN CARBAGES (*Inquirer*).—We see in an American paper that bonedust applied at the rate of 2000 lbs. to the acre has been found a complete preventive of this disease. The bonedust must be offensive to the insect, the grubs from whose eggs cause the swelling and decay.

ROSES—ERRATUM.—Page 326, 2nd column, line 4. I intended to say:

"Of the thirteen Roses named, I should not think highly of *La Reine* François Lacharme (which requires high cultivation), *Duchesse de Cambrésis*, *Duchesse de Caylus*, *Madame Julie Daran*, two first-class roses; *Michel Bonnet*, *Madame Charles Wood*, and *Madame Gustave Bonnet* may be retained."—W. F. RADCLIFFE.

TAR WATERPROOFING (*Litharge*).—This is altogether a bad time to make waterproofed cloth with tar, &c. We have used a pint of linseed oil to two quarts of coal tar, brushing it on when warm—say about 170°, and it answered the purpose, but having done these things on a small scale, and to suit particular purposes, we do not feel it would be safe for us to enter into the specific inquiries you make on the subject.

VINES UNFERTILE (*G. P. Ireland*).—You do not tell us sufficiently the state of the Vines. Is the drainage all right? Are the Vines very strong, with large foliage? Then well draining and extra firing to ripen the wood will make them fruitful, in addition to what you have done for them. If they are tolerably strong, retain their leaves long, and cut a little pithy, then the roots are too deep, and had better be lifted and replanted a foot from the surface in fresh fibrous loam. Most likely the drainage and a little more heat will do all that is wanted. If the roots are deep the Vines will succeed best on the rod-pruning system, instead of cutting-in to a bud or two. Send fruit in a box, each wrapped in paper and carriage paid throughout. Each specimen to be numbered.

LIME AND LEAVES (*A Subscriber*).—Put a thin layer of leaves, sprinkle slaked lime over them, and a little salt too, and proceed thus with the whole. The object is to reduce the whole to a mass capable of being dug into the soil; and at the same time to kill insects and fungi. Gas lime would not be so beneficial.

APPLES AND PEARS (*Centurion*).—The Yellow Bellefleur is an American Apple, it is not the same as the Brabant Bellefleur. Neither it nor any of the other Apples you name merit a south wall. Lime spread thickly over the surface round your Pear trees might destroy some of the grubs in the soil before they emerge in their insect state to deposit eggs on the leaves. The White Doyenne does not require a wall. *Glou Morcean*, *Winter Nelis*, and *No Plus Mouris* deserve a south aspect.

HEATING BY HOT WATER IN TROUGHS (*A Tyro*).—See page 283 as to failures in bottom-heating. Your troughs will give plenty of heat if the water is 3 or 4 inches deep, instead of 6 inches—that is to say, if the boiler will not easily make the 6 inches warm from top to bottom. Then your proposed plan of covering the pipes with slate will do; in such a place the chamber will be an advantage. You had better make the slate covering close over the tank, and then the upright pipes from the chamber can admit either dry air or moist air at pleasure. Such a pit will do admirably for Beans, Cucumbers, &c. On reading page 293, you will see what is necessary for continuous bottom heat. So far as we understand it, we have no faith in your second plan. Why do away with the boiler when you have it? The third plan is also very inferior to the first plan. Never lose dry heat from fire in any shape, to be replaced with dung heat alone. When you cannot help yourself, it is a different affair. You cannot grow Cucumbers and Potatoes in the same pit unless you have a division, and keep the Potato end from 15° to 20° cooler than the Cucumber end.

NAMES OF FRUITS (*John Shepherd*).—Your Pear is Vicar of Winkfield. (*W. G. Newcastle*).—Ravelston Pippin. (*Morston*).—The long Pear is Vicar of Winkfield, and the other Arlequin Musque. (*T. H. R.*)—All that we can identify are—1, Doyenné Boussoch; 2, Adèle de St. Denis; 13, Broompark; 15, Tardif de Mons; 16, Deux Sœurs. Some are very fine specimens. (*D. R. Wrexham*).—Dutch Miguonne; 3, Franklin's Golden Pippin; 4, Ord's; 5, Beauty of Kent; 6, Hollandbury; 8, Marnslade Pippin. (*A. M.*)—1, Beurre d'Esp; 2, Verulam; 3, Beurre d'Esp; 4, Beurre d'Aremberg; 7, Princesse Charlotte; 9, Jean de Witte; 10, Fondante d'Automne; 11, Nouveau Poiteau; 12, Passe Colmar. (*T. E.*)—1, Grosse Calebasse; 2, Monarch; 3, Fondante de Malines; 4, Broompark; 5, Colham; 6, Cornish Aromatic; 8, Franklin's Golden Pippin; 10, Dumelow's Seedling; 12, Golden Pearmain; 15, Kentish Filbasket; 16, Dumelow's Seedling, Norfolk Colman; 18, Barcelona Pearmain; 19, Christie's Pippin.

NAMES OF PLANTS (*J. R. Pocock*).—*Salisburia adiantifolia*, or Maiden-hair Tree. (*R. F. S.*)—We cannot name plants from leaves only. (*M. Coleridge*).—*Salvia Grahami*. (*W. M. Leves*).—*Athyrium Filix-femina* *Erigeron*; 2, *Lomaria discolor*. (*C. M. Major*).—*Pteris arguta*. (*J. Bryan*).—1, *Adiantum hispidulum*; 2, *A. formosum*; 3, *Coniogramma javanicum*; 4, *Cypripedium elegans*. (*J. H. V. Leyland*).—Too much crushed to be recognised.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the week ending November 3rd.

DATE.	BAROMETER.		THERMOMETER.				Wind.	Rain in inches.	GENERAL REMARKS.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

THE NIGHT SIDE OF FOWL-FANCYING.

I READ the account of "E. M. B. A.'s" troubles, in page 308, with keen interest and genuine sympathy, but I cannot think

that the much-prized pullet died, as its owner seems to suppose, of roup or roup's remedy. The death, far more probably, has been caused by overfeeding or poison. I am surprised that "E. M. B. A." neglected to submit his favourite fowl to a *post mortem* examination. Traces of poison could easily have been detected by an expert practitioner, should poison have been administered; if, on the other hand, death had been occasioned

by excess of food, the proofs would have been plainer still—"E. M. B. A." concludes the narrative of his woes with a statement that for the future he means to invest in nothing but Bailey's Roup and Condition pills, which, as far as my experience extends, are a most valuable and efficacious medicine; should they, however, fail to cure a case similar to the one above-mentioned, I hope that "E. M. B. A." will refrain from "hurling them into the fire" until he has satisfied himself thoroughly as to the nature of the disease that the pills were expected to cure. It would be hard indeed to expect roup and condition pills, however good, to serve as an antidote to poison, or a cure for paralysis, inflammation of the stomach, and a variety of other ills by which our feathered friends are liable to be attacked.—H. S. FRASER, *Headley, Hants.*

LIGHT-COLOURED BRAHMA POOTRAS.

In your last number you notice the forthcoming Southampton Show, and mention the cup contributed by Light Brahma breeders, the most valuable prize given in the Show, for the best pen of Light Brahma chickens. Allow me, as one who exhibited Light Brahmas when they had but few friends, and no prizes offered them, and who has seen them grow with but little help from shows, into one of the largest, in some cases the very largest class, at our exhibitions, to thank you cordially for giving expression, as you did last spring, to the feelings of so many friends of the Light Brahmas, and to assure you that those utterances have borne fruit in an increased number of Light Brahma classes. And now Southampton, which through its excellent Secretary has liberally recognised the claims of the "Lights," is at hand, and the largest classes there will be those for Light Brahmas, so that these birds may fairly hope to compete for the cup for the best pen in the show.

All that we exhibitors want now, is good and careful judging, and that we shall have, if our leading judges officiate, with one proviso—namely, time enough allowed them, which is not the case everywhere, so that they may have the opportunity for careful examination, and not merely look at size, or symmetry, or colour, but notice and compare the special points—for example, the comb, which in Brahmas, both Light and Dark, is not always so good as it should be even in prize-winners.—JOHN PARES.

BRISTOL AND CLIFTON POULTRY SHOW.

In the early part of this year, had I been asked when there would be another show at Clifton, in somewhat doleful mood I should have replied, Never! Twice bitten is once too often; but whatever may be the fortunes of our Bristolian friends, there is one quality that cannot be denied to them—that is, pluck. They have held two decidedly unfortunate shows as regards the poultry exchequer, though graced in every other way; yet, nothing daunted, here they are again, with a schedule more inviting than ever, and an array of silver cups, twenty-two in number, varying in value from £3 3s. to £10 10s.

Dorkings have eight classes, and two silver cups; Cocks twelve (!) classes, and two cups; Brahmas eight classes, and two cups; Spanish four classes, and two cups; French fowls two classes, and two chances of cups; Hamburgs eight classes, and two cups; Game six classes, and two cups; Bantams eight classes, and four cups; Any other distinct variety, two classes. Polish, I regret to say, have only two classes. No division into classes of these truly ornamental fowls, even to our friend "NEWMARKET'S" idea, in spite of the splendid array in the Show held two years ago, when it may be justly said this class was the gem of the collection! Malays, too, that made a fair muster two years ago, certainly larger than some of the retained classes, are unceremoniously cut out altogether. Ducks have four classes; Geese and Turkeys one each.

The Dorking, Cochin, Brahmas, Spanish, French, Hamburg, Polish, and Any other variety, have classes of single cocks and pairs of hens. This is a very good change. In the Game, the classes are single cocks and single hens; the latter might have been advantageously extended to the Game Bantams, but these classes consist of a cock and two hens, with the addition of two classes for single cocks. After the Bantam classes, the remaining classes are composed of one male and one female. These, the Duck, and the Geese classes, are not fairly dealt with. The entry-fee being the same for each class, it is not, to my thinking, just to give prizes so disproportionate in value. For instance, the same entry has in many classes prizes to the value

of £5, but in Geese and Ducks only £3. The entry is 7s. 6d. per pen. This is full high. I should have thought 6s. ample; the present, however, is a far better arrangement than making it necessary to subscribe 5s. first before entering, or that of making the first entry 15s., two for 20s., and so on.

Each exhibitor will have one not-transferable ticket of admission. Personally I object, for the sake of the birds, to exhibitions being open till 10 p.m. Still, with what little blots there may be on the escutcheon, Bristol pluck deserves success. I hope they will get it. As it is "the third time of asking," may there be nothing either in weather or any other drawback to forbid the banners between the Bristol and Clifton Poultry Show, and a paying crowd of visitors.

I forgot to mention that there are fifteen classes for Pigeons, with two prizes in each, and three silver cups also devoted to Pigeons.—Y. E. A. Z.

THE LONDON POULTRY MARKET IN EDWARD 1ST'S REIGN.

In 1274, Henry le Waleys being at the time Mayor of London, a civic ordinance was issued, that no *Poletria*—that is, no dealer in poultry, should fore-stall the market by going out of the city to buy, nor buy even within the city, until the purchasers for the King, lords, and citizens had completed their bargains—namely, until after three o'clock. The prices were also fixed—a good fowl, 1*d.*; a good Capon, 2*d.*; a fed Goose, between Easter and Whitsuntide, 5*d.*, and from Whitsuntide until the festival of St. Peter ad vinculas, 4*d.*; and for the remainder of the year, 3*d.*; an "Ancam roseram," 4*d.*; three young Pigeons, 1*d.*; a Pheasant, 4*d.*; a Swan, 4*s.*; a good Peacock, 1*s.*—(*Liber Custumarum.*)

BLACK-LEGGED FOWLS.

In your number for October 22nd was a very sensible letter on the folly of the objection to dark-legged poultry for table. I can fully corroborate that. I have for many years kept Polish fowls, which have blue legs, and I generally have to kill some which are imperfect in feather, or otherwise not up to the mark. They are most excellent in flavour; in fact, I do not know a fowl, which for its size, is so good as the Polish. Not being large, it is, perhaps, not so much esteemed as some, but for plumpness and general excellence, I quite believe that there is not a better fowl than the Polish.—G. W. BOOTHBY.

PIGEON PRIZES.

WE are authorised to state that Messrs. John Bailey & Son offer for the Birmingham and Manchester Shows of 1869, at each place, a silver cup or other piece of plate, value five guineas, for the best pair of Rants exhibited.

EXHIBITORS AND JUDGES OF PIGEONS.

My last letter on the subject of dealers being allowed to exhibit in competition with fanciers, and on the custom of showing birds that are not pairs, having met with general approval in the fancy, I venture to address a few words to you on another subject—namely, the objectionable practice of exhibiting borrowed birds.

There was a time when the most conscientious exhibitors would borrow or lend a bird or two, and look upon the act only as a proof of kindly feeling, but since Committees of so many of the principal shows have begun giving cups to the most successful exhibitors, the custom of borrowing and lending birds for showing has become so general and so extensive that it is likely to be a means of bringing the fancy into disrepute.

Fanciers ought to consider that they do a great injustice to the man who only exhibits about a dozen pens or so, as it is an absolute impossibility for such a man to win a cup for the most points. I cannot be charged with selfish motives in writing this, as I never show more than half a dozen pens at once. I take the practice on the broad basis of right and wrong.

In certain quarters, and from interested motives, one particular "firm," as the phrase goes, has been pretty roughly handled, but we should bear in mind that we ought not to make one offender the scapegoat for the rest. The offence was committed by more than one, both at Birmingham and

Glasgow, and at the last Halifax Show there were no less than four of these combinations, and by the most prominent exhibitors too. Now, I ask, if it is not time for this to be discontinued?

There is another matter which I wish to name, and that is the appointing of judges. The confidence of exhibitors has been very much shaken, and Committees ought to be careful to appoint judges of the highest ability and integrity. For my own part I consider Messrs. Corker, Cottle, Hedley, Weir, and Charlton to be all first-class Pigeon judges, and I think the Committees of large shows would do well to secure the services of some of the number.—J. FURTH, JUN., *Webster Hill, Dursbury.*

IPSWICH POULTRY SHOW.

THE third annual meeting of the Ipswich Poultry Association has just closed, and with an increase of upwards of one hundred entries over the shows preceding it. The quality of the birds shown has also improved quite as much as the number of competitors. This is, of course, most gratifying to all parties, and the Show, thus fairly established, promises to vie with the largest of our poultry exhibitions. Great praise is due to the indefatigable Honorary Secretary, Mr. W. B. Jeffries, a gentleman who is always at his post, and ever willing to do the utmost to oblige every one who has any interest in the exhibition.

As to the arrangements for the Show, they are somewhat hurried owing to the very short time available after the conclusion of the market in the Corn Exchange, for putting all the pens in readiness for the birds. If, also, those varieties whose excellence depends generally on ground colour and marking, could be placed in the upper tier of pens instead of the lower one, they would be far more readily judged, and more easily inspected by visitors. The care taken by the Committee of the birds consigned to their trust, merits our highest praise.

The *Game* classes were excellent, Messrs. Fletcher & Matthew being very desirous to secure the Society's silver cup. It was taken by the latter gentleman's Duckwings, the other *Game* prizes falling pretty equally to both of those well-known *Game* breeders. *Dorkings* were unusually good, but many pens had been overshadowed. *Cochins* were first-rate classes, especially the Buff hens, and pairs of the Partridge-coloured ones. In the class for pairs of *Cochin* hens, two pens of Buffs were shown that are only very rarely equalled. *Hamburghs* were exceedingly good, and decidedly beyond precedent at Ipswich. In *Polish* only three pens competed, one a very good pen, but the birds so much overshadowed as to be listless, the cock was almost thoroughly exhausted; the first prize, consequently, was withheld. The *Brahma* cockerels were decidedly good, but with the exception of a pen or two the pullets were just as indifferent in markings and colour. The class for *French Fowls* was one of the best in the Show. The Selling class was a great success, and the *Pigeons* comprised numbers of the very best pens in the fancy.

This Show, as too frequently the case of late at many others, had many empty pens, upwards of 50, the birds for most of which arrived "too late for competition." When we state that judging did not begin until long after mid-day, that the birds by the rules were to be in the night before, that pens were coming in at intervals all the afternoon, and some so late as 6.30 p.m., after all the decisions were finally given in, we cannot but express a hope that some fresh arrangement may be made, particularly as so late in the year forenoon judging is most to be depended upon, and the most beneficial also to the interests of exhibitors. Certainly the last consignment of pens would have obtained four first prizes had they been received in time for general competition. These mishaps are annoying to all parties concerned.

Before closing our remarks, we cannot but briefly allude to the serious state of ill health from decided roup, that not a few pens of Bantams manifested. It is serious in two ways, it entails almost certain death on the birds so suffering, and again brings about every probability of contagion to other birds placed near them.

A very extensive and pretty collection of *Pheasants* was shown, and the general collection of *Ducks*, *Geese*, and *Turkeys* was magnificent. There was also a good show of *Cannaries*, and other *Singing birds*. The weather was favourable.

GAME (Black-breasted and other Reds).—First and Third, J. Fletcher, Steneclough. Second, S. Matthew, Stowmarket. Commended, S. Matthew; R. Hall, Cambridge; C. F. Hore, Tunbridge; Rev. F. Watson, Kelvedon.

GAME (Any other variety).—First, Cup, and Highly Commended, S. Matthew (Duckwings). Second, W. Gray, Margarettin. Third, J. Fletcher *Hens or Pullets*.—First, Rev. F. Watson (Black Red). Second, S. Matthew, Highly Commended, G. M. Sexton (Black Red). Commended, S. Matthew; H. Lee, Appuldreham; R. Hall.

DORKINGS (Any variety).—First and Cup, F. Parlett, Great Baddow. Second, Viscount Turnour, Shillingee Park, Petworth. Third and Highly Commended, D. C. Campbell, M.D., Brentwood. Commended, J. Frost, Parham; H. Lingwood, Needham Market. *Hens or Pullets*.—First and Second, D. C. Campbell, M.D., Very Highly Commended, H. Lingwood, Highly Commended, Viscount Turnour; A. Beaumont, Ipswich; C. F. Hore, Commended, J. Frost; Hon. W. H. W. Fitzwilliam, Westwood House.

COCHIN-CHINA (Cinnamon or Buff).—First, Mrs. P. R. Burrell, Ipswich. Second and Third, H. Lingwood. Commended, C. Sidgwick; F. W. Rush, Hastings; H. Maplebeck, Moseley, Birmingham.

COCHIN-CHINA (Any other colour).—First and Cup, E. Tudman, Whitchurch. Second and Highly Commended, Horace Lingwood, Martlesham.

Third, J. R. Rodbard, Wrington. Commended, C. Sidgwick, Ryddlesden Hall, Kitchley; J. K. Fowler, Aylesbury. *Hens or Pullets*. First, H. Lingwood. Second, H. Maplebeck. Highly Commended, Rev. G. Gilbert, Claxton; Mrs. P. R. Burrell. Commended, Mrs. Pattison, Malden; Rev. C. Spencer, Attleborough; Horace Lingwood.

BRAMA POOTRA (Any variety).—First, Mrs. P. R. Burrell. Second, Hon. Mrs. A. B. Hamilton, Ridge mount Vicarage. Third, Major C. J. Ewen. *Hens or Pullets*.—First and Cup, Hon. Miss D. Pennant, Penrhyn Castle, Bangor. Second, J. K. Fowler. Highly Commended, H. P. Leach, Woolpit; S. Felgate, Ipswich; Mrs. Woodcock, Rearsley House; Mrs. Astley, Tring.

FRENCH FOWLS.—First and Third, Col. Stuart Wortley, London. Second and Highly Commended, J. K. Fowler (La Fleche and Crève-Cœur). Commended, O. E. Cresswell, Banworth (Bandon); W. Dring, Faversham (Crève-Cœur).

SPANISH.—First and Cup, H. Beldon, Goldstock. Second and Highly Commended, H. Browne, Putney Heath. Third, G. M. Sexton. *Hens or Pullets*.—First and Second, F. James, Peckham. Commended, H. Browne; M. Farrand, Duddersfield.

HAMBURGS (Golden-pencilled).—First, J. R. Jessop, Hull. Second, W. K. Tickner, Ipswich. Third, H. Beldon. Very Highly Commended, G. Clarke, Long Sutton; W. & T. Bairstow, Fearncliffe, Bingley. Commended, W. Turner, jun., Ipswich.

HAMBURGS (Silver-pencilled).—First, E. Pittis, jun., Newport, Isle of Wight. Second, G. Clarke. Third and Highly Commended, H. Beldon. Commended, J. R. Jessop; Viscountess Malden, Hartford.

HAMBURGS (Golden-spangled).—First, H. Beldon. Second, J. Laming, Cowhorn. Third, T. Walker, jun., Denton. Highly Commended, H. Beldon; S. & R. Ashton, Mottram. Commended, W. McMillan, Glossop.

HAMBURGS (Silver-spangled).—First and Cup, H. Lee. Second, H. Pickles, jun., Earby. Third and Highly Commended, H. Beldon. Commended, Wren & Ely, Lowestoft.

HAMBURGS (Any variety).—First, T. Fenn (Silver-spangled). Second, Mrs. P. R. Burrell. Highly Commended, H. Beldon; F. Pittis, jun.; J. Roe, Hadfield; W. Turner, jun., Ipswich (Gold-spangled); W. K. Tickner, Gold-pencilled.

POISH (Any variety).—Second, H. Beldon. Third, Mrs. P. R. Burrell. **ANY OTHER DISTINCT VARIETY**.—First, C. Sidgwick. Second, J. K. Fowler. Highly Commended, T. Walker, jun.; Mrs. P. R. Burrell.

GAME BANTAMS.—First and Cup, W. Adams, Ipswich. Second, G. M. Sexton. Third, Rev. C. H. Crosse, Cambridge. Very Highly Commended and Highly Commended, Miss Kate Croeland, Wakefield. Commended, J. J. Cousins.

BANTAMS (Any other variety).—First, Mrs. Woodcock (White Japanese). Second, E. Cambridge (Black). Third, H. Draycott, Humberstone. Highly Commended, J. R. Jessop; T. Walker, jun. (Black); Rev. F. Tearle. Commended, G. Manning (Golden Seabright); S. & R. Ashton (Black); H. Beldon.

BANTAMS (Any variety).—First, Miss E. Croeland. Second, E. Cambridge (Black). Highly Commended, J. J. Cousins (Gauc). Commended, Rev. E. S. Tiddeman, Brentwood (Black Red); E. Frentice, Stowmarket (Game).

SELLING CLASS (Any variety).—First, J. R. Rodbard (Partridge *Cochin*). Second, J. Frost (Coloured *Dorkings*). Third, Mrs. P. R. Burrell (Aylesbury Ducks). Very Highly Commended, W. Tippler (Hendon). Highly Commended, Mrs. W. Brackenbury, Downham (Spanish); G. Manning, Springfield (Golden Seabright). Commended, J. K. Fowler (Silkies); Mrs. P. R. Burrell (*Cochins*); G. M. Sexton (Buff *Cochins*); H. Beldon; D. C. Campbell, M.D. (Coloured and White *Dorkings*).

DUCKS (Duck).—First, S. H. Stott, Rochdale. Second, J. K. Fowler. Third, F. Parlett. Highly Commended, A. Robertson, Kilnamock. Commended, Hon. Mrs. A. B. Hamilton.

DUCKS (Aylesbury).—First, Mrs. P. R. Burrell. Second, Mrs. Seamons. Third, J. K. Fowler. Highly Commended, Mrs. Pattison; J. K. Fowler; Mrs. Seamons; Mrs. P. R. Burrell. Commended, E. Lawrence, South Wood.

DUCKS (Any other variety).—First and Second, T. C. Harrison, Hull. Highly Commended, F. Pittis, jun. (Black East Indian).

TURKEYS (Any colour).—First and Highly Commended, J. Berners. Second, G. M. Sexton. Commended, S. H. Stott; E. Packard, jun., Bramford.

GESE (Any variety).—First, J. K. Fowler. Second, Mrs. Seamons. Very Highly Commended, S. H. Stott. Highly Commended, J. Berners; Mrs. W. Brackenbury (White).

PHEASANTS (Any variety).—First, P. Podd, Ipswich (Giddy). Second, F. Waller, Ipswich (Gold). Very Highly Commended, Mrs. P. R. Burrell (Silver). Highly Commended, J. K. Fowler (Kalege); Mrs. P. R. Burrell (Gold).

SINGLE COCKS.

GAME (Any variety).—First, S. Matthew (Brown Red). Second, J. Fletcher. Highly Commended, S. Matthew; G. M. Sexton (Brown Red).

DORKINGS (Any variety).—First, Miss Hales, Canterbury. Second, W. King, Ipswich. Highly Commended, Viscount Turnour; D. C. Campbell, M.D.; Mrs. Seamons, Aylesbury. Commended, F. Parlett.

COCHIN-CHINA (Any variety).—First and Commended, Horace Lingwood (Partridge). Second, C. Sidgwick (Buff).

BRAMA POOTRA (Dark or Light).—First and Commended, Mrs. P. R. Burrell. Second, H. P. Leach.

SPANISH.—First, H. Beldon. Second, H. Browne. Commended, Hon. Miss D. Pennant.

HAMBURGS (Any variety).—First, Rev. F. Tearle, Newmarket. Second, H. Beldon. Highly Commended, W. K. Tickner.

BANTAMS (Any variety).—First, G. M. Sexton (Black Red). Second, R. R. Parker, Ipswich (Black Red). Highly Commended, E. Sheerman, Chelmsford (Pile Game); C. F. Hore (Black Red). Commended, J. J. Cousins (Black Red); Rev. F. Tearle.

ANY OTHER DISTINCT VARIETY.—First, Col. Stuart Wortley. Second, H. Beldon. Very Highly Commended, Mrs. P. R. Burrell (Hondans). Highly Commended, H. Pickles, jun. (Silver Poland). Commended, Miss Hales; J. K. Fowler (Silkies).

PIGEONS.

CARRIERS (Any colour).—First and Highly Commended, R. Fulton, Deptford. Second, P. H. Jones, Fulham.

POUTERS (Any colour).—First and Second, R. Fulton. Highly Commended, P. H. Jones.

TUMBLERS (Almond).—First and Second, R. Fulton. Highly Commended, P. H. Jones.

TUMBLERS (Any other variety).—First and Second, R. Falton (Agate, Mottled and Shortfaced). Highly Commended, P. H. Jones.

JACOBIANS (Any colour).—First, P. H. Jones. Second, R. Falton. Highly Commended, J. Percival.

FANTAILS (Any colour).—First, C. Baker, Atherstone. Second, H. Yardley, Birmingham. Highly Commended, P. H. Jones.

TRUMPETERS (Any colour).—First, P. H. Jones. Second, E. Sheerman.

TURBITS (Any colour).—First, P. H. Jones. Second, J. Percival.

BARBS (Any colour).—First and Highly Commended, P. H. Jones. Second, R. Fulton.

MAGPIES (Any colour).—First, J. Percival. Second, H. Yardley. Highly Commended, C. Baker.

ANY DISTINCT VARIETY.—First and Second, P. H. Jones (Blue Owls and Yellow Dragons). Highly Commended, Mrs. W. Woodhouse, Lynn (Blue Beards); P. H. Jones (White Owls). Extra Prize, Miss Hales (Bagadotte). Commended, Mrs. W. Woodhouse (Blue Baldheads); Rev. F. Watson (English Blue Owls); H. Yardley; P. H. Jones (Nuns).

SELLING CLASS (Any variety).—First and Second, P. H. Jones (Barbs and Dragons). Highly Commended, C. Baker (Blue Fantails); P. H. Jones (Fantails); J. Percival (Brunswicks). Commended, G. M. Sexton (Red Barbs); D. H. Feltham, Mildmay Park, London (Dun Carriers); Rev. F. Watson (English Blue Owls); H. Yardley.

CAGE BIRDS.

CANARY (Clear Yellow).—First, G. J. Barnesby. Second, Third, and Commended, R. Mackley, Norwich. Very Highly Commended, T. Fenn; G. J. Barnesby. Highly Commended, T. Fenn.

CANARY (Clear Mealy).—First and Second, R. Mackley. Third, G. J. Barnesby. Highly Commended, T. Fenn; G. J. Barnesby. Commended, T. Fenn.

CANARY (Mottled Yellow).—First and Highly Commended, R. Mackley. Second, Third, and Commended, T. Fenn. Very Highly Commended, R. Mackley; T. Fenn.

CANARY (Mottled Mealy).—First and Very Highly Commended, R. Mackley. Second, G. J. Barnesby. Third and Commended, T. Fenn.

CANARY (Mottled Crested Yellow).—First and Third, W. C. Williams, Ipswich. Second and Commended, T. Fenn. Very Highly Commended, W. C. Williams; R. Mackley. Highly Commended, R. Mackley.

CANARY (Mottled Crested Mealy).—First and Third, T. Fenn. Second and Highly Commended, R. Mackley. Very Highly Commended, G. J. Barnesby.

CANARY (Belgian).—First and Second, R. Mackley.

CANARY (Lizard).—First, Second, and Very Highly Commended, T. Fenn.

GOLDFINCH MULE (Yellow).—First and Second, G. J. Barnesby. Third, T. Fenn.

GOLDFINCH MULE (Mealy).—First, Second, and Third, G. J. Barnesby. Very Highly Commended, R. Mackley. Commended, T. Fenn.

ANY OTHER VARIETY OF MULE.—First, G. J. Barnesby (Linnets). Second, R. Mackley.

SELLING CLASS (Any variety).—First, Second, Third, and Very Highly Commended, T. Fenn. Highly Commended, R. Mackley; T. Fenn. Commended, R. Mackley.

LINNET, GOLDFINCH, OR OTHER ENGLISH FINCH.—First, Second, and Third, T. Fenn. Very Highly Commended, A. T. Cole. Highly Commended, J. Clover, Ipswich.

ANY OTHER CAGE BIRDS.—First, Second, and Third, T. Fenn.

EXTRA CLASS.—Extra Prize, Hon. Mrs. Paget, Seale.

The Judges were for *Poultry*, Mr. E. Hewitt, of Birmingham; for *Pigeons*, Mr. Tegetmeier, of London; and for *Canaries &c.*, Mr. Wilmore, London.

CHESTER POULTRY SHOW.

This was held on the 28th and 29th of October, and was very successful both as regards the number of entries and the attendance of visitors. Subjoined is a list of the awards.

GENERAL COMPETITION.

DORRINGS.—First, Arkwright. Second, A. Potts, Chester. Highly Commended, J. P. Campbell. Commended, Arkwright.

SPANISH (Black).—First, W. Woolley. Second, J. Walker. Highly Commended, W. R. Bull, Newport Pagnell; H. Wilkinson; J. Walker.

GAME—Cock.—First, J. Wood. Second, C. W. Brierley. *Hens or Pullets*—First, J. Wood. Second, W. Bourne. Highly Commended, Wilcox.

COCHIN-CHINA (Any variety).—First, T. Bott, Elton, Rury (Buff). Second, B. L. Lowndes (Partridge). Highly Commended, C. Sidgwick, Keighley (Buff).

BRAHMA POOTRA.—First, W. Hargreaves, Baemp. Second, Hon. Miss Douglas Pennant, Penrhyn Castle, Bangor. Highly Commended, E. Leech; Hon. Miss Douglas Pennant; J. K. Fowler, Aylesbury.

GAME BANTAMS.—First, J. Henshall. Second, R. Cooke. Highly Commended, R. Barton, Birkenhead; J. Holmes, H. Goulden.

ANY OTHER BREED.—First, J. Sichel, Timperley (Crève-Cœur). Second, P. Unsworth, Louton (Silver-spangled Poles). Highly Commended, P. Unsworth (Black Poles); J. K. Fowler (Fren. Lb); Hon. H. W. Fitzwilliam, Wentworth Woodhouse (Crève-Cœur).

DUCKINGS (Aylesbury).—First, F. Leech. Second, J. K. Fowler.

DUCKINGS (Rouen).—First, J. Wood. Second, C. W. Brierley, Heywood. Highly Commended, J. J. Stott, Rochdale.

LOCAL COMPETITION.

DORRINGS.—First, E. Roberts, jun. Second, T. Burgess. Highly Commended, Earl Grosvenor. *Chickens*.—First, Cup, and Second, Miss Davies. Highly Commended, A. Potts, Chester; Bury & Barlow; Earl Grosvenor.

SPANISH (Black).—First, R. Hulse. Second, S. & R. Ashton, Mottram. *Chickens*.—First, Cup, and Second, W. Woolley. Highly Commended, R. Davies; W. Woolley; J. Johnson.

GAME COCK (Any variety).—Cup, J. Platt, Swanlow. Highly Commended, Bury & Barlow (Black-breasted Red).

GAME (Black-breasted Red).—First, R. Ashley. Second, Withheld. *Chickens*.—First, A. C. Lockwood. Second, R. Ashley.

GAME (Brown-breasted Red).—Prize, T. Whittingham. *Chickens*.—First, J. Platt. Second, J. Pedley. Highly Commended, T. Whittingham.

GAME (Any other variety).—First, R. Ashley. Second, J. Wilkinson (Dackwings). Highly Commended, R. Ashley; J. Wilkinson (Dackwing). **COCHIN-CHINA** (Cinnamon or Buff).—First, Withheld. Second, J. Sichel. *Chickens*.—First and Highly Commended, J. Sichel (Buff). Second, C. Layland (Buff).

COCHIN-CHINA (Any other variety).—First and Second, W. Gamon, Chester. *Chickens*.—First and Second, W. Gamon (Partridge).

BRAHMA POOTRA.—First, J. Heath, Nantwich. Second, W. Gamon. *Chickens*.—First and Second, W. Gamon. Extra Second, J. Little. Highly Commended, C. Layland; C. Turner.

POLISH (Any variety).—First, J. Heath (Silver). Second, T. Walsley (Golden-spangled).

HAMBURGERS (Golden-spangled).—First, T. Burgess, Burleydam. Second and Extra Second, S. & R. Ashton.

HAMBURGERS (Silver-spangled).—First, Ashton & Booth. Second, W. Lamb.

HAMBURGERS (Golden-pencilled).—First, W. Lamb. Second, J. Sichel, Extra Second, J. Little.

HAMBURGERS (Silver-pencilled).—Prize, W. Lamb.

GAME BANTAMS.—First, G. & W. Beckett. Second, Bury & Barlow. Highly Commended, W. Griffiths; W. Terry; J. Sichel; H. Goulden; T. Burgess.

BANTAMS (Any other variety).—First, S. & R. Ashton (Black). Second, Mrs. E. T. Belyse (Schright).

CROSSBRED—Chickens.—First, Withheld. Second, J. Little.

ANY OTHER VARIETY.—First, C. Layland. Second, W. Lamb. Highly Commended, J. Sichel; Earl Grosvenor. Commended, Rev. A. O. Pittar.

SELLING CLASS (Any breed).—First, Miss Davies (Dorking). Second, W. Bourne (Brown Red Game). Highly Commended, W. Bourne (Brown Red Game); R. Davies (Black Spanish); Miss Davies (Dorking and Rouen Duck).

TURKEYS.—First, J. P. Campbell. Second, J. Chamberlain. Highly Commended, Mrs. E. H. Tilling.

GOSSINGS.—First, Rev. J. Harrison, LL.D. Second, T. Rigby.

DUCKINGS (Aylesbury).—First, Mrs. M. Hornby. Second, E. H. Tilling.

DUCKINGS (Rouen).—First, Miss Davies. Second, Miss H. Walker. Highly Commended, Miss Davies. Commended, J. Pickering; J. Little.

DUCKS (Any other variety).—First, J. Sichel (Carolinus). Second, J. P. Campbell (Call Ducklings).

PIGEONS.

CARRIERS—Cock.—First, Second, and Highly Commended, W. Gamon. *Hen*.—First and Second, W. Gamon. Highly Commended, F. Graham; W. Gamon. Commended, J. Pitt.

POUTERS—Cock.—First, Second, and Highly Commended, W. Gamon. *Hen*.—First, Second, and Highly Commended, W. Gamon.

TUMBLERS (Almond).—First, J. S. Skidmore. Second, F. Graham. Highly Commended, J. S. Skidmore; A. Eote.

TUMBLERS (Balds or Beards).—First, C. A. Bowles (Blue Beards). Second, F. Graham.

TUMBLERS (Any other variety).—First, F. Graham (Mottled). Second, F. C. Bradley (Kites). Highly Commended, J. S. Skidmore (Kites); J. Grace (Agate).

TUMBLERS (Any variety, not Short-faced).—First, E. J. Baillie (Yellow). Second, W. Benson (Rough-legged Yellow).

DRAGONS.—First, F. C. Bradley. Second, Master C. Gamon. Highly Commended, E. Butterworth; H. Prince; Master C. Gamon.

BARBS (Black).—First and Second, C. A. Bowles.

BARBS (Any other colour).—First and Second, C. A. Bowles.

NUNS.—First and Second, W. Baikes.

FANTAILS.—First and Highly Commended, J. F. Lowe. Second, J. S. Skidmore.

JACOBIANS.—First, C. A. Bowles. Second, F. C. Bradley.

TRUMPETERS (White).—First and Second, Master J. Gamon. Highly Commended, T. B. Bowers; Master J. Gamon.

TRUMPETERS (Any other colour).—First, Second, Highly Commended, and Commended, Master J. Gamon.

OWLS (Foreign).—First, C. A. Bowles. Second, F. Graham.

OWLS (English).—First, A. Eote. Second, C. A. Bowles. Highly Commended, F. Graham.

TURBITS.—First and Second, J. F. Lowe. Highly Commended, J. F. Lowe; H. Prince.

BURTS.—First, C. A. Bowles. Second, F. Graham.

ANSWERS.—First, W. Bourne. Second, T. Walsley.

ANY OTHER VARIETY.—First, J. F. Lowe (Black Lahores). Second, J. S. Skidmore (Spots). Highly Commended, J. F. Lowe (Black Swallows and Yellow Magpies); F. Graham. Commended, C. A. Bowles (Lahores).

Amateur's Cup for greatest number of points in Pigeons awarded to Mr. C. A. Bowles.

The Judges were Mr. Joseph Hindson, Everton, Liverpool, and Mr. John Douglas, Chumler.

NORTH ORMESBY CANARY SHOW.

The second annual Exhibition of this Association was held October 21st. It was a decided improvement on the Show of last year, in the number of entries, variety, and quality of the specimens. There were 207 entries. The Belgians were not numerous, but the prize birds were very superior. The Norwich class prizes were numerously competed for, and all the prize birds were of excellent quality. Variegated Males formed a good class, and the first-prize bird was of rare merit. The Lizards were remarkably good, there not being an inferior bird entered. The Crested were really excellent specimens; Mr. Blakton, whose "Guide to Canary Fanciers" appeared in our columns, took the first and second prizes in the Dark Crested class with two very superior birds. In the Clear Crested class, Mr. Moore, of Northampton, took the first prize with one of the most perfect specimens ever exhibited, the second-prize bird was also a rare bird. The Cinnamon were good, and the prize birds very deserving. In the "Variety class" Mr. Plawman took the first prize with a perfectly marked Belgian; the other birds in this class were also good. In the other classes the competition was close, and the quality excellent.

Annexed is the prize list:—

BELGIAN (Clear Yellow).—First, W. Bulmer, Stockton. Second, J. Robson, Middlesborough. Very Highly Commended, W. Inson, Redfunt.

BELGIAN (Clear Buff).—First and Second, G. Tomlinson, Stockton. Very Highly Commended, W. Bulmer.

NORWICH (Clear Jonque).—First and Very Highly Commended, Irons and Brothers, Northampton. Second, R. Simpson, Whitby.

NORWICH (Clear Buff).—First, Irons & Brothers. Second and Highly Commended, R. Hawman.

NORWICH (Variegated Jonque).—First, G. Moore, Northampton. Second, J. Baxter, Newcastle. Equal Second, R. Hawman.

NORWICH (Variegated Buff).—First, J. Wynn, Northampton. Second, R. Hawman. Very Highly Commended, S. Tomes, Northampton.

GOLDFINCH MOLE (Variegated Buff).—First, R. Hawman. Second, J. Robson.

LIZARD (Golden-spangled).—First, J. Taylor, Middlesborough. Second, J. Stainsby, Darlington. Highly Commended, W. Burniston, Middlesborough.

LIZARD (Silver-spangled).—First, J. Taylor. Second, J. Jackson, Crook. Highly Commended, J. Stainsby.

ANY BREED (Dark Crested).—First and Second, W. Blakston, Sunderland. Highly Commended, G. Moore.

ANY BREED (Clear Crested).—First, G. Moore (Norwich Crested). Second, Irons & Brothers (Norwich Crested). Very Highly Commended, S. Tomes.

CINNAMON (Jonque).—First, Irons & Brothers. Second, W. Bulmer. Very Highly Commended, S. Tomes.

CINNAMON (Buff).—First, G. Moore. Second, W. Cotton. Highly Commended, J. Baxter.

COMMON (Clear Yellow).—First, W. Winter, Guisborough. Second, E. Winter, Guisborough. Very Highly Commended, J. Jackson.

COMMON (Clear Buff).—First, C. Swanson, North Ormesby. Second, J. Ingleby. Highly Commended, J. Yeoman, North Ormesby.

COMMON (Variegated Yellow).—First, R. Hawman. Second, E. Graham, Middlesborough.

COMMON (Variegated Buff).—First, R. Hawman. Second, J. Stevens, Middlesborough-on-Tees.

CANARY (Green).—First, J. Jackson. Second, M. Stelling, Willington, Durham.

ANY OTHER VARIETY.—First, R. Hawman (Variegated Belgian). Second, W. Bulmer (Variegated Belgian).

GOLDFINCH MOLE (Dark).—First, C. Burniston, Tanstall. Second, T. Robinson, Middlesborough. Very Highly Commended, M. Stelling.

GOLDFINCH (Mottled).—First, J. Baxter. Second, J. Taylor. Commended, M. Stelling.

BROWN LINNET (Mottled).—First, W. Bulmer. Second, W. Burniston. Commended, M. Stelling.

ANY OTHER VARIETY OF BRITISH BIRDS.—First, T. Mann (Blackbird). Second, H. Garbutt (Magpie). Very Highly Commended, J. Eggleston (Bullfinch).

CAKE OF CANARIES.—First, J. Yates, Middlesborough. Second, J. Stevens. Very Highly Commended, W. Inson; W. Cotton.

JUDGE.—Mr. J. Chapman, Bishop Auckland.

orange as at once to distinguish it from all other Canaries, and especially from the common Canary, in which, let the colour be as high as it may, there is always a nasty tinge of green peculiarly distasteful to the eye of a fancier. Why the common Canary should find its way into our exhibitions I cannot imagine, unless it be from its having strong local interests. Some men ignore colour altogether, breeding only for markings, and with such these birds find favour. However, I intend next week to say a word on exhibitions and prize schedules, when I shall be able to go into this circumstance more fully.

When a bird is troubled with the "pant," *alias* the "blow," *alias* "asthma," warmth is the grand panacea. Keep your bird warm. Your diet is good.—W. A. B.]

THE BERKSHIRE BEE HIVE.

Fig. 1.

Fig. 2.

Fig. 1 represents the Berkshire bee hive, comprising a store box and two supers, with framed glass sides and back, bottom board, slides, &c. The shutters are withdrawn to show the honeycomb. The supers would each contain about 20 lbs. of honey; by removing a full one and replacing with one empty they admit of unlimited room being given, and so prevent swarming. They have the advantages of glass without its disadvantages; and each super is made to cover half the hive, and so to economise the space.

Fig. 2 is a back view of the Berkshire bee shed for two hives, with two framed doors, and a ventilating door in the gable. One door is open to show the interior.

Fig. 3.

Fig. 3 is a front view of the Berkshire bee shed for three hives. The patterns are rustic and ornamental, being worked with green rods of various shades, interpersed with fir. These sheds have a projecting front, sheltering the bees, and are made to stand very firmly.

THE HONEY HARVEST IN IRELAND AND EN SCOTLAND.

A CORRESPONDENT who writes from the neighbourhood of Manchester says:—"It has been a great year for honey in Ireland as well as in Scotland. One hive came to Liverpool without bees or board, which weighed 9 stones (126 lbs.); and the huge cakes of honeycomb now being carried about for sale in this neighbourhood indicate both large and heavy hives."

VARIETIES OF THE CANARY—DISORDERED BREATHING.

WHAT is the difference between a Norwich Canary and a common Canary? I see at all the best shows the Norwich is put first in the schedules, the Belgian second, and the common third. I have never seen a good show where prizes were offered for all; but I have had birds offered to me for sale said to be real Norwich, but I could never see any difference in them from our ordinary York-shire birds.

Is there any cure for the disease which I believe Canary fanciers term the "pant," but which I think you describe in your little book on Canaries as asthma? I have bred a few for the last ten years, and they have never been troubled with any other complaint. They sit gaping and wheezing, and the pulsation is so strong it can be seen to move the feathers—in fact, the whole body of the bird. What is the cause of it? You state that asthma is caused by the birds hanging in draughts; but it cannot be so in my case, as the birds are in breeding cages with both ends closed, and stand where there is no draught. I give seed in the following proportions—2 lbs. canary, 1 lb. rape, and 1 lb. linseed, with soaked bread, egg, and green food at intervals. It has always come on during the breeding time.—CANARIENSIS.

[There is a very wide difference between a Norwich Canary and an ordinary York-shire bird. The latter is the larger, stronger, and coarser bird of the two, and vastly inferior in colour, which in the Norwich bird is of such a pure shade of

LIGURIANS FOR, AND ANONYMI FROM, THE CAPE OF GOOD HOPE.

RATHER more than two years ago, a gentleman about to leave this country for Cape Town applied to me to supply him with a stock of pure Ligurian bees, packed in such a manner as should enable him to convey them by mail steamer to his new African home with a fair chance of their surviving the voyage. After having in 1862 succeeded in the far more difficult task of transporting Italian bees to the antipodes, I had, of course, every confidence in my ability to pack them for the shorter journey to the Cape of Good Hope, and had, therefore, little fear as to the result, when, on the 10th September, 1866, the Royal Mail Steamer, belonging to the Union Steam Ship Company, took her departure from Plymouth for Africa with decidedly more emigrants on board than usual, seeing that in addition to her ordinary complement of passengers, she conveyed some thousands of the genus *Apis*, probably the first of their species ever exported to that continent, which already possesses more than one indigenous variety of the honey bee.

Although, as I have said, feeling but little anxiety as to the result, I have from time to time given a thought to the fate of

these involuntary little voyagers, and have often wondered whether, after being the first to succeed in introducing the Ligurian variety of honey bee into England, and afterwards in exporting it to Australia, I should also be successful in transmitting it to Africa. These speculations, however, remained in abeyance until February in this year, when a letter reached me from the Cape by which I learned that the Italian stock had reached that colony in safety, but vastly diminished in numbers, nearly five thousand having died. However, after sundry difficulties, they had ultimately been established, and the object which my correspondent had in writing was to obtain from me two more Ligurian stocks, he having unfortunately lost his only pure-bred Italian queen through an accident at a time when there were no drones in the hive.

He also informed me that he had found at Cape Town two native varieties of the honey bee—"one small black, and the other, except in size, the exact counterpart of the Ligurian," and most kindly offered, if I would like to have a stock, to try his hand at packing one, and to send it by steamer to Plymouth. Turning this description over in my mind, I came to the conclusion that the variety which, except in size, was the exact counterpart of the Ligurian, could be no other than my old friend, or, considering the terms on which we eventually parted, I might rather say, enemy, the ferocious Egyptian bee, *Apis fasciata*, which so nearly simulates the Italian variety that the Rev. H. B. Tristram, author of "The Land of Israel," who found it amazingly abundant in Palestine, was misled into declaring that *Apis ligustica* was the common Holy Land insect. This conjecture was confirmed in a subsequent letter from my South African correspondent, wherein he stated that his experience of the "diminutive of the Ligurian" was similar to my own in that they were "very savage." It is certainly not a little singular that identically the same variety of honey bee should be found in the extreme south as exists in the north of Africa and adjoining parts of the Asiatic continent; but as, although separated by so vast a distance, it was but too apparent that there was no amelioration in the pugnacity of their disposition, I respectfully declined to avail myself of the opportunity thus offered of renewing my acquaintance with the "pretty yaller gals," electing rather to transfer my attentions and pay court to the very interesting but anonymous little African "niggers," which my friend had somewhat vaguely described as "small black" bees.

Pending the receipt of farther intelligence, I made an effort to penetrate the incognito of my intended *protégées* by submitting the question to my friend Mr. F. Smith, the distinguished hymenopterist of the British Museum, who, however, could only surmise that "the small black bee possibly is the *A. Adansonii* of Latreille, which I suppose to be synonymous with *A. nigratarum* of St. Fayeau—*A. unicolor* of Latreille, and which M. Gerstaecker considers a variety of *A. mellifica*." I am of course unable to say how far this hypothesis may be correct, but supposing the small black bee of the Cape to be merely a variety of *Apis mellifica*, it is difficult to imagine how the native species or varieties can exist together in the same locality and yet keep themselves distinct. We know with what facility *A. mellifica*, *A. ligustica*, and *A. fasciata* will cross and interbreed with one another, and that this is at least equally the case on the continent of Africa is proved by one of my correspondent's letters, wherein, referring to the breeding of Ligurians in connection with Mr. Köhler's process, he says "it is the one thing required here, where bees of at least two or three kinds are common." These speculations can, however, only be set at rest by the arrival in England of the anonymi themselves, which I now hope may be deferred until next spring, although I have been expecting them during the past two months. My last letter from the Cape, dated the 18th of July, says, "Our native bees do not much like the notion of taking a voyage, at least so it seems, as two or three I have been preparing for you have deserted their boxes entirely, leaving brood in all stages, and betaken themselves to their native mountain wilds. I have four or five, however, now well established, and hope either by next mail, or perhaps a month hence, to be able to pack one or two off in such condition as to reach home alive. So don't be surprised at hearing some Africans knocking at your door."

Although no "Africans" have as yet knocked at my door, it will not now be very long before their own country is again the scene of an Italian invasion, for the Royal Mail steam ship "Saxon," which took her departure from the port of Plymouth early in the morning of the 10th of October, was freighted with two strong bodies of apian Garibaldini in the shape of a couple

of Ligurian stocks, which by the kind offices of a local friend were carefully stowed on board in capital condition, and which, by the time this article appears, will be fast nearing that coast "where Africa's sunny fountains roll down their golden sand."
—A DEVONSHIRE BEE-KEEPER.

OUR LETTER BOX.

KEIGHLEY POULTRY SHOW (T. Dean).—Poultry committees usually announce in the rules of their exhibitions, that they will not be responsible for losses. You have been very unfortunate, but we do not see where blame attaches.

PROMOTING FEATHERING (Lemon Buff).—The food that is most beneficial to fowls when moulting, is that which is at the same time nourishing and cooling. Ground oats mixed with water; these may be given twice every day, say morning and evening; at midday, give some whole barley, with at times a few peas, say once a week; green food at all times, and lettuce is very beneficial. The growth of feathers from the skin of the bird is very much like that of vegetables, root crops, or corn from the earth. Both require moisture. As the sun dries up the earth and prevents growth, so stimulating and heating food causes fever of the skin, and prevents the formation of feather.

GAME COCK'S BEAK BROKEN (Inquirer).—We can hardly understand how your Game cock's beak is broken off up to his nostril, and yet that the lower part projects but the eighth of an inch. The accident is not very important, as it could not have been done to conceal a defect. In close competition it would be sufficient to turn the scale. If, however, the bird in every point were superior, the broken beak would not be important.

SELECTING A WHITE DORKING COCK FOR EXHIBITION (White Dorking).—You should state the weight of the three birds. The first is clearly an unfit bird for exhibition. The second may be heavy enough to carry a slightly crooked breast through. Send us next week the weight of the last two, we can then advise you with confidence. The hens should be square, full in shape and hand, short-legged, five-toed, pure white, and have sharp intelligent heads. There is a contrast between the red faces and white plumage that we do not get in the coloured varieties.

HOUZANS (October).—Red feathers disqualify a Houdan cock hopelessly. Choose the heaviest pen provided all are equally well-shaped. Take those with the black body colour well splashed with white. See that the legs are mottled, and the five toes well defined. They must be well bearded.

WHITE AND BLACK BANTAMS (Idem).—Yellow and white legs are preferred to blue for White Bantams. Black Bantams should have black or blue legs. Single or double combs may be shown in a White pen provided all agree. In Black the double is so much preferred as to be almost essential to success. The Black Bantam must have a white earlobe. It is immaterial for the White.

CHARACTERISTICS OF A LA FLECHE COCK (Irish Subscriber).—The La Fleche cock should be very tall, upright, and heavy. He should have white earlobes, scrupulously black plumage, rich in metallic lustre. The hen should have the same points, and both should have the two-horned comb; and the cock should have the small comb below the principal one, just over the nostrils.

MANAGEMENT OF BUFF COCHIN-CHINAS (A. D.).—You can only make your perches round at top and raised 24 inches from the ground. Many of the birds (being Cochins), will still prefer to roost on the ground. If the ground is kept quite clean they will not suffer from it. We speak from experience. The Light are preferred to the Dark. The desideratum in colour is to get them of a pure lemon. The white feathers on the wing are what are called "menly," and are not desirable. The hackle should not be much darker than the body. The tail feathers will be always a little darker than the others, but nothing is more appreciated both in cocks and pullets than one uniform colour of plumage, without mixture of black or any other colour.

CHEA LLEY (—).—Apply to some farmer in your neighbourhood.

INCUB OR (L. B. Poshell).—Several have been advertised in our Journal, and we cannot recommend one more than the others, never having tested them.

ROBBER BEES (J. Rall).—What are ordinarily called robber bees are those from strong hives which when honey is scarce are continually on the look out for the opportunity of pillaging the stores of others. The insect which you enclose is not a bee, but like the house fly has only two wings, and belongs therefore, to the Dipterous order.

REMOVING BEES—TRANSFERRING BEES (A Subscriber).—The removal of a strong stock of bees by market cart, rail, and cab in the middle of June was rather a risky operation, and considering that you appear to have kept the hive on its floor-board and to have possessed no facilities for affording extra ventilation, we think you were fortunate in effecting it with no greater loss than about a quart of bees and one comb. The check which the stock sustained was, however, sufficient to account for its not swarming. If you wish the bees to take possession of the bar have you should leave but one entrance, and that the one which is at present in use. In April transpose the two hives so as to compel the bees to work from their old entrance but to traverse the empty apartment, which they will probably soon take possession of and rapidly fill with combs. In due time the seat of breeding will be transferred to the bar hive, and then the old one, with its contents, may be taken possession of by the owner. The objections to this apparently easy mode of proceeding are, that the bee-keeper obtains only inferior honey in old combs, whilst so great a proportion of drone combs is liable to be built in the new hive as may seriously interfere with the future prosperity of the stock. We doubt whether your bees have sufficient food to last the winter, but cannot tell without knowing the weight of the hive when empty. Its nett contents should be at least 20 lbs.

POULTRY MARKET.—NOVEMBER 4.

We are tired of recording that there is no trade, and that things look dull and unprofitable, but it is so, and we see little prospect of a change.

WEEKLY CALENDAR.

Day of Month	Day of Week.	NOVEMBER 12—18, 1868.	Average Temperature near London.			Rain in last 41 Years.	Sun Rises.		Sun Sets.		Moon Rises.		Moon Sets.		Moon's Age.	Clock after Sun.		Day of Year

From observations taken near London during the last forty-one years, the average day temperature of the week is 49.0 ; and its night temperature 34.3 . The greatest heat was 63 , on the 12th, 1841 ; and the lowest cold 18 , on the 15th, 1848 . The greatest fall of rain was 1.16 inch.

WHAT TO DO AND WHAT TO AVOID IN THE VINERY.

R. ROBERTS, at page 279, has, in an able and elaborate article, stated his views on Grape-shanking in a manner sufficiently clear and logical to be understood by all interested in the subject.

I agree with Mr. Roberts to the full extent of the opinion he has stated so explicitly, but it is because I wish to go a step further that I enter on the subject which he has opened. I give Mr. Roberts credit in going to the "root of the matter." He has literally bottomed the subject. I am more ambitious, and aspire to a higher view, and will spend an evening's hour at the top of the question ; for, after all, it is there that our hope and interest centre.

Good Vine borders are absolutely necessary for the production of good Grapes, and what constitutes a good border may be clearly gathered from Mr. Roberts's article—viz., material, warm, dry, open, and lasting. Unfortunately these good borders, which have been prepared with so much care and at so much cost, are very capricious in the quality and quantity of the Grapes they were confidently intended to produce. I once heard a gentleman say he had sunk £100 in Vine borders, and had lost both principal and interest in the transaction, although he had waited ten years for a return. Notwithstanding the lapse of this period, he was premature in his judgment: he ultimately, without changing the border, or the varieties of the Vines, obtained good Grapes.

I have seen shanked Grapes cut out by the bushel. Bad border, of course ! A new one made, but still the shanking, like a pestilence, held sway in the house. These Vines are now changed in character—not in variety—but the border is still there, and both are now doing good and satisfactory service.

In these instances, and I think they are not solitary ones, the cause of the mischief was primarily at the top. I believe, indeed, that the roots of the Vines were not in a healthy state, but I hold this to be the effect and not the cause of the unhealthy state of the Vines. Reciprocity of action between root and branch is a law of nature which cannot be broken or checked with impunity. As soon as a diseased root-state occurs, it is followed by diseased branches and fruit ; and as soon as a diseased or imperfect state of branch or leaf development occurs, it is followed by decayed roots. This last fact is sometimes, I think, overlooked, and, as a consequence, a wrong stand point is occasionally taken as the basis of reasoning in diseases of the Vine and other subjects of the vegetable world.

No hesitation need be felt before concluding that much disappointment is felt and expressed as to the disproportion of the value of the Grapes received in return for the outlay incurred in the preparation of borders. Nor is this disappointment confined to amateurs ; on the contrary, many very industrious and worthy gardeners have keenly suffered on this point. They have made borders, and not only invested in them the owner's capital, but their own

good reputation, in the hope of a return commensurate with the outlay, but in place of the bountiful harvest so confidently anticipated, have had to mourn over a comparatively barren and indifferent yield. This is no mere sketch of fancy, but an everyday fact. I grant that a great expenditure of money and labour does not necessarily result in a good and in-every-way suitable border. Many egregious mistakes have been made on this head. I am at the same time unwilling to believe that the majority of borders carefully made are incapable of growing good Grapes, if managed in conjunction with careful and proper top treatment.

I do not seek to depreciate good Vine borders—I advocate the best possible border formation. It is these, combined with the best top treatment, which afford the finest specimens of Grapes ; but it is only by this combination that a Vine border can insure the perfect growth of the Vines. A good border will do much, but will not do all that is required. Vines planted in ordinary garden soil, and receiving sound and careful top treatment, will be more satisfactory than Vines which are planted in a really first-class border, and receive only indifferent top management.

It may reasonably be asked, What constitutes good summer management of a vinery ? Here there is a slight difference of opinion amongst cultivators. It will only be fair, then, if I state my views on the question, and the principles on which they are founded.

A just equilibrium between root and branch—a perfect harmony between supply and demand—is the object to be attained. This is the essence of the whole matter.

To obtain these essentials for the leaves—light and air, the great point to be attended to is to train Vines thinly : 3 feet 6 inches should be the minimum distance apart for the rods, training them 16 inches from the glass, and the eyes or spurs on the rods should not be less than 15 inches apart. These distances will allow for the full development of foliage and its exposure to the light, provided the pinching of laterals is properly attended to. Train the young growths regularly and equidistant, stopping them soon enough to prevent overcrowding. Two or three leaves beyond the bunch may be allowed. As a rule my best fruit is obtained by stopping at the third leaf, and the worst by stopping at the first leaf beyond the bunch. Get these primary leaves in working order as soon as possible by pinching out all axillary productions.

As a rule, this persistent summer pinching is not sufficiently attended to. That letting laterals run by the yard, and cutting them out by the armful, can be beneficial to the Vines I cannot comprehend. Talk of inducing root action, that is doing it with a vengeance, and for what purpose ? I am aware it is not that the roots should decay, yet this is too often the result, and then the border is blamed ! Secure seven or eight properly-developed leaves on every spur, and they may safely be left to govern the roots, which will progress far more naturally and beneficially than by the push-and-crop system, which we are obliged to see so commonly adopted. It was by the adoption of the system above described that the Vines

first noticed at the beginning of my paper, were renovated without making a new border.

I will now glance at the ventilation. I am sure mischief is done in many instances by the careless and lax manner in which this is attended to. An error always to be avoided is the admission of a great amount of external air by the front lights during the early stages of the Vine's growth. Unless means are adopted so that the air entering by the front ventilators is previously rendered warm and moist, it is the safer and better plan to conduct ventilation solely by the top lights, at least during the months of February and March, and part of April—that is, if the Vines are in active growth at this period. One of the most inveterate instances of Grape-shanking which has come under my notice was caused by injudicious ventilation, and, by changing the system adopted, striking and beneficial effects were produced. This instance, and others which I have met with in my practice, have impressed me with an opinion that ill-managed ventilation is a predisposing cause of shanking. In the case referred to the front lights were regularly opened, and left open for hours together during the spring months, and the dry cutting air was suffered to enter uninterruptedly. The consequence of this influx was that the warm, moist, genial air was immediately forced out by the top ventilators, and was replaced by the dry, heavy, and ungenial air admitted. Further, the cold rush of the external air constantly striking the stems of the Vines would seriously check the ascending sap, and not only so, but the very dryness of the air would abstract the moisture from the young shoots and leaves, the surfaces of which would be so much cooled by evaporation as to give them a serious and disastrous check. Here is a combination of evils which must naturally flow from such a system—evils which must and did tell on the Vines during the whole season of their growth. Unless the hand can be held for a length of time to the apertures by which front air is admitted without any feeling of discomfort from cold, it is better to keep them closed, and rely solely on top ventilation. The natural expansion of air on its being heated will always insure its escape, and the weight of the cold external air, as compared to that in the interior, will always insure the descent of the former.

Another important point is to give air early, and increase it gradually as the temperature rises, and not let the house attain its maximum heat, and then have to give an excess of air at once to reduce the heat. In short, let ventilation follow a rise of temperature, instead of a fall of temperature follow an increase of ventilation. As a safety valve it is a good practice to admit a little air at top all night.

As to temperatures, I will begin by saying, Avoid high temperatures, especially by fire heat, and at night. If the border is heated, the Vines are not so susceptible of injury from a rather high temperature. If, however, the border is not artificially heated, keep the house temperature as low as possible consistently with a steady healthy growth. This is doing the best we can to secure an equality of temperature between root and branch—a great desideratum. Let light and temperature always go together. This may be called old advice, but that simply suggests that it is sound by its having stood the test of time.

A sun heat of from 80° to 85° will not be excessive if in conjunction with a good system of ventilation. The solar heat must be economised; therefore as soon as the thermometer shows a falling tendency reduce ventilation, and continue to reduce it until the house can be closed at the heat above named. This economy of sun heat enables us to economise in another quarter—the coal heap, and the Vines will be the better of it. If the maximum day temperature be 80°, a minimum night temperature of 55° will be safe. This applies to the period when the foliage is expanded. Before the leaves reach this stage the temperature must be proportionally lower. Except, perhaps, just at the time when they are setting their berries, I find Black Hamburgs receive no injury by a night temperature of 50°, and one of 60° is quite high enough for a day temperature by fire heat solely. High night temperatures arouse unduly the natural excitability of the Vines. Comparatively low night temperatures cause a cessation of the vital, and assist the secretory functions. Some varieties, as Muscats, require a somewhat higher temperature. When relying solely on fire heat, be up in the morning and have the day temperature up to its figure as soon after daylight as possible. I would specially press this point.

Now, as to moisture, during a high temperature use it liberally, and during a low temperature sparingly. Syringing twice

a-day under all circumstances of temperature is bad practice. On some days damp the paths, walls, &c., half a dozen times, on others scarcely damp at all. In this, as in all other things, exercise thought. The absorbing power of the foliage is greatest in the afternoon, when the house is closed with a good sun heat. This is the time for feeding. Give ammonia freely. The Vines enjoy it; insects detest it. Water the paths, pipes, flues, &c., with water, in which guano is dissolved at the rate of 2 ozs. to the gallon. More than this will not hurt them, but this is a safe proportion, and will not fail to act beneficially; but use it only when the leaves are expanded, and not before.

The last, but not least important is cleanliness. Uncleanliness, from whatever cause arising, is entirely subversive of success in Grape-growing, and renders all previous care and attention of little or no effect. The foliage must be kept free from dirt and insects. To guard against the former, I never allow any dust to rise in sweeping the paths of the house, &c. This is a trifle of some import. Neither do I syringe, so that I avoid any sediment and incrustation from the water. Red spider I never see; any other insect seldom. In some localities syringing may be necessary to cleanliness. I do not find it so here. I know something of the atmosphere of a manufacturing city; good washings with the syringe and pure rain water are there occasionally requisites. Use this and any other means at command that may be needed to ensure cleanliness. This treatment will give fine, dark green, leathery foliage, which will bring up the best elements of the border, and render them fit for appropriation by the Vines. Injudicious top management will negative the best effects of the best border that ever was made.

And, now, do I practise the system described? Yes, except on one point; and though I have an outside border just 10 feet wide, and the roots a foot and more beneath the surface, I obtain a satisfactory yield of Grapes, and have next to no shanked berries. I have for the border in winter wooden shutters, which I highly recommend; yet, notwithstanding, were I to allow the laterals to grow, and cut them out by the armful, instead of being able to put those pinched from an entire house in my pocket, or were I to allow the dry chilling air to cut or dry the young growth, or otherwise allow the Vines to be subjected to any course of unnatural treatment, I should expect—and I know from experience that my expectations would be realised—shanked Grapes in quantity.

But the exceptional point. Well, I am a servant. My employer is explicit in his requirements, and my duty is plain. Two or three ordinary-sized bunches are more useful than one large one. With a rather limited expanse of glass devoted to Vines, my object is to make the Grape season as long as possible. We cannot easily cut half a bunch of Grapes, or a bunch and a half; but by having a number of different-sized bunches I can meet daily demands to a nicety. My Vines, then, are not all 3 feet 6 inches apart; some are, and they give the best Grapes, but as a whole they answer their purpose so well, that I do not feel justified in recommending a change. But were I required to grow large individual bunches, I should at once thin the rods. I should then bare the roots, and put on a few inches of light turfy loam and bruised charcoal, and draw the roots upwards by covering the border with heating material to accomplish my object. This treatment will keep Vines in vigour and fruitfulness for many years.

I will conclude my evening's exercise by quoting and placing together a maxim from Mr. Roberts's article and one from my own:—"Afford the Vines a warm, dry, and open soil, and shanking will be less frequently seen." "Devote as much care, attention, and study to the house management of Vines as is given to border formation, and inferior and shanked houses of Grapes will be far less common."—J. W.

[We have seen specimens of the Black Hamburg Grapes and the foliage of the Vines obtained by our correspondent—they were all that can be desired in Vine culture.—Eds.]

A FIGHT WITH A FLUE.

ONE night in November, some years ago, I was sitting very comfortably before a warm fire in my study, talking with a younger brother, an engineer in London, who had come down to spend a few days with me, when my servant came in to say that John wished to speak to me. It was after nine o'clock, and I wondered very much what John wanted; so I went out at once to see him, and was thus greeted.

"Please sir, I am sorry to say I can't get the fire to go in

the span-roof." This "span-roof" was a greenhouse I had just finished. Everything belonging to it had been planned by myself after much consultation with many friends skilled in horticulture, and I felt very proud of it, thinking I had built a very perfect little house at a moderate cost. I particularly rejoiced in the flue, which went up the centre of the house and returned over itself, thus forming a neat pathway, while the heating apparatus was nearly hidden from sight, and consequently took up no valuable room in my little "place." About two thousand cuttings of *Pelargoniums* struck in boxes were placed in this house; and as it had been cold and cloudy all day I rather expected a frost at night, and had given John directions to light a fire. This John was a young man of eighteen or nineteen, and had only just come to me. I did not like to be very round with him on so short an acquaintance, but I asked him rather sharply why he had not come to tell me sooner.

His reply was, "Please sir, I heard 'em say Mr. Tom was down from London, and I did not like to trouble you, for I thought I could make the fire go; but I have lighted it ever so many times, sir, and it won't."

I said, "I don't think you've tried the right way, for old Walker put a fire in the house several nights before you came." (But "old Walker," who managed my garden when I happened to have no regular man, had told me to my great chagrin that "there seemed to be no draw at all in that new-fangled flue, and I had better have it altered before winter, or I should be certain to have the frost in the house and have all my plants killed.") John replied, "I have tried all I know, sir, and it won't burn."

I said, "What sort of a night is it? Have you any dry sticks?" John answered that it looked likely for rain, but might clear off and freeze when the moon got up. He had burnt all his dry sticks and shavings, and had not one left.

This was a nuisance, but John was already a favourite with the women of the establishment, and to my surprise the housemaid offered part of her stock of firewood. Armed with this and a shovelful of red-hot cinders from the kitchen fire, we marched to the greenhouse and tried again to light a fire. As I went down into the firehole John told me to be careful, for the fire "popped back;" and so it did, nearly singeing me badly, and filling the pit with flame and smoke. But it was of no use; the fire would not burn, and soon died out as before. We gave it up for that night, and I directed John to have a great quantity of wood dried as soon as possible in the morning, and we would begin early and have a day at it if necessary. I went to bed, but not to sleep, for I was very anxious about my plants, and got up many times in the night to look out of the window. Fortunately it did not freeze, and towards morning began to rain steadily and heavily.

Well, then, after breakfast next morning I set off with my brother to attack the flue, and John having provided a tremendous lot of dry firewood, we commenced operations. I tried every dodge that I could possibly think of, but the kindling was all done before I could raise a fire. I felt beaten with my own invention, and having sent John to the wheelwright's shop for "a few more shavings," I turned to my brother and asked him how it was. I had bragged rather largely of my house and the skillful way in which the flue was built, and I saw he smiled when he replied, "I think you are like a great many more I have heard of; you have contrived a very wonderful machine, but it is quite beyond your power to work it. Neither you nor your man knows anything at all about what you are trying to do. What will you give me to put you both right?"

"Anything you like," said I; "but I am afraid we shall have to get the flue altered."

"I think not," said my brother; "but we shall see. You fetch an armful of dry straw from the stable while I crack up some of this coal."

Putting on John's slop my brother set to work lustily, and I brought him some dry straw. He opened a small soot-door at the bottom of the chimney, and put in a wisp of straw and another larger wisp in the furnace, took out a match and lit a piece of paper, with which he set fire to the straw in the chimney, and when that was fairly going he shut up the soot-door and lighted the straw in the furnace below. How it roared away to our great satisfaction, and when the straw had caught fire all over he threw on lightly a shovelful of slack, closed the top door of the furnace, and we left it about half an hour. When we returned it was all in a glow. My brother pushed the fire all back, and put on a lot of coal in front, and closed

both doors of the furnace, leaving a little draught on in the bottom door. This he did because the day was wet and foggy, but on a bright day or night I find the fire burns away quite fast enough without leaving any air on there at all.

I have no trouble now, and often light all my other greenhouse fires from this furnace, because I can so easily and so quickly obtain a good stock of fire there. If any of your readers are troubled with a flue which does not draw well, let them put a small door at the bottom of the upright chimney, and burn a wisp of straw there when they light the fire in the furnace. They will soon have fire enough.

I may add that this plan has been adopted in our parish church with Mitchell's patent hypocast system of heating, and answers admirably. When this method of heating our church was first adopted the fires were very refractory in dull weather; and although it is said, "Where there is smoke there is fire," it was much more common for us to see a church full of smoke than to feel any good effects of a fire. *Nous avons changé tout cela*; and wet or dry, wind north or south, our sexton can always ensure us good fires and a warm church free from smoke any cold Sunday in winter.—A. R. L.

VARIEGATED ZONAL PELARGONIUMS.

HAVING promised in my last article on bedding *Pelargoniums* to send you some further remarks on the Variegated section of Zonal *Pelargoniums*, I do so now, not as the result of a particular set of trial beds, but as the result of general personal observation, in my own garden, in my friends' gardens, or in the public gardens which I have seen during the last two years. One difficulty in treating of the subject, is to separate the varieties properly into their different sections; and without endeavouring to lay down any very fixed rules, I shall divide them—1st, into the Gold-edged and Gold Selfs, including both Tricolor and Bicolor. 2nd, Silver-edged, Tricolor and Bicolor. 3rd, Bronze-zoned.

To begin then with the GOLD-EDGED section, we will take the Tricolors first, of which Mrs. Pollock is the type. Their names now are legion, and many of them differ only by the slightest shade, either in breadth of zone, or habit of growth, or colour of the leaf-margin, &c., and one of the great difficulties which we have at present, and which I foresee looms still more heavily in the future, is to reduce the number of different sorts, and to do away with all those which are not *bona fide* improvements on existing varieties.

Many of the best of the Tricolors, in point of colour, as Mrs. Allen, Lucy Grieve, &c., will only do as pot plants, and there are very few as yet in my opinion, which surpass Mrs. Pollock as bedders. Those which I think can be safely recommended are Lady Cullum, Sophia Dumaresque, Sophia Cusack, Countess of Tyrconnel, Edwina Fitzpatrick, and Sunset. The first three are, if anything, an improvement on Mrs. Pollock. The Countess of Tyrconnel is not easily distinguished from Sophia Dumaresque, and both have rather an upright habit of growth. Sophia Dumaresque has a good vigorous habit, but I think both for pot plants and bedding purposes there is not one better than Lady Cullum, the breadth of the dark zone giving a very fine contrast to the yellow belting, and the flame colour in my opinion being brighter than in any other variety.

There are several others of which I have only seen a few plants either at exhibitions or in nursery gardens, &c., and of these, Smith's (of Dulwich) Sunray, Retaliator, Coronet, Defiance, and Souvenir de Sir Joseph Paxton; and Carter's Prince and Princess of Wales, Ettie Beale, and Dr. Livingstone, seem to be very promising. Especially so is Retaliator, which was shown in fine colour at Leicester, and seems to have a vigorous habit. Ettie Beale, though fine in colouring, will, I am afraid, be only a pot plant. Miss Watson has, in my opinion, been much overrated.

Here I may make a general remark, that the effect of Tricolor *Pelargoniums* for bedding is by no means commensurate with the beauty of the plants as individual specimens. Their effect in the distance is not so good as the older plain Gold-edged kinds, and I believe that many of our finest and most effective pot plants will eventually prove but second-rate bedders. The fact is, the contrasts of colouring are contained in the leaves themselves. Gold, red, green, and dark brown, are so mixed together that it is difficult to place another band of colour alongside, which contrasts well with them, and large masses of Mrs. Pollock, and *Pelargoniums* of its type, are by no means effective in beds. The proper place for these varieties in the

flower garden is in beds which are to be seen near to the eye, or in lines close to the windows of the house, or as edgings to vases on terraces; and the best contrasts, in my opinion, are white-leaved plants, especially *Poa trivialis*, and *Dactylis elegans variegata*, or small plants of *Centaurea*. Blue *Lobelia*, again, does very well, especially the dwarf kinds—*pumila elegans* and its varieties; but, unfortunately, there are very few kinds of *Lobelia* that last long enough, and when the flower goes off, there is nothing which looks much worse. I am, however, trespassing on another subject which ought to be treated by itself.

I will now pass on to the Gold-edged Bicolor varieties. Of these there are happily not so many, the best being Golden Chain, Gold Pheasant, Crystal Palace Gem, Cloth of Gold, Golden Fleece, and to these I will add at once, the GOLD SELFS, Gold Leaf, and Pillar of Gold.

Golden Chain is still with me the best of the Gold-edged varieties; it will not thrive in cold or clay soils, and ought to have some well-decayed farmyard manure or leaf soil forked into the soil for the plants at bedding-out time. Crystal Palace Gem, Cloth of Gold, and Golden Fleece, are, as a rule, too green, but are good wet-weather and autumn plants. Gold Pheasant has too upright a habit, but the colour is good. I forgot to mention *Stella sulphurea marginata*, which I think is very promising; but of all the plants in this section I like Pillar of Gold, sent out by Mr. C. Turner, of Slough, the best; it is far the most golden of any I have yet seen, both in-doors and out. The leaf when dying off turns to a lighter yellow, which enhances the effect of the plant, instead of burning-up at the edges, as many kinds do, and I venture to prophesy for it a long and prosperous career. In point of habit it seems to be all that can be desired, with abundance of foliage. Gold Leaf, the other Gold Self I mentioned, has not constitution enough.

I will next take the SILVER-EDGED section, commencing with the Tricolors—viz., Beauty of Guestwick, Italia Unita, Burning Bush, Picturata, Countess, Queen's Favourite, Waverley, &c. Many of these have not sufficient strength of habit for bedding purposes, and I have seen none I think so good as Italia Unita. Beauty of Guestwick has a more vigorous habit than most of them. Burning Bush is still as good as any for dwarf front edgings, &c.

Among the Bicolors come most of our old sorts: Alma, Bijou, Brilliant, Mrs. Lennox, Countess of Warwick, Variegated Nosegay (Beaton's), Flower of the Day, Flower of Spring, and Jane. Of these I would place foremost Flower of the Spring, as certainly the best both as a pot plant for conservatory decoration, and also for bedding purposes. Bijou, which is one of the whitest, has a very bad upright habit of growth, hardly ever throwing out a side branch, unless pinched-in. Jane is a very good variety, especially for Self beds, having a very free-growing branching habit, and the leaf-margin distinct and good.

Brilliant I only name to condemn. It is good as a free-flowerer, but, as in the case of Mrs. Benyon among the Gold Tricolors, its flowering habit is rather a demerit than a merit, as nearly all variegated-leaved plants are better with their flowers cut off. Flower of the Day is, like Bijou, too leggy.

Alma is still one of the best, especially in large plants. Mrs. Lennox has a very pure white edge, and is very good in light rich soil. Countess of Warwick has so dark a zone sometimes that it might almost be called a Tricolor, though in that case Lady Cullum, Mrs. Pollock, &c., ought to be called Quadricolor; it is a good plant for ribbon borders. Another old sort which I had almost neglected, Mountain of Light, is still very good for front edgings, having a neat, dwarf habit and a pure white margin.

This brings me to the last, the BRONZE section, of which I must confess I have not had much experience of my own. The most effective that I have seen bedded is Bronze Queen, the habit being exceedingly compact, and the foliage very dense. Among the best are Beauty of Oulton, Beauty of Ribblesdale, Beauty of Calcedale, Egyptian Queen, Perilla, Model, Luna, and three which Messrs. Smith, of Dulwich, exhibited at Leicester, Criterion, Plutus, and Sybil.

As a general rule, I have been disappointed with the effect of the Bronzes when bedded out. Many of them are very beautiful as pot plants, and they will be very good as garden decorations for all places where they can be brought near the eye; but the same remark I think applies to these as to the Tricolors, where distant effect is required. It will be some time before a definite fiat will be pronounced upon them, but I think it will be found eventually, that both the Bronzes and Tricolors will be best used as panels in contrast with other

colours, like gems, or in small circular beds as edgings or centres along with other ornamental-foliaged plants.

There are some other Variegated sorts I have omitted, as Mangles's, which is still a most valuable sort, and one of the most effective beds I have seen this year was at Lilangattock, near Abergavenny—blue *Lobelia* and Mangles's, plant for plant, in a circular bed about 8 feet in diameter, the small pink flowers of Mangles's being allowed to remain on.

L'Elegante is a very promising Variegated Ivy-leaved Pelargonium, and will be valuable as edgings to raised beds and baskets, and also for hanging baskets for conservatories. The old sweet-scented Lady Plymouth is also a useful plant, when it can be placed in a position where it may be allowed to grow as much as it likes, as it is of much too strong a growth to mix with other bedding plants.

I must now conclude these remarks, as it is my intention to trespass upon your space again another time, with a paper on the winter management of Pelargoniums; what most persons will, I am afraid, consider a trite subject, but concerning which there is yet something to be said.—C. P. PEACH.

CAN BEET BE HAD AS AN EARLY BEDDER?

I BEG to thank Mr. Mason for his courteous reply in page 323 to my inquiries respecting certain occupants of the flower garden, and seeing we agree in opinion about the merits of Tricolor Pelargoniums for that purpose, I am not surprised we differ in some degree about that of Beet for the same purpose. My wish was to ascertain whether its appearance before August 1st was such as to entitle it to a place in a flower garden that was to look well before that time. Not having grown it here for decorative purposes, I could only judge of what it might have been by the appearance of the kitchen-garden crop of the same plant at that time, and this was merely coming into condition at the end of July. Early sowing, no doubt, might have rendered Beet intended for decorative purposes more forward; but unless the plant can take its proper place along with *Calceolarias* and Pelargoniums by the 1st of July, or even earlier than that, it will not answer my purpose. The question is, Can it be made to do this, and afterwards continue in good condition throughout the season? I fear not. Hitherto I have been obliged to depend on Perilla for early and late work, and I would willingly exchange it for Beet if the latter could be coaxed into useful condition so early in the year, and would yet continue to do good service as late as at present. The fine colour and graceful habit of this plant place it much higher in the scale of merit than any of its compeers, Iresine, when good, excepted; but the difficulty of obtaining it early enough and preventing its running to seed, has with me been a great drawback to its use; but in places where appearance after the middle of August is of more consequence than before that time, a good variety of ornamental Beet may be of great service. With me, however, it ought to come into use in June and July. I again ask if the same plants can be made to do duty so early, and yet look well in October?—J. ROBSON.

TRUE SCOTCH KALE.

I ENCLOSE a small packet of the true "Lang Scotch Kale" seed, which is not now to be had genuine in the seed shops, and if sown now (June 17), in your southern clime you may have a next-winter supply of greens from it.

It is the "Lang Kale" of Robbie Burns, also known by the name of Kilmaurs Kale, from Kilmaurs, near Kilmarnock, once the Birmingham of Scotland, having been no less famed for its Kale seed than for its "whittles" or clasp knives, and "lang Kale gullies." Hence the old Ayrshire saying that a person of acute mind or smart habits was "as sharp as a Kilmaurs whittle." The clank of the whittlemaker's hammer has, however, been long silent in Kilmaurs, which is now a curious old country village, and the Lang Kale are no more seen in its Kale yards, their place being usurped by the finer-looking but inferior-flavoured German Greens; but they are still to be met with in the high moorlands of the county, where they are retained and esteemed for their hardiness as well as excellence by the shepherds and other thinly-scattered cottagers, most of whom grow their own Kale seed.

Similar but somewhat shorter-growing races of Kale are also still grown in the Western Isles, as well as among the central Grampians, such as the Tallybeagles Kale of Perthshire, &c.

named from the plants being largely grown by small farmers in that upland district, and sent north in spring for sale in the Highland markets.

The Kilmaurs Kale forms the best of Hallowe'en stocks, being "muckle anes and straight anes," with reddish bark and reddish leaf-veins, while the "flat of the blades" is of a reddish green colour, and these should be plane, or only very slightly curled.—WILLIAM GORME.

SUBTROPICAL GARDENING.

How delightful it must be for those who live in the neighbourhood of Battersea Park, who can at any moment enjoy the magnificence and the luxuriance of the tropics! To have a bit of Brazilian scenery in the neighbourhood of London, and that in the open air, is really wonderful. We remember something of Pine Apples in the open air at Bicton, growing, so we were told, like Cabbages: but really the description in the *Journal of the tropical*—I beg pardon, subtropical—gardening in Battersea Park, is enough to make us who live in the northern parts of the kingdom go delirious. How I could wish all persons who feel an interest in this matter, and most gardeners should do, to coolly argue the extent of its practicability and application, and in what parts of the kingdom it is likely to succeed, and where it would be folly to attempt it. These are more important operations than many are aware of. Unreflecting people, who are, perhaps, whirled from Battersea Park into the North of England in a few hours, forget that the climate of Battersea Park does not travel with them; and no doubt many an intelligent worthy man will have the cold water of "Yon should see Battersea Park" thrown in his face. And while the system may be lauded by enthusiastic visionaries on one hand, and opposed by the matter-of-fact man on the other, let the question be set at rest by a little good-natured agitation. Honour to the man who has the sense or the boldness to deviate from the beaten track; and the testing of the capacities of plants for given purposes is very commendable, especially where people are honest enough to record failures.

Most gardeners know something of the marvellous change in, and effect produced by, overgrown specimens of stove plants turned out to play a false character for a brief season and die. There may be something false in thus giving these vegetable worthies a character quite unnatural to them; it is perhaps the most rational way of getting rid of our ponderous Cycas, overgrown Brugmansias, and lumbering Agaves; still the thoughts of these fine things being brought out to perish create an idea similar to seeing a great personage brought out to execution. Hence a question arises, Is tropical or subtropical gardening compatible with English climate and English scenery?

Now I solicit information. Would the gentleman who has written the description of Battersea Park tell me what is *Sedum glaucum* like "charming little buttons"? I am a great lover of *Sedums* and *Saxifrages*, and should much like to make the acquaintance of any *Sedum* compact as a button. I have noticed several allusions to *Sedum* where evidently *Sempervivums* were meant. Are they amalgamated? Again (I am quoting from page 209 of the *Journal*), "and *Sedum ochroleucum* formed very pretty dense tufts, those of the last-named in particular being almost like small berries." Dense tufts like small berries! I am much interested in these little alpine creatures, but cannot at all understand the above. *Sedum glaucum* is a British plant, pretty enough in its place, but of a loose straggling nature, not at all like a button; and *S. ochroleucum* is also a very straggling plant. Please to set us right on these little matters.—T. WILLIAMS, *Bath Lodge, Ormskirk*.

[The writer of the above is right in suggesting a cautious line of procedure in matters connected with subtropical gardening, and especially in the north; and that gardeners should "coolly argue the extent of its practicability and application, and in what parts of the kingdom it is likely to succeed, and where it would be folly to attempt it." The descriptions in the report on Battersea Park were faithfully given, and the fancied error, for it is only fancied, as regards *Sedums* and *Saxifrages*, and *Sempervivums*, does not affect the matter of fact, that those plants figured conspicuously in the arrangement described. The general ignorance of subtropical decoration is permeated by an idea which has no foundation in truth, that great losses accompany it, whereas 1 per cent. covers at Battersea Park the losses of "these vegetable worthies," such as "Cycas, overgrown Brugmansias, and lumbering Agaves," and plants of many other genera, and they are used year after

year successively. It should be known, however, that this does not apply to annuals, as many *Solanums*, nor to *Iticinus*, *Wigandia*, *Ferdinandia*, and a variety of softwooded kinds, that are raised annually from cuttings, or from seeds in the spring, and are allowed to remain until destroyed by frost. Subtropical gardening is as successfully practised at Cliveden as at Battersea, on a smaller scale, and at other places round London, and also at Aston Park, Birmingham. These are hints which we throw out for our friends in the north, in the hope that if their operations are directed by discretion, and a thorough knowledge of the subject, at least many failures will be prevented, and that success will, to a considerable extent, attend their efforts, and enable them ultimately to enjoy, in their own gardens, the magnificence and luxuriance of tropical vegetation.]

ROYAL HORTICULTURAL SOCIETY.

THE following arrangements have been made by the Royal Horticultural Society for their Exhibitions and Meetings next year:—

March 13th, Show of Hyacinths and Spring Flowers. At this meeting prizes to the amount of nearly £50, offered by the principal bulb-growers in Holland, will be competed for; and Mr. William Paul, of Waltham Cross, will continue his exhibition of spring-flowering plants. April 17th, Show of Roses and Spring Flowers. May 8th, Show of Early Azaleas and Spring Flowers. During this month a Show of Pelargoniums will be held, at which subscription prizes by the growers of these plants will be competed for. June 2nd and 3rd, Grand Summer Flower Show. June 15th, Special Prize Show. June 29th, Great Rose Show. The National Rose Show is incorporated with this Exhibition. A Grand Summer Exhibition of Flowering Plants and Fruits will be held at Manchester in July, at the same time as, and adjoining, the Royal Agricultural Society's Show.

The Fruit and Floral, and General Meetings for the election of Fellows, &c., will take place as follows—viz., January 19th; February 16th; November 16th; and December 21st; and on the first and third Tuesday in each month from March to October inclusive.

PETUNIAS APPEARING THOUGH UNSOWN.

This season we have seen what I presume would be considered a horticultural rarity. In the garden attached to my house, which is 300 feet above the level of the sea, and in a most open and exposed situation, Petunias have sprung up spontaneously in the open ground in large quantities, and some very beautiful ones were among the number; also, on a heap of clay and rubbish several came up, but how the seeds reached the place at all is a mystery. During my residence of two years I have been making the flower garden, in which no such thing as a Petunia had ever been; added to this the house and grounds are thoroughly detached, and how the seeds came to be in the heap of clay and rubbish especially, is inexplicable. Added to this, the earth for the border in the garden in which they were also found, was taken from a pasture and some inches below the surface soil. Your comments on the above will much oblige.—JAMES G. DANGAR, *Vicar, Boyton, Cornwall*.

[Years ago, perhaps either Petunias seeded in your or some other garden, and were thrown on to the manure heap, and the manure was dug into the soil of your garden, or washed by the rains into the soil of the pasture; and when once seeds are buried so deeply in the soil as to be prevented germinating they often keep sound for many years, and vegetate when by any means they are brought nearer to the surface, and, consequently, within the influence of the requisite amount of warmth and air. Seeds in the Egyptian mummy cases, and the seeds of Charlock in soil raised from great depths, Celery seed ten years old, and other instances are within our knowledge, demonstrating how long seeds retain vitality.—EDS.]

STOKE NEWINGTON CHRYSANTHEMUM SHOW.

THIS was held on the 10th and 11th inst. in the Luxembourg Hall, near Dalston Junction, a place very convenient of access from nearly all parts of London. The display was, as usual, excellent, and very effectively arranged; the specimen plants being placed all round the room, and the cent blooms on the centre table forming a bordering to a fine collection of fruit exhibited by Mr. James, of the Rochester Castle, Stoke Newington, part of which was English-grown, consisting of Apples, Pears, Grapes, Medlars, Walnuts, &c., and another part of Apples and Pears grown by Mr. Langlois in Jersey, and many of

them very remarkable for size and beauty. At the end of the room facing the entrance, Mr. F. Waltz, of Walthamstow, exhibited a collection of neatly arranged bouquets of dried flowers; at the other, Mr. Smith, florist, Kingsland Road, a number of bouquets and a pyramid of fruits surmounted by a Pine Apple; whilst in the centre Mr. George, gardener to Miss Nicholson, Stamford Hill, had a tastefully arranged table decoration, for which he received a first prize. Prizes were also awarded to several of the other exhibitors just referred to.

For six plants of *Chrysanthemums* Mr. Forsyth was first with beautifully grown and flowered specimens of Christine, Golden Christine, Annie Salter, Prince of Wales, Dr. Sharpe, rich crimson, and Mrs. George Rundle, pure white. Mr. Drain, De Beauvoir Town, who was second, had very good specimens of Beverley, Prince Albert, Mrs. G. Randle, Dr. Sharpe, and Prince of Wales. With three plants the same exhibitors occupied the same relative positions; Mr. Forsyth being first with Dr. Sharpe, Mrs. G. Randle, and Golden Christine, and Mr. Drain second with Prince Albert, Golden Christine, and Golden Beverley.

In the class for six Pompons Mr. Batchelor, who took the first prize, had the Golden, Lilac, White, and Brown forms of *Cedo Nulli* in fine condition, and the richly coloured *Sainte Thais*. Mr. Forsyth, to whom the second prize was awarded, had fine examples of *Anore Boreale* and the different forms of *Cedo Nulli*, but his had not all come into full bloom. For three, Mr. Drain was first, Mr. Batchelor second. Standard Pompons were very fine, especially those from Mr. Beattie, gardener to J. Watson, Esq., Stamford Hill, who had plants with flattish heads about 28 inches in diameter, and masses of bloom. The most noticeable were *Cedo Nulli*, Brown *Cedo Nulli*, Golden *Cedo Nulli*, *Durandet*, and *Calliope*, the last very showy, being of a ruby colour. Mr. Forsyth was second with some of the above, and Lilac *Cedo Nulli* very fine; and Mr. Howe, Shacklewell, third, with White *Trevenna*, *Antonius*, yellow *Anemone*-flowered, and others also very good.

Collections of large-flowering and Pompon varieties were also exhibited in an extra class by Mr. James, Mr. Forsyth, and Mr. Batchelor, to each of whom prizes were awarded, also by Mr. Goodenough, who took a special prize offered by Mr. Crute. Among these were finely-bloomed plants of *Bronze Jardin des Plantes*, *Lady Harding*, Mrs. G. Randle, Prince of Wales, Dr. Sharpe, and the splendid white large *Anemone*-flowered *Lady Margaret*, also *Bob* and several other Pompons. The number of cut blooms exhibited was, perhaps, scarcely so great as last year, but the quality of a large proportion was most satisfactory.

The best stand of twenty-four came from Mr. Row, Roehampton, and consisted of *Lady Slade*, Mrs. Halliburton, *Aimée Ferrière*, *For mosum luteum*, *Nil Desperandum*, *For mosum album*, *Oliver Cromwell*, *Aureum multiflorum*, *Venus*, very large; *Yellow Perfection*, *Marchal Durac*, Princess of Wales, 44 inches in diameter; *John Salter*, very fine; *Lady Harding*, *Gloria Mundi*, Mrs. Sharpe, White Globe, an immense flower, quite 5 inches in diameter; *Queen of England*, also of very large size; *Empress Eugénie*; *Prince of Wales* and *Empress of India*, both magnificent; *Jardin des Plantes*, *Beauty*, and *Prince Alfred*, quite 11 inches across. Mr. Morgan, of Plymouth, was second with fine blooms of *Empress of India*, *John Salter*, *Oliver Cromwell*, *Prince of Wales*, *Princess Beatrice*, Mrs. George Rundle, and several other varieties already named. Mr. Howe was third, and Mr. Slade fourth. *Prince* and *Princess of Wales*, *Hereward*, and several others in these stands were fine.

The best twelve blooms came from Mr. Morgan, and the second best from Mr. Row; Mr. Wheldale, of Holloway, and Mr. James being third and fourth. In Class 9, also for twelve blooms, Mr. Goodenough, Mr. Shield, Mr. Beadle, and Mr. Heard took prizes in the order named. Among the varieties shown in these classes were good examples of *Empress of India*, *John Salter*, *Prince* and *Princess of Wales*, *Prince Alfred*, *Princess Beatrice*, *White Globe*, &c. For six, Mr. Wheldale was first, Mr. Morgan second, Mr. Heale third, and Mr. Row fourth. In another class for the same number of varieties, the prizes went to Mr. Shield, Mr. Beadle, Mr. Heale, and Mr. Goodenough. The prizes in the "maiden" classes went to Mr. Beattie, Stamford Hill, and Mr. Baldwin, Kingsland.

Of *Anemone*-flowered varieties, both Mr. Row and Mr. Howe exhibited beautiful examples, the former being first and the latter second. *Lady Margaret*, white, *Fleur de Marie*, *Gluck*, *Prince of Anemones*, and *George Sand* were especially fine. For thirty-six *Anemone*-flowered Pompons, Mr. Howe and Mr. Row exchanged positions, both, however, having remarkably fine examples of these varieties.

Mr. Morgan exhibited several seedlings. Mr. Crute sent fine blooms of *Red Dragon* and *Daimio*, two of the new Japanese varieties, large and extremely showy. The rosy lilac colour of the latter kind is very pleasing.

GOLD AND BRONZE PELARGONIUMS.

WHILE I readily admit the desirability of having round flat leaves in bedding *Pelargoniums*, I ask, Are they altogether such indispensable conditions to render a variety first-class for bedding, as Mr. Cannell would have people suppose? I say that they are not: for instance, his Ivy-leaved Duke of Edinburgh is first-class as a bedding plant, while we all know that it is very far from having a regular outline. Again, his com-

parison of Kentish Hero with *Perilla* is singularly at fault, for no two varieties can possibly be more distinct from each other than these in the most essential particulars—namely, coloration of the leaf, *Perilla* being a green-leaved variety, and Kentish Hero a bright golden-leaved one, with bright red zones; and till we obtain a variety as effective as it proves to be, with round flat leaves, I must coincide with the opinion expressed on at least two occasions this season by the judges at Chiswick, that for effectiveness as a bedder it is the best at present in commerce.—W. B. G.

PRESENTATION TO MR. DAVID THOMSON, OF ARCHERFIELD.

ON Thursday last some of the friends and well-wishers of Mr. David Thomson, head gardener to the Right Hon. R. C. N. Hamilton, Archerfield, embraced the occasion of his leaving his present situation for the service of the Duke of Buccleuch at Drumlanrig, to show the high esteem in which he has long been held by them. At one o'clock, a deputation from the subscribers to a very beautiful testimonial assembled in the Dirleton Castle Inn, for the purpose of presenting it in public to Mr. Thomson. Among those present were Mr. Hope, Pentonbarns, and many other eminent agriculturists of East Lothian, and the Rev. Mr. Howieson, Dirleton; horticulture being represented by Mr. Downie, of Downie & Laird, Edinburgh; Mr. Mitchell, of Lamont & Mitchell, Edinburgh; Councillor Lewis, Edinburgh; Mr. Thomson, Dalkeith; Mr. Lees, Tynninghame Gardens; Mr. Balden, Niddry House, &c.

Mr. Hope, who presided, said the present meeting was a deputation from the numerous personal friends and professional admirers of Mr. Thomson, who, before he left this part of the country, desired to present him with a small but tangible token of their high esteem for his personal character, of their great admiration for his professional and scientific attainments, as evidenced in his published works, and of their appreciation of the success he had attained in the highest walks of practical gardening. (Applause). In regard to Mr. Thomson's literary attainments, he (Mr. Hope) believed that the merits of his works had been cordially acknowledged by his professional brethren, while, to amateurs like himself, he had found them of the greatest use; and he had no doubt as they were better known they would be more and more admired. Their style was invariably terse and clear, while his felicitous choice of words was only equalled by the correctness of the principles and the practice which they inculcated. It was now upwards of ten years since Mr. Thomson came to the parish; and year after year as his friends became better acquainted with him, the more their esteem for him increased. (Applause). In regard to Dirleton Gardens, he (Mr. Hope) recollected when they were regularly cropped with Potatoes and Wheat. A short time before Mr. Thomson came they were laid out in flower beds, but since his magic wand was waved over them they had become famed over the length and breadth of the land. Mr. Thomson was now going to take charge of one of the largest, if not the largest, gardens and grounds in Scotland; and so far as it might be considered a professional step, it was one of the highest in the kingdom. All his friends rejoiced in this, though they could not but regret the loss they would experience in being deprived of that social intercourse with him which they had had the happiness to enjoy, and still more the ready advice which he always cheerfully bestowed in aiding them to obtain increased luxuries from their gardens. He (Mr. Hope) had no doubt that Mr. Thomson would soon gain for himself new friends as attached as those he now left behind him. He carried with him the best wishes of every one, and in the name of the subscribers to the testimonial, he now begged Mr. Thomson's acceptance of it, and to add that it was their earnest wish that he might long be spared to enjoy health, happiness, and prosperity. (Applause).

The testimonial consisted of a very elegant gold watch and chain, a timepiece, and a silver tea service to Mrs. Thomson. The watch, which was of the most massive character, bore the following inscription:—"Presented to Mr. D. Thomson on his leaving Archerfield by a large number of friends, as a token of their admiration of his professional abilities, and esteem for his private virtues, 5th November, 1868."

Mr. Thomson, in acknowledging the gift, said—I feel it to be quite beyond the compass of my power to command words which shall convey to you a proper impression of my feelings on this, to me, memorable occasion. When a person finds himself placed in such a position as mine at the present moment, it is most difficult to avoid putting the question to one's self—Have I in any way merited or deserved such tokens of esteem and regard, and such a recognition as I am now honoured with, and presented with such a valuable and splendid testimonial as you have bestowed upon me? To say to you that I feel quite unworthy of all this is undoubtedly my feeling; but I will not dwell on that topic, seeing that I have been judged otherwise by you and those whom you are here to represent. I am one of those who think it an honourable ambition to act so as to earn the good will and respect of my fellow men, and Solomon says that "A good name is better than riches, and loving favour better than silver and gold." Since I came amongst you, ten and a half years have rolled over

us—to look back it seems but yesterday. These years present many happy and pleasant resting places for my mind to rest upon, and though clouds and gloom—the common lot of us all at times—have passed over my fireside, we can always look back with gratitude and thankfulness to the kindly feeling and many acts of disinterested kindness which we have experienced in Dirleton. The event of this afternoon has brought these many expressions and acts of good will to a climax, and for these all, and especially for this, I beg to thank you with a sincerity of which I am profoundly conscious. Reference has been made to my professional labours and ability. Whatever of these can be laid to my credit has been acquired, to a very considerable extent, by contact with the long-celebrated gardeners of East Lothian, and to them I owe a double debt of gratitude for much substantial aid and good fellowship. I leave this district with great reluctance, and not for the sake of greater emolument, nor for any banking after change. Circumstances have, however, arisen which have made it not consistent with self-respect for me to remain any longer here. In the kind providence of God I have been successful in getting into the service of an employer who stands unrivalled as a nobleman of high honour, good sense, and kindly feeling, and I trust I may be enabled to fill that situation with as much credit to myself and satisfaction to the Duke of Buccleuch as Mr. McIntosh has filled it for the long period of twenty-eight years. Mr. Thomson concluded by again thanking his friends for their great kindness and good feeling towards him, in making such a splendid present.

PLANTS IN BLOOM DURING OCTOBER.

Oct. 5. <i>Oenothera missouriensis</i> <i>Chioscocc racemosa</i> <i>Berberis Darwinii</i> <i>Vinea major</i> <i>Aster paniculatus</i> <i>Chelone barbata coccinea</i> <i>Eryngium planum</i> <i>Parnassia palustris</i> <i>Ajuga reptans variegata</i> <i>Sedum Sieboldii</i>	Oct. 16. <i>Salvia patens</i> fulgens <i>Aster dumosus</i> <i>Eschscholtzia californica</i> <i>Morina persica</i> <i>Rhododendron ponticum</i> " 19. —M. H., Acklam Hall, Middlesborough-on-Tees.

CLARKE'S INSECT-DESTROYING COMPOUND.

In answering questions in reference to my Compound, I wish to remark that I do not recommend Grapes to be syringed after the bloom has begun to form, which it generally commences to do before they begin to colour. They may be syringed up to this time without injury to the fruit, but immediately the Vine has been syringed every bunch should also have a good syringing with clean water in order to wash the solution out of the bunches, or it would lodge between the berries, dry on them white, and spoil their appearance.

I had last year one or two Peach trees much infested with scale, and in the spring of the present year I thought I would try a decoction recommended by one of your correspondents. It consisted of soft soap and bitter aloes, at the rate of 2 ozs. to the gallon, boiled; but I found it discoloured the fruit, and how to remove it I did not know. The scale was also making its appearance again. The fruit was in its second swelling when I discovered my Compound. I gave both trees and fruit

a good syringing, and it not only cleansed the fruit but killed all the scale. Nothing more was required until the fruit was ripe, when the red spider attacked them; but when it was gathered I gave the trees another dressing, and next morning not a red spider could be found.—T. C. CLARKE.

THE MIRABELLE PLUM.

For very many years I have admired this charming little Plum, and have often felt surprised that it is so seldom cultivated in England. It is not to be thought of as a dessert Plum, for uncooked it is rather dry, with a dull sweetness, and of no taking flavour, but when cooked or made into jam its flavour is delicious; and what is very remarkable, although there are hundreds of varieties of Plums, not one has the peculiar aroma of this sort. If bottled (without water), the flavour is fully preserved, and a tart or pudding of Mirabelle Plums at this season is a real treat.

Some years since, when Louis Philippe was king, I happened to visit the *potagerie* at Versailles, and there to my surprise I saw scores of baskets of this sort of Plum gathered ready for the Royal kitchen. On inquiry I found it was the favourite Plum of the Royal Family, no other variety equalling it in flavour for compotes, &c. I afterwards learned that in the east of France it was equally esteemed, as it is now—it is, in fact, called Mirabelle de Metz. Its small oval fruit, bright yellow mottled with red, are most ornamental on the trees, and its stone the smallest of all Plum stones, being smaller than that of the Morello Cherry. The tree is best cultivated as a bush, and when in blossom should have a covering of light flannel when the nights are frosty. It requires a dry warm situation, and is well worthy of extra care.—T. R.

LUMINOUS INSECT.

I USUALLY walk round my garden paths in the evening, and continually have my attention attracted by finding one at my feet—I think a glowworm. First it is the bright body in a round mass; it then appears to separate, and part of it like a thread moves away from what was the main body, leaving an illuminated piece behind, which, with the part in motion, gradually becomes feebler in light until it ceases altogether. The peculiarity is, that it makes a circuit and returns to the first spot, the whole train being slightly illuminated.

Sometimes two are performing the same movement simultaneously.—R. J. S.

The insect above described is not a glowworm, but one of the small species of centipedes, which in the autumnal months, which is the pairing season, become luminous. From the last paragraph it would seem that both sexes have the power of emitting light. The species is scientifically named *Geophilus electricus*.—W.]

NEW BOOKS.

The Miniature Fruit Garden. London: Longmans.

It is with great pleasure that we announce the appearance of the fifteenth edition of Mr. Rivers's "Miniature Fruit Garden," just issued from the press. After passing through so many editions as this useful little work has done, it may appear superfluous to say anything in its praise. There are new generations always arising to whom all things are new, and to whom "The Miniature Fruit Garden" forms no exception. To them we will convey an idea of what the work is, by an extract from page 83. "A French pomologist," says Mr. Rivers, "who visited me in 1861, said, 'Ah! now I find an Englishman planting for himself as well as for his children.' " This is the text of the treatise, to teach a man how he may eat the fruit of trees which his own hand has planted. For the benefit of those who already are acquainted with this work, we may state that they will find in this new edition much useful matter which has not appeared in any of the former.

The Gooseberry-Grower's Register.

This is the new edition of an annual which has appeared, we believe, without intermission for more than a century. It is a most unpretending little volume, and, therefore, is not so much known as some of its more pretentious contemporaries, but it is, nevertheless, to fruit-growers one of the most interesting and useful publications, while to the general public it is an object

of the greatest curiosity. It is a record of all the Gooseberry exhibitions throughout the year 1868, the names of the exhibitors, the berries shown, and their weights. The largest berry shown was London, 29 dwts. 19 grs., at Brough, Derbyshire, by Mr. Phineas Highton, Alderwashley, near Wirksworth. Whoever sends 1s. 8d. to Mr. Leicester, nurseryman, Crompton Road, Macclesfield, will have a copy of the Register returned to him.

VINE ONE YEAR OLD BEARING TWENTY THREE BUNCHES OF GRAPES.

THE truth of the statement, at page 279, being doubted by more than one of our correspondents, we wrote to Mr. Roberts, and the following is his reply:—

"I wrote to Mr. Meredith's, at Garston, forwarding the letter you enclosed for me, also the Journal containing my statement, and I now give Mr. Meredith's foreman's reply. He also sent me a sample of the eyes the Vine is furnished with, which I have shown to several of my gardening friends, who all say they never saw more fruitful-looking eyes and wood, for the eyes look like nuts. This certainly shows that the crop has not taken all the vitality to mature the fruit, but that there is wood able to bring to perfection double the quantity next season if allowed.

"When I entered the house in which Mrs. Pince's Black Muscat is planted, for it is in an inside border, if the question had been asked, How long I thought the Vine had been planted? I certainly should have guessed six or seven years, for it looked quite as vigorous in growth as if it had been planted that length of time, the bunches being in such fine condition, and the wood so strong and firm. I can assure your correspondent who is so fond of Vine culture, that he would never regret paying Mr. Meredith's vineyard a visit; there he would have the pleasure of seeing the powers of Mrs. Pince's Black Muscat tested, and the wood it is furnished with for next year's crop, after bringing to maturity a greater quantity of bunches than he states in his letter.—CHARLES ROBERTS, *Dorfold Hall Gardens, Nantwich, Cheshire.*"

The letter from Mr. Meredith's foreman is as follows:—

"Your statement concerning the Vine of Mrs. Pince's Black Muscat is substantially correct, but you have underrated the weight of fruit. The facts are as follow:—The Vine was planted in the summer of 1867, and was then a small one, certainly not more than 3 feet in length. It bears now twenty-one bunches, two having been taken off, a berry at a time, for tasting. The weight of the twenty-three bunches would be at least 30 lbs., several of them being nearer 2 lbs. than 1 lb. in weight.

"I have measured the stem this morning, the circumference at the base is 6½ inches, and at 2 feet from the bottom it is 5½ inches. I enclose a sample of the eyes it is furnished with, which certainly do not look like barren ones.—WM. TAYLOR, *The Vineyard, Garston, near Liverpool.*"

COST OF HEATING AND MANAGEMENT OF A BOILER—GARDENERS' WAGES.

IN answer to "C. C." and others, for single small houses where only a little heat is wanted to exclude frost, there is no other plan so economical as having a brick or an iron stove, with a small funnel through the roof.

2. A flue will heat such a house more cheaply than a boiler, because in proportion less heat will escape at the top of the chimney.

3. Much heat is always thus lost from a boiler unless the stoker is careful, and do what he will much will go to ameliorate the temperature of the surrounding air. We have passed furnaces heating boilers, with fire and furnace doors open, and a glaring red fire in the furnace, and the flickering of the air at the top of the chimney told at once the quantity of heated air that was thus escaping.

Now, as commonly arranged, the following precautions are necessary, so far as securing economy in fuel is concerned:—Clean out the furnace before lighting, close the furnace door after lighting, and leave the ashpit door open until the fire has fairly taken hold and is burning freely; then shut the ashpit door, and if there is a revolver in it just open it a little to secure more perfect combustion, and by the time the fuel is incandescent place the damper in the chimney, just leaving a little opening to allow the gases to escape. To make sure of this, in experienced hands, in the centre of the damper a hole may be made half an inch in diameter, and then the damper may shut in closely, as that opening will obviate all danger, and the heated air, instead of all rushing up the chimney, will to a great extent be sent back to play over and around the boiler. Opening the ashpit door half an inch or less will admit sufficient air to support a slow combustion. When the boiler and pipes are

heated, a slow-burning fire will keep up the heat for a long time. When only a sudden heat for temporary frosts is wanted, we prefer a brisk fire burning itself out. The ashpit door and the damper must be looked to if a continuous heat is to be maintained economically. The whole matter is simplicity itself; but we know practically how very difficult it is to make otherwise clever active men attend to such matters of detail, such seeming trifles.

We can hardly tell whether "C. C.'s" architect, ironmonger, and friends are right in saying he ought to heat his conservatory, hall, and greenhouse, all on a small scale, for £7 or £8 per annum. This we do know, that there will be much waste if the stoking is not attended to as if a man were determined to do it well as above, and without waste; but this we also know, that the veriest rubbish has been affirmed by architects, ironmongers, and hot-water tradesmen as to the little fuel that heating by hot water needs. Hot water will always be economical as respects fuel, in proportion to the great quantity of work done by one boiler, and therefore one chimney. When we use a boiler for a small place, we think of efficiency, cleanliness, &c., rather than the cost of the fuel. Even then the stoker can do much.

As to the other question asked by "C. C.," such a boiler, and with 1½ acre of kitchen and flower garden, and lawn, could in a certain way be attended to by one man and a boy with occasional assistance; but much will depend on the occasional. We have known small houses, such as we may judge his to be, that would almost require the whole of a man's time. We have known them tidy with a few hours' work each day. We can form less idea of the 1½ acre of park or paddock. Altogether, we should judge that where fine plants and much forcing were required, the labour would not be sufficient. Nor do we think that £1 per week would tempt a good man to remain. It would likely have been a saving if, instead of having half a dozen changes, there had been a few shillings a week more given to a good man. A gentleman never gave more than from £55 to £60 per annum, and generally changed every year, or at the longest every second or third year, and every change cost him a considerable amount of money for alterations. By giving £10 or £20 more, he has told us, he has effected a great saving. He found out that everybody he had before came to his place merely as a fill-gap, and was on the look-out for something else, and consequently felt little or no interest in the work. It was very wrong, no doubt, but it cannot be expected that all the virtue is to come from the wage-getting man.

POMOLOGICAL GLEANINGS.

"PERMIT me to add a few words to the excellent description of the MYROBALAN, or CHERRY PLUM, given by "ARCHAMBAUD," page 296. In my youth a gigantic tree of this kind grew in the "front court" of our house, and every season was a mass of snowy flowers, and now and then, perhaps twice in seven years, would give a sprinkling of its pretty fruit, but never an abundant crop, such as I have seen in Touraine, where every branch is often a rope of fruit more numerous by far than the leaves, and most beautiful to behold. I have heard that in some sheltered places in England, perhaps near the sea, it occasionally bears in like abundance. Here, owing to its putting forth its flowers in March, before our spring winter is over, it is rarely that any escape the severe frosts of that or the following month.

"This Plum is evidently as distinct a species as the Sloe (*Prunus spinosa*), for although many thousands are annually raised here from seed to be used as stocks for a few sorts of Plums, which succeed well when grafted on it, no variation in habit is ever seen—they are as constant as Quick raised from haws. There are, however, two or three kinds that vary in the colour of their fruit, one bearing yellow and another greenish yellow Plums, but their leaves and shoots seem never to vary. The latter kind is common in Belgium, and is used in their sandy soils for stocks for Plums, Peaches, and Apricots. This kind strikes freely from cuttings in the light peaty soils of Belgium, where it is called the Mirabelle Plum. One peculiar characteristic of this stock is its immunity from the attacks of the Plum or any other kind of aphid, often so injurious to all other kinds of Plums. Seedling Cherry Plums form finer trees than those that are grafted, as they have naturally a graceful pyramidal habit, and would, if planted in shrubberies, require no care, soon becoming trees, always ornamental and sometimes fruitful.

"Some years since a kind of Plum was introduced to the Hor-

ticultural Society's gardens at Chiswick, which (trusting to memory), Mr. Gordon, who then had the care of the new introductions, told me was sent from the Himalayas as the original species from which the Green Gage Plum had been raised—in other words the wild Green Gage Plum. I looked at its vigorous glossy shoots with great interest, and obtained some buds, being then as now a Fellow. In a year or two my young trees were placed in pots, and I gloated over the idea of seeing our favourite Plum of the shape and size of a Sloe, only green instead of purple, and thus being able to trace it to its origin. Alas! my trees, placed in one of my orchard houses, bore abundantly, and gave a death blow to my hopes, for they produced a fine crop of true Cherry Plums.—T. R.

—ANOTHER proof of the influence of last summer in ripening fruit has been sent to us by J. B. Danbury, Esq., Buckingham Villa, Ryde. It is a well-ripened though rather small POMEGRANATE, borne by a standard tree in the open garden, and which never bore fruit in any previous year.

BENTLEY PRIORY.

(Continued from page 187.)

BEFORE entering the conservatory Mr. Rutland called my attention to a fine quarter of Strawberries in front of the long range of vineries. They had preserved their fine foliage and vigour all through the trying season, and the quantity of fruit they had produced was extraordinary; I am afraid to say how many bushels were gathered from a plantation about 30 yards square. This was owing to the mode of preparing the soil adopted by Mr. Rutland before making his plantations. It is one which I have before described, and will amply repay the cultivator for the extra trouble taken at the commencement. For the benefit of those who may contemplate making new plantations, and who may not be acquainted with this system, I will here give a brief outline of it as pursued by Mr. Rutland with so much success.

In the first place, the ground should be trenched to a depth of 2 feet 6 inches, or more if the subsoil is good. Secondly, plenty of manure should be placed in the bottom of every trench (when I say plenty, it means from 3 to 5 inches); then after the whole of the piece intended for the new Strawberry plantation has been trenched over, another slight coating of well-decomposed manure should be spread all over the surface of the ground and pointed-in with the spade, leaving the surface as rough as possible, so as to expose it fully to the action of the air and frost. The present is an excellent time to prepare the ground as above described, and it may so remain till March, when a favourable opportunity should be selected for planting out the Strawberry plants in the new ground. If an early lot of runners was taken off in the previous summer and pricked out about 6 inches apart in a piece of rich ground, by this time they will have grown into fine healthy plants, and care should be exercised in their removal to injure the roots as little as possible. If a small trench is taken out at the commencement of the nursery bed the plants can be removed row after row, with balls of earth attached to them, without the slightest injury to their roots. They should then be planted with the same care in rows about 3½ feet apart, and 2½ feet from plant to plant in the rows. After planting, the soil may be just pointed over with a fork between the plants, shaking a little manure about them as each row is finished, to shelter them from the March winds and spring frosts.

In such a season as we have experienced, the benefit to be derived from placing the manure at the bottom of the trenches will at once be seen; the roots go down in search of moisture, they are also attracted by the manure, and the plants will then be able to withstand uninjured any amount of dry hot weather such as we have had this year, and in this way they produce immense quantities of first-rate fruit. The manure pointed into the surface of the soil is for the purpose of encouraging root action as soon as the plants are planted out, and to enrich the soil brought up from the bottom of the trenches, which is generally very poor unless the same piece of land has been subjected to a similar course of treatment in previous years.

The conservatory, one of the most magnificent buildings of its kind in the country, is situated on the west side of the mansion, and is approached by three entrances; one communicating with a splendid suite of rooms in the mansion, another with the terrace gardens, and the third with the corridor mentioned at page 187. From the last-named approach I entered this noble structure, which gives one an idea of the great wealth

and taste which the owner of this fine estate possesses. The building is 130 feet long, 23 feet wide, and 36 feet high in the centre. There is a path through the centre paved with Minton's tiles, and on each side at intervals fine pedestals, on which are placed some of the costly Majolica vases, which were purchased at the Great Exhibition of 1862. They are exceedingly handsome, and appear to preserve all their colours perfectly. They are filled with flowering plants, Ferns, and two or three of them with large plants of the graceful *Adiantum cuneatum*, about 3 feet in diameter.

Behind the vases are arranged numerous flowering and ornamental-foliaged plants, amongst which I noticed fine specimens of the following—*Musa ensata*, *Oleanders*, *Oranges*, *Camellias* splendidly set with flower-buds; noble plants of *Dicksonia antarctica* and *D. fibrosa*, *Cyathus medullaris*, having a clean stem, and fronds in perfect health from 12 to 14 feet long, a splendid *Seaforthia elegans*, and *Chamaecrops excelsa*, with several handsome trees of *Araucaria excelsa*.

In the centre of the conservatory is a beautiful fountain, and at the back of this a magnificent half-circular seat, the background of which must have cost a very large sum, the painting being very rich and good. Opposite to this there is a grand entrance to the terrace gardens, and on each side of the door is the finest pair of *Dicksonia antarctica* I have ever seen. The plants are dwarf, but have fronds of great length and beauty, which have a very pleasing effect. These noble plants now require more than double the space at present allowed to them.

Whilst standing at the door of the conservatory, one of the most charming views I ever beheld was presented to my gaze. In the distance is seen a beautiful undulating country thickly clothed with trees, and directly opposite me was the classic hill of Harrow, with the beautiful spire peeping up above the dense masses of trees. As soon as the mind has comprehended these beautiful distant views, and there is time to look around, one of the grandest scenes of floral beauty which it is possible to imagine commands our admiration and invites inspection. Here, upon a position eminently calculated to produce an effect, much care and thought have been brought to bear. Accordingly the ground has been made the most of, and the arrangement of the terraces are thoroughly in keeping with the mansion, and other surrounding objects.

A noble flight of stone steps leads down to the first level of the lower garden. In front of the conservatory there is a mixed border, which had a very pleasing effect; this border is continued eastward for some distance in front of the mansion, and terminates where a fine flight of steps leads up to a balcony at a considerable elevation above the terrace gardens, and from which a view can be obtained of the whole of the beds, as well as of a large tract of beautiful woodland beyond. The walls of the mansion are covered with large scarlet and other *Pelargoniums* and with suitable climbers; and in front of the balcony wall a narrow border, on the same level as the first terrace walk, was filled with a miscellaneous collection of flowering plants. Beyond the balcony, and at the eastern extremity of the mansion, there is a recess, which seems to me a most suitable place for a handsome orangery or tropical conservatory, which would be a very important addition, and would give the mansion and the terrace in front a more uniform appearance. On this piece, which is only grass at present, there are three large circular beds (see a in the accompanying plan), which are filled with Roses and scarlet *Pelargoniums*, and trained in the form of pyramids. The bed filled with the scarlet *Pelargoniums* was the best I have ever seen, being at the time of my visit one complete mass of scarlet from top to bottom. These beds were about 12 feet high in the centre, and as many feet in diameter at the base. The effect produced by such masses of scarlet flowers at a distance was magnificent, backed up as they were by large masses of evergreens.

Retracing one's steps along the first gravel walk, which is 17 feet 6 inches wide, to the west end of the balcony, on the side of the walk nearest the mansion there is a very pretty group of beds. These have a neat chain of beds round them, and were planted as follows:—The eight-sided bed with Mrs. Pollock *Pelargonium*; the two long angle beds with *Pelargonium Lady Middleton*, splendid masses of colour; the two triangular beds, yellow *Calceolarias*; the narrow border, Purple King *Verbena*; the chain beds surrounding the group, Gold and Silver-edged *Pelargoniums* alternately; outer border, *Verbena Tweediana*. This was a very pleasing and tastefully-arranged group.

Continuing to pass along the walk towards the west, we come to two more groups of beds in front of the conservatory, the

steps leading up to the conservatory dividing the groups from each other. The beds in both were planted alike. The centre is a group of lobed beds, with two circular beds on each side, and a triangular bed between each pair of circular beds. The central group was filled with a mixture of flowering plants; the narrow-lobed border, surrounding the group, with Golden Chain Pelargonium. In the two triangular beds the centre was formed by a fine standard plant of Madame Vacher white Pelargonium, and the ground beneath it covered with a scarlet Verbena. In each of the circular beds are handsome standard Laurustinuses.

Here the straight portion of the walk terminates, and curves gradually towards the south-west, leading to the pleasure grounds and park, and from thence to the kitchen gardens, which are about half a mile distant. On the south side of this walk there is a handsome panel garden, 350 feet long and 42 feet wide, surrounded by grass. It is about 4 feet below the walk, and a handsome flight of stone steps at each end of the terrace communicates with the garden. There is a sloping bank of grass between the first walk, which is parallel with the mansion, and the panel garden. This portion I shall designate *v*. The west end consists of a group of twelve beds. The centre of the group is an oblong bed, the central portion of which was planted with Pelargonium Clipper; then there was a double row of Christine, and at the outside, next the grass, an edging of yellow Calceolarias. There are four corner beds, which were planted to pair crossways, the centre of two of them being filled with Pelargonium Flower of the Day; then there was a band of Lobelia speciosa, with an edging next the grass of Cerastium tomentosum. The other two were planted in a similar manner to those just mentioned, the only difference being the substitution of Pelargonium Bijon for Flower of the Day. There are four circular beds in the intervals between the angle beds. Those on the north and south sides had a standard Pelargonium for the centre, with a groundwork of Colens Verschaffelti and Centaurea candidissima; the other two, facing east and west, had for their centres standard Calceolarias, with a carpeting of Iresine Herbstii and Centaurea candidissima. This was the first time I had ever seen standard Calceolarias used in any bedding arrangement. They were exceedingly fine plants, each with a clean stem about 3 feet high, and above this a fine head trained to a wire frame, and completely covered with bloom. The variety used is Amplexicaulis, and this mode of training is certainly novel and effective, giving at intervals a pale primrose tint, which is very pleasing, and producing along with the bright colours beneath a beautiful combination, without that vulgar appearance too often met with where the common yellow Calceolaria is extensively used with scarlet and other brilliant tints.

On the east side of this group there are three round beds; the centre one was filled with Heliotropes trained in the form of pyramids about 8 feet high, and completely covered with flowers, which diffused a sweet perfume, and helped to tone down the bright dazzling colours of the two large pyramids of scarlet Pelargoniums on each side of it.

At this point a walk 12 feet 6 inches wide crosses the terrace from north to south, the north end facing the entrance to the conservatory; and at the east end of the terrace there is another cross walk, of precisely the same width as that at the west end of the terrace, and beyond it another group of beds planted just the same as that last described. Between these two cross walks, and directly opposite the principal portion of the mansion is the finest and most elaborate display in this division. There are three groups of beds, forming a very pleasing and tasteful arrangement even in winter, for the beds composing it are interspersed with evergreen shrubs, which relieve the bright floral display in the summer, and prevent the beds assuming a barren appearance in winter. They may, however, be filled with spring-flowering plants or evergreens, but I forgot to ask Mr. Rutland whether such was the plan adopted or not. In the centre of the middle group, if my memory serves me rightly, is a vase considerably elevated above the level of the ground, and it was filled with Tom Thumb Pelargonium. Round it there are eight beds, with semicircular ends, also planted with Tom Thumb, and between these eight handsome plants of Thunja aurea. On the east and west sides of these beds there are oblong beds, with the sides facing the central group slightly incurved. The centres of these were filled with a Petunia called Smith's Superb, a beautiful crimson-shaded purple, something like the old Countess of Ellesmere. It is one of the finest and most useful in colour I have ever seen, and was conspicuous among all the other colours which were employed in the arrangement, bright and beautiful though many of them

were. Surrounding this Petunia, in each bed was a broad band of Mangles's Silver Variegated Pelargonium; its neat silvery foliage and pink flowers looked very pretty in conjunction with the beautiful crimson purple of the Petunia.

Directly behind the oblong beds just referred to was a pair of very handsome pyramidal Box trees. Partly embracing these, is a sort of winged scroll on each side of the Petunia beds. The ends of the scroll were filled with Pelargonium Golden Chain, which is still one of the most useful of our bedding Pelargoniums. Right and left of these scroll beds are round beds, having on each side a somewhat triangular bed slightly incurved on three sides. The round beds had in the centre of each a standard scarlet Pelargonium, with a groundwork of white Verbenas; and the other four beds were planted as follows:—Centre, Beaton's Silver Nosegay, one of the finest of all the Silver-leaved Pelargoniums, bearing above its foliage a dense mass of violet-shaded rose-coloured flowers, which looked extremely beautiful; next came a broad band of Lobelia speciosa, then an edging next the grass of Cerastium tomentosum. These four beds, and the two beds with their centres filled with the Petunia mentioned above, I considered the finest of the whole series. Those who do not possess these old but valuable plants should lose no time in procuring them, in order to propagate them for a splendid display next year.

The next beds are round, having for their centres standard Calceolarias, and the ground carpeted with Purple King Verbena. Surrounding each of these is a series of beds, eight in number, having straight ends. In the centre of each of these was a standard Calceolaria, the ground covered alternately with Verbena Purple King and Tweediana. These had a very pretty effect. Next to the beds last referred to is a pair of circular beds filled with Calceolaria Amplexicaulis pyramid-trained. The plants were about 6 feet high, and a perfect mass of bloom. A pair of crescent-shaped beds, incurving towards the pyramids, comes next; the centre being filled with Pelargonium Stella, with a broad band of Mangles's Silver Variegated next the grass.

This concludes the principal division, *v*, and in reading this account, it must be understood, that after describing the two end groups, I commenced in the centre of the main group, extending right and left from the central group of beds to the walks which cross the terrace, dividing the group of beds on each side from the main or central one.

At the south end of the cross walks a flight of steps brings us down to another level, and here another broad gravel walk traverses the whole length of the division of the garden described above. This noble walk is 20 feet wide, and 350 feet long. On its south side there is another fine green sloping grass bank, and between the bank and the gravel walk a level margin of grass about 4 feet wide. On this there are planted at intervals of about 18 feet, the finest standard Portugal Laurels I have ever seen. To a casual observer, it would appear that the whole of these fine trees were in tubs, standing on square blocks of stone, and I was on the point of asking Mr. Rutland how he managed to keep such large trees luxuriant in tubs so small, and containing such a small quantity of soil. I began to fancy he had been giving them Standen's Gardener's Friend, as it had served him so well with Azaleas and Camellias, but Mr. Rutland said, pointing to the splendid row of trees, "This is one of many of Mr. Kelk's excellent ideas." These trees are planted in the ground, two pieces of stone have been made to fit closely together, a place for the stem of the tree being cut out of the centre of the stones, then an ordinary-looking square Orange tub, about 2 feet 6 inches square, and about the same in depth, has been fitted round the stem of each of the trees. The stone on which the sides rest forms the bottom. Into these square tubs soil has been filled round the stems to within an inch or two of the top, then on the soil a covering of neat white-looking stones is placed. This finishes Mr. Kelk's system of potting his Portugal Laurels, and every one who has seen this splendid row of trees, will say that Mr. Kelk devised an excellent plan of deceiving the eye, and providing for the well-being of the plants. They are in fine health, with beautiful straight stems, and finely-formed heads of bright glossy green foliage, which give a very fine effect to the terrace.

On the other side of the walk, and between the terrace wall, which is very substantially built, there is another margin of grass, about 10 feet wide, on which there is a chain of flower beds (c in plan), which runs parallel with the walk for about 125 feet. At each end of the terrace these sections are cut in two by the walks which cross the three levels from north to south, both leading by a fine flight of steps through the terrace wall

to the arboretum and pleasure grounds below the terrace. So there are five flights of steps to be seen, one above the other, rising from the various levels at the west end of the terraces, the uppermost leading to the conservatory. At the east end four flights of steps are seen, the uppermost leading to the balcony previously described. In the centre of the interval between the cross walks, and directly opposite the grand portion of the terrace, a fine semicircle is described beyond the parallel line of the terrace wall, and the chain of beds referred to above is continued round that section of the terrace wall. This chain was planted as follows, and had a very charming effect. There were round beds which formed the centre of the chain, or round dots in it, filled with *Christine Pelargonium*, surrounded by a band of yellow *Calceolaria*. Between these there are oblong beds, the centres of which were filled with *Pelargonium Stella*, with a mixed band of *Lobelia speciosa* and Golden Chain *Pelargonium* outside, next the grass. The arrangement was just the same on each side of the semicircle, but that of the chain inside the latter was varied, by the oblong portions of the chain having for their centres *Pelargonium Stella* next a double row of *Verbena Purple King*, with an edging next the grass of yellow *Calceolaria*.

In the centre of the half circle is a very fine basin built with clear white marble, and east and west of it two angular beds, which were filled with *Pelargonium Lady Middleton*. These were the finest masses of bloom I have ever seen. In front of these, and forming a crescent on the south front of the basin is another chain of beds, and between this and the chain which follows the course of the terrace wall there is a walk 7 feet wide. The chain, which is the last portion to be described of this grand floral display, was planted as follows:—The round portions had centres of *Pelargonium Crystal Palace Gem*, with a broad edging of *Alyssum variegatum*; the oblong beds had for their centres *Pelargonium Mountain of Light*, with the white portion of its foliage as white as the driven snow. This is certainly one of the finest of the white-edged bedding *Pelargoniums* we have in cultivation; indeed, I will go farther and say, it is the best of them all. Round this was a double row of blue *Lobelias*, with an edging of *Alyssum variegatum*.

The south front of the terrace wall is partly covered with roses, and in front of it there is a border filled with *Mignonette* and other sweet-scented plants, which shed a grateful perfume, which is borne on the breeze to distant parts of the beautiful terraces, conveying pleasure to the sense of smell, whilst the eye is enjoying the beauties which surround one at every step. But knowing, however, that there was still much more to be seen, I very reluctantly turned away from the enchanting scene, and on my way to the kitchen gardens, the thought occurred to me, How does Mr. Rutland propagate such quantities of bedding

plants? In walking through the houses, I saw no building specially adapted for such a purpose, nor any place very suitable for their growth, after they had been propagated. The fruit houses must, therefore, be crammed with plants throughout the early spring months, thus requiring a vast amount of care and attention on the part of the gardener to keep his Vines and other fruit trees free from the many insects which breed on the plants used for bedding purposes, and which, if allowed to establish themselves on the fruit trees, very often spoil the crop. The bedding plants most certainly take from the atmosphere a very large amount of food, and thus rob the fruits of what is most essential for their proper development. I therefore thought it was a pity that an establishment so replete with almost every other convenience, should not have a proper propagating house, and a few ranges of heated pits for the propagation and growth of what constitutes the great feature of this establishment during the summer. But it is the same in almost every place; this provision is generally forgotten, or the proprietor of the establishment cannot be persuaded that such places are necessary. It is to be hoped that their necessity will be recognised in the formation of establishments where large numbers of bedding plants have to be produced, and now that small glass structures, which are the most suitable for the purpose, can be erected so cheaply, few ought to be without them.—J. WILLS, F.R.H.S.

NOTES AND GLEANINGS.

ACORNS have been introduced into the London corn market at Mark Lane, and have been sold within the past fortnight at £4 per ton in the warehouse; a ton is about 5 quarters = 40 bushels, at the estimated weight of 56 lbs. per bushel. In another case they were sold at 12s. per quarter, to be delivered at the Great Western Railway terminus in London. Some kiln-dried acorns have been offered at £7 per ton, but that is not considered a paying price, as the waste in drying is so great. It is of interest to remember that the price of Potatoes is not double that of acorns, and that these, when cooked, are good for all kinds of poultry, as well as for pigs. As for the absurd stories which have been told about their causing disease in pigs, they are refuted by the universal experience of mankind. Polybius, speaking of the plains of Lombardy, 200 years B.C., says, "Their forests, which are spread over the country, afford so large a number of acorns, that, though great numbers of swine are consumed by the inhabitants of Italy, as well in the use of private families as in their armies, yet are they chiefly furnished with them from these plains."—(*Medical Times*.)

A MOST useful work on the EATABLE and POISONOUS FUNGI of Sweden has lately been completed, containing a very valuable series of drawings, for the most part illustrating those of which it is most desirable to have good and trustworthy figures. The text, indeed, is in Swedish, but the drawings are so good that we can conscientiously recommend the work, which is entitled, "*Sveriges ättliche och giftiga Svampar*," as a really valuable acquisition. Professor Fries has now commenced another work, of which the first number has just appeared. It is entitled, "*Icones Selectæ Hymenomycetum nondum delineatorum. Folio, tab. pictæ X.*" We trust that this very excellent work will meet with support in this country as well as in Sweden, and the more especially as its progress will depend very much on the patronage which it can command.

THE pig was formerly employed in all parts of France in hunting for the TRUFFLE, which has just appeared in the Paris markets, and in an abundance which has not been equalled for the last sixty years. There is a celebrated caricature of Gavarni's, in which two women of the people are represented as discussing the vintage. "They say there will be plenty of wine this year," says the first lady; and the other replies, "How we shall get trounced!" Looking at the plentiful supply of Truffles, *gourmet* and *gourmand* will probably exclaim, "How we shall suffer from indigestion!" In Provence, the ancient country of the troubadour and ballad, the pig is still employed in searching for the Truffle. It is a lean sort of animal, very clever in its way, and is called a *pore de course*, or racing pig, who is duly trained to his business, and for every tuber he discovers he is rewarded with an acorn. In the department of the Haute-Marne the pig has been replaced by the dog; the ordinary cur of the country is trained for the pursuit, and readily masters his craft; his training is neither long nor costly, and his education consists in being kept for a certain time without food, and then set to dis-

cover a Truffle placed with a piece of bacon in a *sabot* filled with earth. As soon as the dog has found the Truffle he is rewarded with a small bit of bread, and the manœuvre recommences. After a few days of this exercise the dog is generally found to be sufficiently trained, and his value reaches as high as £1 at times. There are peasants who make this system of education their trade. A curious fact has lately come to light, which proves that the dog and the pig have not the entire monopoly of finding Truffles. The Truffle poachers trust to a certain fly to guide them to the beloved tuber. A paper on the subject of this fly has been addressed to the Botanical Society of France by M. Gubler, who reports that the insect is large, that he ever returns to the same spot, and, after numerous circuits, settles, and where he settles a Truffle is sure to be found.—*Land and Water*.

— On the 2nd inst., aged 85, died Mr. JOHN WATERER, nurseryman, Bagshot. He supplied the annual exhibition of Rhododendrons at the Royal Botanic Society's, in the Regent's Park.

WORK FOR THE WEEK.

KITCHEN GARDEN.

Cauliflowers.—This has been a fine autumn for late Broccoli and Cauliflowers, but it is not safe to let the latter remain much longer in the open air, as if a sudden hard frost come it will put an end to them. *Endive*, a few plants may be potted at intervals through the winter, and especially early in spring, and placed in a cellar to blanch; they will do exceedingly well treated in this way. *Peas* and *Beans*, from this time to the beginning of next month some may be sown on a warm border if there is little convenience for forcing early crops in the spring. *Store-house*, Carrots, Onions, Parsnips, and Potatoes, will require looking over occasionally, also Dahlia roots before they are finally put by for the winter. All these roots have been housed in a rather green state this autumn, and may, therefore, require more attention in keeping.

FRUIT GARDEN.

Let the hammer be kept constantly at work at nailing every fine day, beginning with Pear trees and following with Plum and Cherry trees. Apples and Pears for spring use may now, or at any time soon, when you are driven in-doors by bad weather, be packed in hampers, boxes, or jars among thoroughly dried fern or kiln-dried straw, and if they are in a good sound state they will then keep better than on the shelves of the generality of fruit-rooms. All trees or bushes that are to be planted or removed on this side of February, should now be finished out of hand without delay, as, after the beginning of next month, we shall be in danger of rough or frosty weather unfavourable for planting. Have the quarters dug and trenched before frost renders the ground too hard, if it is at all in a fit state, and the more heavy work of making new borders, walks, &c., may be left for the dead of winter. Few things are more annoying than canker to those who delight to see their trees healthy and producing good-flavoured fruit. As this is the season of planting or preparing for it, considerable attention should be given to procuring hardy as well as good sorts in all cases where the situation is not the most favourable. In addition to examining the lists of kinds suited to different localities, so often given in answers to correspondents, the planter should take the trouble of ascertaining what varieties thrive best under circumstances similar to his own. One of the chief causes of canker is planting too deeply, the result of which is, that the roots are supplied with more nourishment, such as it is, than the heat and sunshine of the place can duly elaborate, so as to give ripeness and firmness of texture to the young wood. Other causes are the roots striking into an unfavourable soil and furnishing the trees with vitiated juices, the climate of the situation being too cold, or the season too damp and sunless to permit the healthy action of the plant. Where canker exists the diseased parts should be cut out in spring or summer, and the wound covered over with clay and cow dung; but all applications of this nature will be of very temporary influence unless attention be paid to the following things:—Plant varieties the wood of which may be expected to ripen in the situation, improve the climate by thoroughly draining the soil, raise the trees on hillocks above the surrounding surface, after laying a substratum of concrete, tiles, slates, &c., at the requisite depth to prevent the downward progress of the roots, never bury the collar of the tree, expose the soil well to the air before planting, and use no manure except as mulching. You will then generally be rewarded, not by astonishing quickness of growth, nor by your Apple and Pear trees having tower-

ing heads like forest trees, but by seeing them produce healthy though stunted wood covered with fruitful buds, and if you imagine that you must wait a long time for your ground being fully occupied by such moderate growth, you may increase the number of trees.

FLOWER GARDEN.

The subject of the winter decoration of the flower garden was so fully discussed in the last calendar, that it is not necessary to do more at this time than refer the reader to it. An arrangement of this kind gives a garden a highly interesting appearance through the dull months of winter, and the only objection that can be urged against it is, that when bulbs are cultivated they cannot be managed so conveniently as if the beds were unoccupied. This, however, might be obviated by growing both the shrubs and bulbs in pots, but it is very questionable whether the latter could be so well grown as if planted in the open soil. Keep the ground as neat and clean as possible, and roll the walks and grass as frequently as the weather will admit of your doing so. Auriculas will still require well looking after, all dead or yellow leaves must be gently slipped off, taking care not to wound the stem, the top soil must be frequently moved, and if there should be any appearance of bad drainage the soil must be carefully turned out, keeping the ball entire, and more broken pots added. During rainy weather the lights of the frames must be kept on, but tilted behind, and a free circulation of air amongst the pots must be insured by raising the frames a few inches from the ground. Should autumnal blooms be thrown up, pull off the pups as soon as formed; when they happen to be heart blooms it is better to let the stem remain. Carnations in frames will require all the air and exposure possible, avoiding continuous wet. Should any plants appear mildewed, or the leaves become spotted, the diseased parts should be immediately removed, and the plants be placed away from the general stock in a frame to themselves. Pansies that have made long and straggling shoots may now be cut closely leaving a joint above the ground, and hoops should be placed over the most choice beds that protection may be given in the event of sudden frost, which, at this season, is apt to occur after excessive rain.

GREENHOUSE AND CONSERVATORY.

Pelargoniums and Cinerarias require the warmest end of the greenhouse unless there is a compartment for them among the frames and pits. Except these, almost all the greenhouse plants require constant air, and the house to be kept in a sweet and rather dry state. When collections of fine new *Chrysanthemums* have been brought into the conservatory this season, now is the time for making memoranda of their habits, earliness and lateness, &c. There are a few inferior varieties among them yet, but they are all beautiful and fill up a blank between autumn and forced flowers. See that *Luculia gratissima* does not receive too much water; it is very delicate in that respect and must have comparative rest as soon as the flowers are gone.

STOVE.

The *Combretum purpureum* was never known to flower so long as it has done this season, it has been scarcely a day out of flower since last April, and will go on to Christmas to all appearance. Everyone admires the beautiful markings of the *Gesnera zebrina*, one of the most easily-managed of our winter flowers; and *Gesnera longiflora* is by no means to be despised at this late season. Then there is the old *Eranthemum pulchellum*, the best of all the blue-flowering winter plants; while *Justicia pulcherrima* is a blaze of purple. *Aphelandra cristata* and *Justicia pulcherrima* are two distinct winter flowers, although under one name in some books. There is much more danger in overheating stoves than in their being now too cool.

FORCING PIT.

This being crammed with all sorts of plants for flowering in the conservatory and drawing-room, it is now the most critical part of our garden establishment. Forced flowers are coming more and more into use every year, and in these a new branch of trade is fast rising in London, which will soon spread into the provinces. The steady bottom heat from tanks will effect a great change in forced flowers, as many who could not formerly venture on this now difficult branch of culture, will be able to do so with certainty.—W. KEANE.

DOINGS OF THE LAST WEEK.

MAKESHIFTS.

Beetroot.—The frosts in the end of the week made us take up our Beetroot, middling for size, but beautiful in colour,

fearing the frost might be too much, and still more dreading the rats, which had commenced on it in earnest. Much of it which was bitten will come in useful if wanted, as the wounds are well healed over, and quite hard on the outside. Good Beet, and fine Celery, enable one to pass through the winter more comfortably.

Parsley.—Gave a good watering to the row in the orchard house, to which we will go only in severe weather, when the outside beds are hard frozen, or covered with snow. We pity the gardener who cannot gather a handful of Parsley several times a-day in winter. Some good cooks, to their credit, are careful, and make it do several times for garnishing.

Cauliflowers, Endive, &c.—As we could not manage to place these under cover from the sharp frost, we did the next best thing, threw some rough litter over it where it was, treating beds of Radishes in the same way.

Celery.—As we did not earth-up high we covered the remaining part with long dry litter, stuffing it between the plants pretty well up to their tops, but leaving all the tops exposed. We will only cover the tops in very severe weather, but the litter will keep all the upper part of the stems secure, and even the ground free from much frost.

Securing Litter.—Litter is chiefly the dry cleanings from the stable from which all the droppings, &c., have been shaken. It is all very well to speak about straw for covering, but we fear less and less of it will come in the way of the gardener. Dry dung is a good substitute, and it is well to make the most of it. In all places of any considerable extent, it is best for all parties that the gardener should have a certain quantity of this litter, and regularly, and not a load now and then, which in all likelihood he will not be able to obtain when he wants it. Such a system also teaches forethought, and the habit of looking beyond the present. In many places the gardener is allowed all the dung, or part of it, that comes from the home stable, where carriage and riding horses are kept, and this suits very well, as the droppings and short litter come in as the very best for Mushrooms. Of such litter we would never have enough in winter, for protecting frames and pits, Celery, borders, &c., but we have generally more than enough in summer, and this we shake carefully out during a fine day, and then build it in a stack, and to it we go in any emergency, and can thus have litter for use without troubling anybody. Within the last week we have made fair inroads on our store, but still we have a good heap left, which we trust will not be all gone until the bedding plants are safe for the outside beds in spring.

Took up a quantity of *Sea-kale* and *Rhubarb*, placed the roots in the Mushroom house, and will give them a little more heat in a week or so. Neither is any better of too much heat at first. Packed with litter, and a little earth thrown over it to keep it down, stools of *Globe Artichokes*, *Sea-kale*, *Rhubarb*, and even *Horseradish*, so that the frost shall not penetrate much into the ground. A very little loose litter prevents injury from frost. For protecting the roots of plants at all tender, nothing is better than an inch or two of moss. Even north of Edinburgh, huge bushes of *Fuchsias* used to bloom freely in the open air, the shoots cut down to the ground every autumn, and the stools covered with moss, which was nearly decayed as the young shoots came in the spring, and in severe springs these sometimes were helped for a few weeks with a hand-light. Thus treated the huge bushes were magnificent, far before those even in the south, where the stems stood the winter.

FRUIT GARDEN.

Strawberries in pots began to give us some concern, owing to the heavy rains and the frosts of the 6th and 7th inst. We had some litter laid on them where they stood, but that was in a conspicuous place, and did look untidy, and after a fine day there was always the chance of the pots, when exposed, being caught with a severe frost. We thought of several plans for making them safe, and at last, on the 7th, adopted the following:—As already stated, we had put some litter on the Vine borders; and that of the latest house, in addition, had been covered with some old sashes, which were condemned twenty years ago, but without the help of a bearer or rafter, or much done to them, they have done good service in turf and earth pits, &c., ever since, though old and shaky enough. Well, on the border we made a bed for Strawberries, forking the litter over, adding a little more, and making a wall of litter from our stored-up heap back and front, on these laid longitudinally the boles of some young trees, on which to lay the ends of the sashes, top and bottom. The pots were plunged in the bed, as the heat given will scarcely be appreciable, and,

the sashes placed over them, they will need nothing whilst they remain there, except a little litter thrown over the sashes, if the weather as respects frost should turn out very severe. We would have preferred an earth pit for this purpose, but we had none at liberty, and though part of the border may ere long need a little more covering, the pots will mostly be elsewhere before then. Our plants were protected last year for the most of the winter where they stood; but this involves much trouble, and a mistake in leaving the pots exposed to sudden and severe frost does them much injury.

We have been able to do nothing as yet with our *orchard-house trees in pots*, and fear we cannot begin potting afresh, which we think they must need; but if not, we will remove some 2 inches of the top soil and fresh surface with rich compost. We should have liked to have done the repotting, if we had used the same sized pots again, before the leaves had all lost their green tint, so that the green leaves would have helped, by reciprocal action, to send the fresh roots into the new soil. Some of these trees have been from five to six years in the same pots, and produced heavily every year—in fact, there is no saying how long they might remain in the same pots if they were rough root-pruned every year and fresh-surfaced in autumn as above, and fresh-mulched every month at least during the summer. Our pots are fully one-half plunged in the border to save watering, and in most cases the roots will pass out a little in summer, and the rough root-pruning to which we shall presently subject them will be the lifting the pot up, consequently breaking the roots beyond. When we replace the pots we put a little fresh rich loam in the bottom of the hole. To make the most of the room, we sometimes take all the pots up, place them on the surface as closely together as possible, and pack a little litter among and over the pots for the winter, and then we have the space thus secured for Strawberries, Lettuces, Endive, Cauliflowers, &c. This plan, however, involves considerable labour, and a little risk of injuring the trees in moving them about.

A few weeks ago we dwelt on the importance of *planting fruit and other trees early*, and the mode of doing so, especially with the view of meeting the circumstances of the possessors of small gardens, and as we can add little or nothing, we would refer intending planters to what has been previously said. From the accounts that reach us, all planting of trees that took place since last March has been attended with unfortunate results where no extra attention could be given to them, but they had to take the chance of the season as it came. With the number of nurserymen all over the country, it is advisable not to have trees from very long distances, unless the roots are packed so as not to be dried in the journey. In fact, it would be true economy to have the trees not drawn up, but taken up and carefully packed in damp litter, and to pay a little more for the additional trouble. We had men digging holes for a plantation of trees and cover yesterday, and despite of the frost on the surface, and the cool air, the soil was delightfully warm, and neither too wet nor too dry. It requires no reasoning to prove that if we put the trees into these places now they have more chances to do well than if planted after the New Year, and onwards. In order to perform such work now, it is worth while making sacrifices, and we must make them, by allowing some matters to be in abeyance that ought to be attended to. In digging or making holes now, wherever water is found, it is a sure sign that drainage must be attended to before even the commonest trees will thrive.

Glazing.—As winter approaches, care must be taken to have sashes, even if old, in pretty good order, and free from drip, and this can only be secured when the old plan of glazing is followed by having the putty sound. Even though late, we have cleared off the loose putty from many sashes, in dry days run a paint brush along the sides, using rather thick paint with driers and turps, so as to dry quickly, and then the putty nicely put on will adhere well, and will not move, especially if in a sunny day we draw a small brush of paint over it when dry. It is all very well when mending a square in a hurry, not to trouble with the paint brush, but in all lengths of glazing of any extent, it is true economy to run the paint brush with a thin coating of paint over the wood, and allow the paint to become dry before applying the putty. The best putty is made of the best oil and whiting, and as a rule is good then according to its age, and the time it has been kept in a heap. Had we much glazing to do, we should like it to be made a twelvemonth; this accounts for the different prices of putty, though made in the same way. Allowance must be made for working and stowage room. For particular purposes, a little

white lead is useful for making the putty firmer. At one time we used to find our sash-bars as rough in the morning as the back of a hedgehog, and pieces of putty all over the glass. We found that the rats, hard-driven, had commenced on the putty. A little lead in the putty either was too much for them, or soon poisoned them. At one time we had to guard fresh-glazed sashes from their depredations.

ORNAMENTAL DEPARTMENT.

The sharp frosts will do good so far, they will enable us as soon as we can find time to clear up the pleasure grounds, and remove all the remains of the dead plants in the flower gardens. We hardly think many leaves will stand the first breeze after the frost of the morning of the 7th. Even the *Salvia fulgens*, a mass of scarlet a few days before, gave way on that morning. Dahlias being a mass of blackness which we could not find time to raise, they had earth piled up above their roots. We have lots of *Scarlet Pelargoniums*, &c., taken up and stored in sheds, with a little litter over them, but we have not had time to dress and put them away for the winter as yet; but they will keep safe enough for a time, though we always find they do rather better when taken up, cleaned, dressed, and boxed or potted at once. There has been, however, such a press of work needing attention, that we were glad to leave such things to a drizzling day, or a morning unsuitable to other work. Except the Dahlias, we have nothing out now that we care about keeping.

Centaurea candidissima.—We took up the last lot before the frost came on Friday, potted it, and placed it in a little bottom heat. We merely removed the large lower leaves, and left all the more upright ones untouched, and just reduced the ball enough to place it in a 6 or 7-inch pot. Those potted a fortnight ago are now showing the fresh roots at the sides of the pot already, and will soon be deprived of all their bottom heat. We have no doubt the others just potted will do equally well. The worst of it is, that such plants take up much room, and they are too large to use, without dividing, for edging purposes in another year. Small plants are best for that purpose, but we could not take cuttings from our out-of-door plants early enough this season. We shall try the following plan with some of our plants, each having several stems:—Take as much earth away from the roots as will permit these roots going so deeply that the base of these separate shoots may be covered with from 1 to 2 inches of sandy soil. These, with the assistance of bottom heat, will soon root, and then by the spring each of the shoots or stems composing the plant will also have emitted roots, and so the old plant may be cut up into as many parts as there are stems, much as may be done with a *Chrysanthemum* stool. These potted will make fine strong plants. When thus managed, extra care must be taken to prevent damp, as that would rot the stems. The plants of our main lot are potted rather high, but we could accomplish the above object when they are well rooted, and still have no danger of damp, by putting a rim round each pot and filling up from 1 to 1½ inch higher round the base of the stems. However treated, these old plants are better for the secondary or inside, than for the outside or edging row. Young plants are best for that purpose.

The old plants, if the centre is nipped off of each shoot after the days lengthen, will furnish side shoots by the beginning of March, which will strike freely in a hotbed, and which, hardened off, will be quite large enough for edging beds, &c. The difficulty of striking late in autumn, is owing to the liability of their damping-off, and especially when small succulent cuttings are taken. Hence we used to succeed well with it in July, taking then the side shoots from old plants, as above stated, and at that time needing no bottom heat. What cuttings we took this season after those made in spring, we could not put in until near the end of September, and as the season was varied we varied our practice. Even then we did not wish to injure the outline of the rows, &c., which were never better than they were this season, and, therefore, we selected with care some hundreds, not of tidy little bits, but of good stout stems, of the size of a goosequill, or larger in diameter. These felt firm and hard at the bottom. From these we carefully stripped off most of the leaves, leaving only the smallest at the top, and put them firmly in sandy soil in small pots, and gave them a little bottom heat in a pit, with top air night and day. Not one per cent. of these has damped as yet, and on examining them the other day a good proportion of them are filling the pots with roots. There need, therefore, be little difficulty with this plant, if either old plants can be saved, or strong firm-based cuttings can be taken. At the same time as we placed these cuttings in the slight hotbed, as we could spare no more room there then, we put a number of small pots with

one or two cuttings in each, on a dry shelf in a vinery, from which the Grapes were taken, and where they were fully exposed to the sun, which was very bright in October. Here they received no attention, except a syringing in a hot, dry day, allowing the water to lie a little on the shelf. Here, in the hot days, firm as these cuttings were, the heads would droop a little, but we do not think one has suffered from damping-off, and though few are rooting so freely as they are doing with bottom heat, all we have tried are callousing freely at the base, and will, no doubt, root generally in their dry quarters before the winter is over.

We meant to have tried this plant in the same pit with Calceolarias, but we can hardly do so now without taking cuttings from these fresh-potted plants. In fact, as we prepared a light for them, most likely we will do so. That light was prepared the same as lately described for Calceolarias, but knowing how brittle the roots of the Centaurea are, and how likely, if it had the chance, these roots would be to ramble, and thus increase the risk of breakage when moving, before putting on the 2 or 3 inches of sandy loam to place the cuttings in, we covered that one-light space with slates, so that the roots should not go down. We hope such cuttings will keep in a cold pit with a little protection in cold weather, and we are told that in many places it is as hardy out of doors as the Cineraria maritima. We mean to leave some large plants out, and, after banking them up with dry ashes, &c., see how the winter uses them. Such large plants as we have potted make fine centres for moderate-sized beds in summer, and suit most shades of scarlet and purple. Both the Centaurea and the Cineraria come in well with the brown Coleus, and they will suit some of the new Coleuses equally well, if these prove as hardy as the older kind.

Of course, if the cuttings stand in a cold pit, we cannot expect them to root speedily. We are quite satisfied if our Calceolarias do not make a root in eight or ten weeks. In fact, that time in a cold bed in winter will not excite the vital powers so much as a few days in a hotbed in spring. We have merely stated what has succeeded with us, and what we think might be tried. In taking up plants, though bottom heat is not essential, a little of it so far insures success that it encourages fresh rooting, and when the pot is full of roots the plants will stand wherever they can have light, and be kept rather dry. One chief element of success is the leaving entire all the upper small leaves.

Glass Cases.—We find that where we had no blinds the frosts have injured fine-leaved Begonias, Fuchsias, Heliotropes, &c., whilst where there were blinds and a glass front, even with a zinc roof, they were almost untouched. At one end, with a lofty glass roof, and backed by a wall of the mansion, even Coleus was not injured, and Heliotropes were blooming. Some day we hope to see a hot-water pipe through these corridors; but even iron stoves would keep them sufficiently warm, though attended with some little annoyance.

Took all Chrysanthemums under protection, and as soon as the weather is milder, will give the conservatory an overhauling, so as to have plants that will bloom more in winter. All climbers now need pruning-in, that more light may be given to the plants.

Several points we wished to allude to, but one we must not forget, and that is, to use as little water as possible in the present and succeeding month, and to spill as little as possible when watering. When plants are in beds, and a few need watering, it is best to lift these few out, and replace them when the pot has drained itself. To see water thrown about a house now, or a man watering cuttings in a frame with the rose of a watering pot, is enough to horrify one, and so is using cold water for any plant under glass, except, indeed, it is of the hardiest description. If glass is afforded at all, little or no cold water should be used now for some months, and slightly heated water will be a help to success.

One or two words more, as timely. See that all furnaces and flues are cleaned. We have just given ours a general overhaul. We would do it thoroughly much oftener than we do, if we could, though in the case of flues, &c., round boilers we do this more frequently than many. This cleanliness of flues round boilers is essential to economy in the use of fuel. The more soot there is round the boiler, the less heat is communicated to the water, and the more heat is taken up the chimney. Again, all joints of flues and pipes should be secured. Let it be remembered that the boilers and pipes of houses only used in winter, will not wear so long as those constantly in use. Many wrought-iron boilers will leak a little when the first fire is

lighted, but will be all right when the metal is kept a little expanded. Hot-water pipe joints will last longer when the joints are not quite full. We found this season, that in a conservatory the large flat pipes set upright, were far gone as respects the joints, so that they would not hold water. We could not take them out just now. Fortunately these pipes run in a bricked-in trench, and we made all tight for the present, by packing all round these joints pieces of brick and Portland cement.—R. F.

COVENT GARDEN MARKET.—NOVEMBER 11.

We have an abundant supply of both fruit and vegetables, but nothing that calls for any special remark. Prices are the same as last week.

TO CORRESPONDENTS.

* * We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely* to *The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

PRUNING FILBERT TREES (M. K.).—In Kent, where large quantities of Filberts are grown, the trees are pruned very severely, the framework of the tree being made basin-shaped, or like an inverted umbrella, the centre being open, and the outer edges may be about 5 feet high, and the same in diameter. About the middle or end of August all the gross shoots are pulled (not cut) out, leaving only the small slender twigs, which are in winter cut back spur-fashion, so that when the pruning is finished there is left scarcely any wood of the previous year longer than 1 or 2 inches; thus, with the exception of the Vine, no fruit trees so severely dealt with. Every season is not a favourable one for the Filbert, even in the district best suited to its growth. In general it does best on a dry soil with a porous stone-shatter subsoil. In such soils we have heard of upwards of a ton per acre, but this is considerably above the average. The same treatment applies to the Cob Nuts as to the Filberts—in fact, the Cobs are superseding the Filbert for market purposes, though certainly inferior for table.

ROSES ON EAST FRONT OF A HOUSE (A Lover of Flowers).—"Plant for the yellow Rose Gloire de Dijon, and One de Cazes for crimson. If more crimson Roses are wanted plant Charles Lefebvre and Maurice Bernardin. If another yellow Rose is wanted, plant Triomphe de Kennes. For climbing purposes procure them on the Manetti stock, and mix up half a barrow-load of decayed manure with the soil for each Rose.—W. F. RADCLIFFE."

HIGH CULTIVATION—LEAVES OF ROSES DYING (G. G.).—"High cultivation is intended to be synonymous with high manuring. Good cultivation may be applied to many other processes of gardening. The reasons why your high standards flourish, and your low standards die, may be that

the sorts depended on the short standards are usually the more delicate kinds. If they are delicate Roses, their being near very damp ground may affect them. The formation of the buds on the terminals is, perhaps, a last autumnal effort.—W. F. RADCLIFFE."

LONG SHOOTS OF ROSES (Idr).—"Shoots of Roses 3 and 4 feet long should be either tied to a stake or shortened one-third. Violent winds will otherwise break down these valuable shoots, the hope of next year. I am so open to the furious assaults of the south-west wind, that I am obliged to tie my Roses tightly. One shoot, the strongest, should in any case be tied to the stake. If the shoots are of Roses on the Manetti stock, those shoots will, if pruned back one-third, want no more pruning.—W. F. RADCLIFFE."

OLD CABBAGE ROSE—WORMS (Tuesday).—"Any of the large nursery-men who advertise in this Journal can supply the old Cabbage Rose Worms do no mischief to Roses, nor anywhere else. They, like moles, are natural drainers, and do good in strong land.—W. F. RADCLIFFE."

JAPANESE CHRYSANTHEMUMS (An Amateur).—These are varieties raised from *Chrysanthemum roseum punctatum*, introduced by Mr. Fortune from Japan. They are ornamental, and the flowers may be cut for vases. Mr. Salter, Versailles Nursery, Hammersmith, introduced them.

MINIATURE FRUIT GARDEN (R. E. A. P.).—Three shillings.

ICE STORING (Ene).—If you enclose four postage stamps with your address, and order No. 348 of our Journal, you will find in it a plan and description.

GRASS IN PLEASURE GROUND (H. L.).—As you mow it to make hay twice yearly, it will require mowing, and being part of your pleasure grounds, the best fertilisers to apply would be bonedust and guano fifteen bushels of the first-used and 3 cwt. of the other for each acre.

FEEN (C. T. H. Dorset).—A novel addition to the hundreds of varieties of *Scolopendrium vulgare*. Some of the spores being in a kind of calyx on the upper surface, it might be called calyciferens.

ROSES IN POTS (Rev. J. C.).—Paul's "Observations on the Cultivation of Roses in Pots" will suit you.

PROPAGATING IVY (J. T. S.).—The best way to obtain strong plants in a short time is to fill a number of 3-inch pots with sandy open soil, plunge them in the ground, layer into each a shoot of the current year's growth and, placing a stick to each pot, tie the shoot to it. The shoot should be covered with about an inch of soil in the pot, and secured with a peg. If you do this now or in spring, and keep the soil in the pots watered in dry weather, you will have well-rooted strong plants by next autumn, when the layers may be severed from the parents and planted out. If you cannot obtain layers, cuttings of the young shoots may now be taken—say from 8 inches to a foot of the growing point—and inserted about half their length in sandy soil in a sheltered situation, keeping them moist and shaded from hot sun in summer. They will be good plants by next autumn.

ECHEVERIA SECUNDA CULTURE (W. M. S.).—It requires to be kept from frost, but you may probably winter it safely in a cold frame if you keep it dry and afford protection from frost. The Echeverias are only hardy in dry, well-drained soil and warm situations; at least, such is our experience. We should be obliged by those having tried them stating whether they have found any of them hardy, and under what condition of soil, shelter, &c.

ORANGE TREE INFESTED WITH SCALE (L. L. B.).—The leaf sent us is covered with black fungus, and on the under side by the midrib there is seen the cause—namely, the Orange-tree cocoon or scale. It may be destroyed by washing the leaves on the under side with a sponge, using Clarke's Compound at the rate of 2 ozs. to the gallon of water, and as hot as the hand can bear. What remains after the washing may be used for syringing the tree, and the latter should then be washed so as to free the upper surface of the leaves of the black substance, using the Compound as before. The washing should be so complete as to entirely remove the black substance from the leaves and stems.

DESTROYING CRICKETS (Eight-years Subscriber).—Spread phosphorus paste on thin slices of bread in the same manner as butter, and rather thickly, and on the edges as well as the upper face. Put the slices at night in the places which the crickets frequent, removing them in the morning. It will poison all that partake of it, and they will be found near the baits in the morning. If they do not partake of that, mix half a pint of oatmeal, and a teaspoonful each of ground aniseed and caraway seed, with 1 oz. of arsenic, adding a little lard to make the mixture rather lumpy, but not so as to form paste. The whole should be well mixed and laid thinly on pieces of paper for the crickets to partake of it.

GRAPE IN AUGUST (A. B.).—To ripen the wood for young Vines, to start for fruiting next August, we would start them in December, and have the wood ripe and put to rest, by dryness and shade, by June. It requires considerable experience to manage this kind of work well.

ASPHALTING BOTTOM OF A VINE BORDER (Saml. Robinson).—We decidedly object to asphaltting the bottom of a Vine border with boiling tar and coal ashes. We should expect the Vine roots to be killed.

FUNGUS ON TAN (W. Kent, Dublin).—The fungus infesting the tan in your stove, is *Agaricus vulvaceus*, Bull. We know of no means of destroying it otherwise than by removing the whole of the material on which it is found growing. It is said to be poisonous.

REMOVING ROSES (Sunny).—We would not cut the roots of the Perpetual Roses you are removing unless they extended more than a foot from the collar of the plant. If they were much longer than that, then we would nip off the points. The stronger-growing kinds that you are to place against a wall we would cut in much as usual after planting this season, but next summer we would select shoots, and have them some 8 inches apart, and these we would merely top in the following autumn, allow the shoots ultimately to reach the top of the wall, and spur-in to a bud all the way up every year. Strong climbers do best on the young wood, with merely the point nipped out, and the old wood removed to make way for the young. We have seen shoots of *Noisette 4* feet long, covered with short flowering spurs from end to end. Your greenhouse will answer very well with an aspect due west, but in summer you may need shade for two or three hours in the afternoon.

INSECTS ON BEET LEAVES (F. and G.).—We could discern no insect on the fragment of Beet leaf you sent. There were some indications of a mining grub having been at work beneath the epidermis of the leaf, and

as you say the leaves of your Celery have been similarly injured, the marauders may be the grubs of the Celery fly, *Tephritis onopordium*. You will see it drawn and described in the "Cottage Gardeners' Dictionary." The only check is to pick off the leaves and burn them.

GARDENING (A Mechanic).—We cannot afford space for such details as you ask for. If you enclose four postage stamps with your direction, and order "Gardening for the Many," you will have it sent free by post from our office. After you have consulted that we shall readily answer any query to help you out of a difficulty, but we cannot undertake to teach the rudiments of horticulture.

PROTECTING ROSES—SUDDEN DECAY (W. Birkenhead).—"Unless the winters are very severe, there is no occasion to tie-up Roses with straw. If it is done, the air should be able to circulate through the covering. To 'overdo is often to undo.' The Roses, that had started into weak growth before protection, may have been injured, or they may have died from sudden transition. The straw bands should be removed gradually after having been slackened for a few days. Francois Premier may be more than replaced by Charles Lefebvre, Senateur Vaisse, and Madame Victor Verdier. Standard Roses frequently die from a knot in the stem which stops the circulation of the sap. I once had one that in summer 'went out' like the snuff of a candle. The roots were good. This puzzled me; I then cut the stock in half, where I saw a discoloration, like a burn, of the skin, and found the hard knot, or dead wood, which was the cause. When you buy standard Roses look well to the bark. Decay begins often before you receive them. Roses that start into weak growth after budding, should be cut down to one or two eyes in the spring following.—W. F. RADCLIFFE."

CAMPANULA PYRAMIDALIS CULTURE (Ama-onica).—We presume your plants are intended for specimens, that they were sown in April or May, have been potted off singly, and shifted as often as the pots become filled with roots, the pots being kept plunged out of doors in an open situation. They will now be strong plants in 6-inch pots, these being well filled with roots. We are obliged to suppose a case as you do not state what condition your plants are in. The pots being now full of roots, the plants should be shifted into 8-inch pots, providing free drainage, and using a compost of two-thirds loam from turf, and one-third leaf mould well reduced, and if at command add one-fourth old cow dung. If the soil does not contain enough of sand, one-sixth of sharp sand may be added. After potting give a gentle watering and place the plant in a cold frame, so that the foliage will not be more than a foot from the glass, plunging the pots to the rims in coal ashes. The soil should be kept no more than moist, and the plants cannot have too much air so long as they are protected from frost and heavy rain. In severe weather afford the protection of mats in addition to the lights. In February or March the plants will grow rapidly, and when the pots are full of roots, shift, before the roots become very much matted, into 9 or 10-inch pots, replace in the frame, keep well supplied with water, and give plenty of air. In these sizes of pots the plants may be allowed to flower, but if they are very vigorous and fill the pots with roots, shift them into 11-inch pots early in April, using a compost of two parts loam from turf, one part leaf mould, and one part old cow dung, with one-sixth of sharp sand. More water will be required as the plants grow; only give it when the soil becomes dry, but before the foliage flags. Manure water may be supplied once a week after the pots are filled with roots. The plants, when well grown, are fine objects for conservatory decoration, and splendid for borders.

REGONIA MANICATA CULTURE (Idem).—The Begonias you name are fine for winter or early spring flowering. They should from August have been kept rather dry, and in a cool temperature of from 50° to 55° at night. In January the temperature may be from 55° to 60° at night, and from 65° to 70° by day, with a rise from sun heat, and this, with a moist atmosphere, and a moderate amount of air, will bring them into fine bloom, which continues a long time. The flowers are very valuable for bouquets. It is remarkable that such free-flowering useful plants are not more generally cultivated. After flowering encourage a good growth, and that secured, gradually withhold water so as to induce rest, and then keep the plants comparatively cool and dry.

EUCHARIS AMAZONICA NOT FLOWERING (A Puzzled One).—We cannot account for your plants not flowering, except by the foliage not having been sufficiently exposed to light, and their not having been liberally treated whilst growing, and then well matured by being kept dry and fully exposed to light and air. The plant succeeds in a compost of two parts fibrous loam and one part sandy peat or leaf mould, with a free admixture of sand. Good drainage is necessary, and the plants should not be overpotted. Whilst growing afford a temperature of from 60° to 65° at night, and 70° or 75° by day, with a rise from sun heat, maintaining a moist atmosphere, and giving a plentiful supply of water. When the plants have made a good growth gradually withhold water, place them in an airy situation near the glass, and give no more water than is sufficient to keep the foliage from flagging, and to do this very little will be required. A temperature of from 55° to 60° at night, and 60° or 65° by day, will be sufficient when the plants are at rest, with an advance from sun heat.

DESTROYING COCKROACHES AND WOODLICE (T.).—Poison them with equal quantities of honey and arsenic mixed together and laid on strips of paper in places frequented by them. Immense numbers may be trapped, two teaspoonfuls of honey being employed for sweetening half a pint of water. This should be placed in an ordinary basin, which is to be set on the floor at night, with about four strips of wood or plasterers' laths reaching from the floor to the edge of the basin by which the cockroaches will ascend, and will then fall into the liquid, from which they cannot escape. Woodlice in rooms are best destroyed by placing a little short hay for them to secrete themselves in, and then pouring boiling water over the hay. This is best done early in the morning. If it be inconvenient to adopt this mode, take a boiled potato, wrap it in a little dry hay, and put it in a flower-pot, turn the pot on its side in the places where the woodlice are, and they will congregate in the hay about the potato. These baits should be examined every morning.

SCALE ON ORANGE TREES (F. G.).—We have not tried petroleum as a destroyer of insect life, but have tried paraffin successfully, but only for trees in a state of rest, and where there were no plants. We do not recommend it either for plants in leaf, and especially under glass. See answer to another correspondent in to-day's Journal, as to the destruction of scale on Orange trees.

GLADIOLI PLANTING—VARIETIES (*D. H. S.*).—The best time to plant is from the beginning to the middle of March according to the weather. They may be planted in April, but those planted early produce the largest and finest spikes and flowers. A few select and not very expensive varieties are—Calendulaceus, Neptune, Rebecca, Le Ponsin, MacMahon, Ophir, Archimedes, The Colonel, Oracle, Madame Basseville, Madame de Vetry, Dixie, Edulia, Dr. Lindley, Stephenson, Princesse Clothilde, Goliath, John Waterer, Tippe Sahib, Berenice, Marie, Clara, Brencchleyensis, Aglae, Dr. Andry, Mrs. Lombard, Zoe, and Mrs. Siddons, all strong growers. Of lesser growth—Adonis, Fanny Rouget, Mars, Pluton, Junon, Du Candolle, Lactia, Reine Victoria, Lemonnade, Walter Scott (Standish), Madame Duval, Diane, Isoline, Charles Dickens, Peter Lawson, Marie Dumortier, Stuart Low, Lady Morgan, Madame Damage, Achille, Eugénie Verdier, Napoleon III., Cardinal, Rembrandt, Flore, Samuel Weymouth, and Ceres.

AGANTHUS UMBELLATUS CULTURE (*Idem*).—It succeeds in a compost of two parts turfy loam and one part leaf mould. The best time to repot is immediately after flowering, or when in active growth. The plants may be placed out of doors in May, and should have an abundant supply of

water; and if the pots or tubs are not plunged, they may be placed in saucers filled with water. The plants should be housed before severe weather sets in, and merely protected from frost, and no more water should be given than will keep the foliage fresh. A light and airy situation should be given. They flower best when under rather than over potted.

ARTIFICIAL MANURES (*Idem*).—We tried "Paxton's Horticultural" and "Carter's Fertiliser," and consider them beneficial to plants.

NAMES OF FRUITS (*A. D. A.*).—The box sent by simple post was charged 4s, so we declined receiving it. (*A. B. D., Rule*). Your Apple is the Scarlet Pearmain. (*Centurion*).—All that we can identify are: 5, Siberian Harvey; 9 and 10, Calville Blanche; and 11, Cox's Golden Drop. There is no Apple named "French Pippin;" 2 is not "Warwickshire Pippin." (*Lambert, Dublin*).—1, Duc de Nemours; 2, Louise d'Orléans. The Apple we do not recognise. (*C. T. H., Dorset*). 1, Beurre de Rance; 2, Beurre Diel; 4, Alfriston; 5, Wheeler's Russet; 7, Russet Nonpareil.

NAMES OF PLANTS (*Nemo*).—We cannot identify plants from leaves only, we require flowers. (*W. L.*)—Liquidambar styraciflua, or Sweet Gum Tree. (*Dr. Bryant*).—Coccoloba platycladon.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the week ending November 10th.

DATE.	BAROMETER.		THERMOMETER.				Wind.	Rain in inches.	GENERAL REMARKS.
			Air.		Earth.				
	Max.	Min.	Max.	Min.	1 ft. dp.	2 ft. dp.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

VULTURE-HOCKED BRAHMA POOTRAS TRIMMED, AND THE NO-APPEAL RULE.

THE hock question has during the past season reached a stage which seems to me imperatively to demand that a stand be made against practices which are beginning openly to prevail, and which must have a tendency to drive honourable people out of the fancy. I have been appealed to on several occasions to take the matter up; and now that the large shows are fast approaching, I hope attention may be drawn to the matter with some chance of success.

On two occasions during the past season Mr. Hewitt has given the first prize to a Brahma cock, which when "in a state of nature," or "undressed," or whatever be the most delicate term to express being untampered with, I know to be hocked almost to the ground. Now, I mention Mr. Hewitt's name out of several instances known to me, not to cast the shadow of suspicion on the best judge we have, but for the express reason that the question may be regarded as apart from all errors or faults of judging at all. Nay, I may add that the same bird had previously deceived Mr. Teebay, and would very likely have deceived me also had I only seen him in the pen; but having happened to see him in his own yard I was perforce made aware of the deception.

Having thus expressly exonerated Mr. Hewitt, I will mention one more case in a pair of pullets which won many prizes last season, and were in like manner shamefully trimmed. When I first saw them I had no time to examine; and so artfully was the operation performed, that, when a friend expressed his opinion that the birds must be hocked on account of their heavy feather, I replied, "Nonsense!" for the exhibitor stood very high in the poultry world. But meeting the same birds again I found they *were* hocked, the apertures being distinctly visible from which the feathers had been pulled!

Now, I admire heavy feather and a well-covered hock, and I dislike vulture hock; but this question has nothing to do with such points at all. It is a simple matter of honesty and fair dealing. The exhibitor of the pullets I refer to has sold many eggs, and all of which I have any knowledge have produced chicks hocked to the masthead. I even know two instances in which birds were purchased of him, and developed the hock after changing owners. Now, in the face of such practices I desire to ask your editorial opinion on the following questions, and if Mr. Hewitt would add the weight of his opinion also, those concerned would be still more grateful.

1, No judge can be expected always to detect such swindles;

but if, after the prizes are awarded, I or any other individual can prove, either by ocular demonstration or unimpeachable evidence, that hocks have been pulled in a prize bird, ought not such bird to be by such fact disqualified, the name exposed, and the other mentioned birds below promoted one stage each in consequence, without troubling the judge about the matter? I think so.

2, But if this be decided in the negative, are we to conclude that all may trim, so that all may compete on the same level, and honest men have some chance against thieves? I hate the practice, as destructive of all security in breeding, but this would be at least fair and open.

These are questions I should like answered. I do not wish to put the responsibility on the judges, or to open disputes over a prize; but any one who has kept Brahmas and been his own poultryman, as I have, can in most cases from the "set" of the feathers on the thighs tell a hocked bird, and inspection will confirm the suspicion if just. There will be plenty of evidence. And I submit that to disqualify absolutely in every case of this character need by no means open the door to general wrangling, while it is the only way to save our "fancy" from a fast-increasing knavery, which is akin to the boiled-egg business we heard so much of a while ago.

Will you kindly give your own and, if possible, Mr. Hewitt's opinion on this matter? and by so doing oblige many besides—**NEMO**.

[No honest mind can have a doubt upon the subject. ALL TRIMMING, EXCEPT DUBBING GAME FOWLS AND GAME BANTAMS, IS FRAUDULENT; when detected to the satisfaction of the committee the birds trimmed should be disqualified, the name of the exhibitor published, and the prize awarded to the trimmed birds either forfeited or given to the next most meritorious pen. Holding this opinion, we need not express any opinion on the second question.—**EDS.**]

FRAUDS AT POULTRY SHOWS.

KNOWING the strong feeling of disapprobation which you entertain with regard to underhand practices in the preparation of poultry for exhibition, I venture to address you on this subject.

It appears to me that all exhibitors who are determined, cost what it may, to adhere rigidly to upright dealing, should unite, and endeavour to put down practices which otherwise must eventually drive honourable competitors from the field. I allude more especially to those trimmings of combs (not Game), dyeing of feathers, extraction of faulty plumage, &c., which from their exceeding cleverness might easily escape the detection of the most scrupulous judge, especially amidst the multitude of birds in very large shows. It would be really

distressing if poultry shows, which of late years have become so deservedly popular, and which add so much to the enjoyment of many country homes, should fall out of the hands of honourable people, and be abandoned to the less scrupulous.

I venture to suggest what seems to me might to a great extent remedy this evil. Let all committees of poultry shows insert on their forms of entry a separate paragraph to the following effect, this to be signed separately by each exhibitor:—

"I hereby affirm that all birds exhibited under my name at the — Show, date —, are my *bona fide* property; also that no bird of mine has been, to my knowledge, in any way trimmed (with the exception of combs in Game fowls).

"Signed — (Name of exhibitor).
A fine of £20 will be enforced if the above certificate is found to be falsely signed."

I merely throw out these few suggestions to be improved upon by the various committees of poultry exhibitions.—AN HONEST EXHIBITOR.

[We think that each exhibitor might be required to sign a short memorandum of an agreement binding himself to forfeit a specified sum if the birds he exhibited were trimmed or dyed.—EDS.]

POULTRY SHOW DETAILS.

THERE are many things connected with poultry shows, such as entrance fees for various classes of fowls, the length of time shows are held, and several other details, which require amendment, and I should be glad if exhibitors who are likely to be at the forthcoming Birmingham Show, would meet together, and discuss the various subjects which would be brought before them. I am not much acquainted with Birmingham, but would suggest that we meet at some suitable place, say on the Saturday or Monday evening. If any one would name a likely place to meet, I would inform exhibitors by an advertisement in the next number of the Journal.—J. WALKER, *Haya Park, Knaresborough.*

IPSWICH SHOW.

I QUITE agree with your remarks respecting the position of pens, roup, &c. Fowls with roup ought to be rigidly excluded. At Stowmarket the Dorkings were frightfully affected. Why not make a rule accordingly? I should also like to see the obnoxious entrance fee to this and all other shows abolished. I would likewise suggest the propriety of having generally a scale of charges for pens adopted—thus, one pen 5s.; two, 8s.; three, 11s.; four, 14s.; five, 16s., and there stop, to begin again at the same rate. Lastly, surely a plan might be adopted to prevent shows clashing as they now do.—HENRY P. LEECH.

[The remarks about the "too late" pens, and the man being in the room when Mr. Hewitt was judging, should be sent to the Committee. The explanations might be satisfactory, and then no one would be annoyed unnecessarily.—EDS.]

I CONSIDER your report of the Ipswich Show very good, as far as it goes, but it scarcely touches the Pigeons. As you observe, the quantity and quality of the poultry were excellent, and the Committee is deserving of praise; but although there was such an improvement in the poultry, the Pigeons were not so well represented as last year. Not only were the entries twenty-one pens less than last year, but the quality of the birds was not equal, and the Carriers and Pouters, being placed below, were seen to great disadvantage, although several of them were, as you justly observe, some of the best birds in the fancy. It must, however, ever be quality rather than quantity that makes a first-class show. Last year there were thirty-seven pens of the three higher classes of Pigeons, against twenty-three of this year; but in the variety and selling classes there was an increase. This arises through showing Carriers and Pouters in pairs, instead of as single birds. It is almost impossible to get a first-class show of Pigeons where Carriers and Pouters are to be shown in pairs, because several of the best breeders of those varieties never show except where prizes are offered for single birds, and the increased number of entries will generally meet the extra prizes. I was surprised after what had appeared in your Journal, to see that one exhibitor had a prize awarded him for two cocks.—L. WREN, *Lowestoft.*

BIRMINGHAM POULTRY SHOW.—The entries for the Birmingham Cattle and Poultry Show, which commences on Saturday,

28th inst., are unusually numerous. The entries of poultry amount to 2312 pens; and of Pigeons to 445.

SHEFFIELD COLUMBARIAN SOCIETY'S SHOW

THIS, the tenth annual Show, was held at the New Inn on the 2nd inst.

BIRDS OF 1868.

CARRIERS.—First and Second, T. Colley, Sheffield. Third, J. Deakin, Burrowlee.

PUTERS.—First and Second, H. Brown, Walkley. Third, W. Harvey, Spring Vale.

TUMBLERS.—First and Second, H. Brown, Walkley. Third, T. Wilkinson, Walkley.

FANTAILS.—First, T. Wilkinson. Second, H. Brown, Walkley. Third, G. Wostenholm, Sheffield.

OWLS.—First and Second, T. Wilkinson. Third, H. Brown.

TURBIS.—First, T. Wilkinson. Second and Third, R. Siddall.

DRAGONS.—First and Second, W. Harvey, Spring Vale. Third, — Deakin.

ANY VARIETY.—First and Third, E. Brown. Second, — Bower.

BIRMINGHAM PHILOPERISTERON SOCIETY.

FLW exhibitions have ever shown a more excellent commencement than that held on the 4th and 5th inst.; it was decidedly one of the best Shows of Pigeons we have ever seen in this locality. The arrangements were excellent, and the Exhibition was attended by the public in larger numbers than was expected. Scarcely a single class was deficient in quality, and the competition in most of them was unusually severe, consequently a complete success was secured. Perhaps the best classes were the Carrier, Pouter, Fantail, Dragon, and variety classes, though almost every one was excellent. Mr. Yardley, who, as a judge, contributed some pens to the Show, did not compete, though exhibiting a first-class cage of twenty-one Short-faced Tumblers of great beauty and value, which were generally admired. Several other varieties shown, but not for competition, by Mr. Yardley, contributed not a little to the interest of the Show. The class for Antwerps was of decided excellence, as were the Carriers, Jacobins, Fantails, Trumpeters, Owls, and Turbits; the Barbs, Magpies, Swallows, Ice Pigeons, Nuns, and Satinets, being also very good. With so good a beginning, we have little doubt that at a future date this Society will secure a very large amount of popularity.

BIRDS OF 1868.

CARRIERS.—First and Highly Commended, G. F. Whitehouse, King's Heath. Second, J. E. Cleveland, Birmingham. Third, F. F. Foster, Birmingham. Commended, T. Robson, Penkridge; G. F. Whitehouse.

PUTERS.—First, Second, and Third, F. F. Foster.

ALMONDS.—First, Second, and Third, T. Baldwinstein, Derby.

BARBS AND BEARDS.—First and Second, J. W. Edge, Aston New Town.

SHORT-FACED TUMBLERS (Any other variety).—First and Second, T. Baldwinstein. Third, G. F. Whitehouse.

JACOBINS.—First and Second, J. W. Edge.

FANTAILS.—First, G. F. Whitehouse. Second, F. F. Foster. Third, J. W. Edge.

TRUMPETERS.—First and Second, T. Robson.

OWLS (Foreign).—First, P. Graham, Birkenhead. Second, C. Barnes, Birmingham.

OWLS (English).—First, Withheld. Second, C. Barnes.

TURBIS.—First, T. Robson. Second and Highly Commended, C. Barnes. Third, J. W. Edge.

BARBS.—First, Second, and Third, F. F. Foster.

NUNS.—First and Second, G. F. Whitehouse.

DRAGONS.—First, Third, and Highly Commended, G. F. Whitehouse.

Second, J. W. Edge.

MAGPIES.—First, T. Robson. Second, J. W. Edge.

ANTWERPS.—First, J. E. Cleveland. Second, F. F. Foster. Third, C. Barnes.

ANY OTHER VARIETY.—First and Second, J. W. Edge. Third, C. Barnes.

Commended, G. F. Whitehouse; J. W. Edge.

BLUE EAGLES.—First, J. W. Edge. Second, A. Walthew, Birmingham.

BLACK SAMBLES.—First, J. W. Edge. Second, — Bartlett.

SADDLES (Any other colour).—First, A. Walthew. Second, H. Sproston (Red).

MOTTLES.—First and Second, J. W. Edge.

ROSEWINGS AND REDBREASTS.—First and Second, J. W. Edge.

BIRDS OF ANY AGE.

CARRIERS.—Cocks.—First and Commended, G. F. Whitehouse. Second, G. Sturgess, Leicester. Hens.—First, C. Barnes. Second, G. Sturgess. Third, J. E. Cleveland.

PUTERS.—Cocks.—First, G. Sturgess. Second, F. F. Foster. Hens.—First, G. Sturgess. Second and Highly Commended, F. F. Foster.

ALMONDS.—First, T. Baldwinstein. Second, F. Graham, Birkenhead.

BARBS AND BEARDS.—Prize, F. Graham.

SHORT-FACED (Any other variety).—First, F. Graham. Second, Withheld.

FANTAILS.—First, J. W. Edge. Second, F. Graham. Highly Commended, F. F. Foster.

OWLS (Foreign).—First, F. Graham. Second, J. W. Edge.

OWLS (English).—First, F. Sale, Derby. Second, J. W. Edge. Third, C. Barnes. Highly Commended, F. Graham.

TURBIS.—First, F. Sale. Second and Third, J. W. Edge. Commended and Highly Commended, C. Barnes.

BARBS.—First and Second, F. F. Foster.

NUNS.—First, F. Graham. Second, G. F. Whitehouse.

DRAGONS (Blue).—First, F. Graham. Second, J. Walters, Derby.

DRAGONS (Any other colour).—First, F. Sale. Second, J. W. Edge.

MAGPIES.—First, F. Sale. Second, F. F. Foster.

ANTWERPS.—First, J. W. Edge. Second, J. Walters.
 SWALLOWS.—First, G. F. Whitehouse. Second, P. Sale.
 ANY OTHER VARIETY.—First, F. Graham (Runts). Second, Withheld.
 ANTWERPS.—Cocks.—First, F. F. Foster. Second, Bartleet, Birmingham.
 Third, J. E. Cleveland. Highly Commended, J. E. Cleveland; C. Earnos; J. W. Edge.
 BLACK BADGES.—First, — Bartleet. Second, J. W. Edge.
 BLUE BADGES.—First, J. W. Edge. Second, A. Walthow.
 BADGES (Any other colour).—Prize, J. W. Edge.
 BLUE SADDLES.—First and Second, J. W. Edge.
 BLUE SADDLES.—First, A. Walthow. Second, J. W. Edge.
 MOTTLERS.—Prize, J. W. Edge.
 ROSEWINGS AND REDBREASTS.—First, J. W. Edge. Second, A. Walthow.
 TUMBLERS (Any other variety).—Prize, — Bartleet.

The Judges for Fancy Pigeons, were Mr. Edward Hewitt, and Mr. Henry Yardley, both of Birmingham; and for the Flying Tumblers, Mr. William Beardmore, and Mr. H. Harvey, also of Birmingham.

ASTHMA IN CANARIES—NORWICH AND YORKSHIRE VARIETIES.

ASTHMA in Canaries arises from two causes—either from the bird being kept in a room where the air is impure, close, and too hot, or from a disordered stomach. The way to cure it is to feed with soaked rape seed, and bread and milk, giving the patient twice a-week two drops of castor oil, and linseed tea instead of water to drink. Birds cannot endure an impure air. More birds are killed by being hung up in a warm room where gas is, when they are “putty,” than people imagine. If you keep them from draughts of cold air, it is really surprising the amount of cold they will bear uninjured. I have known the water frozen in prize birds’ drinking glasses. Let “CANARIENSIS” put his asthmatical birds in a large cage with wooden ends and top, give them plenty of cold water to bathe in, bread and milk and soaked rape to eat, no green food—the worst thing, I think, for cage birds—and if anything will cure them that treatment will.

There is as much difference between a Norwich and Yorkshire Canary as there is between a Chinaman and a Scotchman. Good Norwich birds are never seen except in a few hands, and Derby is where they are turned out in the best form. The secret of the high colour (and it is a secret), is only known to about twenty men in England (I do not mean dyeing or anything unfair), and I do not suppose one of them would tell for £500.—HOWARTH ASHTON.

YORK CANARY SHOW.

I saw some very good birds exhibited at York, but I was not satisfied with the awards; I do not, however, blame the Judges, but the system on which they based their decisions. For instance, in the Dark-crested class the first and second prizes were given to two inferior-bred birds, marked, wretched in colour, but possessing good crests. The entries in this class were numerous, and amongst them some beautiful high-bred good-coloured Norwich birds. Mr. Tomes sent a lovely Buff bird, Mr. Blakston a pair, the first and second at North Ormesby Show, and when I say that I sent a beautiful clear Yellow first-prize bird at Sunderland, and another a third-prize bird, it is sufficient testimony of their quality and all of them having very good dark crests. Now, I think, if the judge at an agricultural show awarded the prize to a cow in the long-horned class simply because she had the largest and longest horns, quite overlooking the quality of the animal, it would be as sensible as giving the prize to a bird for the crest alone, and entirely disregarding all other points. I wish to know if a crest should overrule all other points and quality. I quite agree that the crest should rank as the most important point, but I think other qualifications should also be taken into consideration by a judge. The schedule states Class N, Dark-crested Canary.

The same remarks similarly apply to the Light-crested class and the Lizards; one single point seemed to overrule all others.

I also wish to know if, after the judges have awarded a prize, and the show is open to the public, the secretary has any right to remove the prize card and place it on another cage? The case is—I made an error in entering a Buff Belgian bird in the Yellow class. According to the rules this disqualifies me from taking the prize (the money I suppose); but on entering the room I found my bird placed in the right class, and removed from the Yellow birds, and the first-prize card attached to the cage by the Judges. After the Show was opened this card was taken away and placed on another cage. The rules state “There is no appeal from the decision of the Judges,” and my bird was awarded the first prize by them. Should not the card

have remained where it was on my cage? or does not the fact of the officials removing the Buff bird from its number in the Yellow class, and placing it amongst the Buffs and in the right class, correct the error I made in the entry, and entitle me to the prize?

The office of judge is always a thankless one at best, and I will here thank the Judges on this occasion for their courtesy and the friendly way they received any criticisms made to them. I write especially to gain information myself, and in the hope that some day our Canary judges will possess standard and uniform rules to go by. It was the first Show held in York, open to all England, &c., and allowances must be made; but I have no doubt the experience gained will enable the worthy President and Secretaries to get up a very superior exhibition of birds next year. I for one shall hope to support them, as I have no other motive in writing than the object of benefiting Canary shows and Canary judges by obtaining a system of standard and uniform rules. I suggest a conference at the next Sunderland Show.—W. DINSTEY SKELTON, JUN., *Leeds*.

[We think the Judges did wrong when they removed the Canary to the class in which it ought to have been exhibited; and that the Committee were right in removing the prize card. By being exhibited in the wrong class the bird was disqualified, and though from the judgment of the Judges “there is no appeal,” that judgment is restricted to the merits of the birds. If a bird is exhibited in a wrong class they should pass it over unnoticed; and if the Judges in any way exceed their powers, the Committee only do their duty if they correct the mistake.—EDS.]

TRANSFERRING BEES.

I HAVE about sixteen stocks of bees, which did pretty well on the depriving system this year. I found, however, great difficulty in preventing some of the stocks, which are in small straw hives, from swarming, and as these are also getting old, I am anxious, if possible, to transfer them to Woodbury bar hives, which, from experience, I find the best.

To do this, I purpose next spring reversing the hive, and having fixed it with the mouth of the hive level with the former landing board, placing a temporary bottom board, with a hole cut out nearly the size of hive, and over it a bar hive. By this plan I think the stock will leave the old hive gradually, while it will leave them time to store their new home and bring out the brood, which otherwise would be lost. When, from inspection, I find them well settled in the bar hive, I can cut off the communication between them and shake out the bees still in the old hive, when they will, of course, join the others. From your experience can you tell me if this is likely to succeed? As I have not nearly enough of guide comb, and cannot buy it, perhaps you can tell me if your opinion is the same as some of your correspondents, as to the use of wax sheets. Also if the whole frame must be filled with them, or only a strip at top?—SUPER.

[Although we have had no direct experience of the plan which you propose, we think it will fail in this way:—The bees of the inverted hives will, probably, take possession of the bar hives, which you propose placing over them, just as they would take possession of any other kind of super, and proceed to fill them. The combs which they place therein are, however, likely to be for the most part drone combs, or combs with elongated cells, in either case quite unfit for breeding, which will, probably, continue to be confined to the lower hive and in this way your intention will be frustrated. We should much prefer transferring the bees and combs directly into frame hives in the following manner:—Towards the latter end of April, or as soon as the stocks become populous, and during the forenoon of a fine day drive all the bees into an empty hive, and put them on their accustomed stand. Take their original hive in-doors, and cut out all the combs whole. Fit these into frames, and support them therein by strips of wood three-eighths of an inch wide, and one-sixteenth thick, tacked at the top and bottom, two on each side of every comb, and by zinc clips when necessary. Thick combs must be pared down, but take care that the cells on either side are of equal length, also that the “partition wall” is in the centre of each bar. Crooked combs should be set straight, and if not sufficiently pliable may be slightly warmed before the fire. It will be found convenient to remove the projecting Woodbury rib from the bars, and the bees will attach their combs to them with greater facility if their under surface be coated with melted wax. Having completed the job and arranged the combs in

their new apartments in the same order as that which they occupied in their old one, deepen the hive by the addition, on the top, of another, from which the frames and crown and floor boards have been removed, set it on the old stand, and knock out the cluster of bees into the upper hive on the top of the frames of the lower one, putting on the crown board immediately. Next morning take away the inserted hive, and the day after that remove the supports from all the combs which the bees have fixed. If any are not secured, their supports may be left until they are fastened. If, however, you consider the combs too old for transferring, you may permit the stocks to swarm naturally, and twenty-one days after the issue of the first, drive out all the remaining bees and add them to one of the swarms, appropriating to your own use the combs and their contents, which will at this time be found nearly, if not entirely free from brood. Or the same result may be brought about artificially by driving all the bees into empty hives in the middle of a fine day during the month of May, and establishing them as swarms in Woodbury hives on their old stands. Their deserted habitations should then be put in the place of other strong stocks (which must be removed to new positions), and dealt with twenty-one days afterwards in the manner already described. Strips of artificial comb, or embossed wax about an inch wide, are excellent substitutes for guide combs.]

WAX SHEETS—HIVES QUEENLESS—QUEENS UNPROLIFIC.

To be successful with wax sheets they ought to be deeply impressed, and of one uniform thickness, otherwise the apiarian will find to his or her loss, that bees placed amongst plain sheets will at once commence excavating the bases of the cells, and in so doing will cut through the wax instead of building on the already-laid foundation. The waxen sheets, perforated in this way as if by so many shot-holes, will ultimately fall, and instead of appearing paragona of neatness, will become masses of almost worthless combs, fit only to be remelted. This, the experience of myself, as well as others, is directly opposed to the conclusions of "APICOLA," (see page 199).

I have also been puzzled to account for his queenless stocks building worker instead of drone combs. If this took place with plain sheets it is a remarkable fact; if with impressed sheets it is a proof of their superiority over plain ones, and controverts his own argument. What is said of the bees rejecting waxen sheets, and taking to combs in preference, proves nothing against them, since it is natural for bees to take to the farthest-advanced pieces, showing their sagacity in so doing. Instead of my bees rejecting impressed sheets they are passionately fond of them, and I had this season to remove several unoccupied hives that had been furnished with sheets and were standing ready for swarms in the bee house, owing to the bees from some storied hives taking possession of them.

"APICOLA" goes on to say, that "The expense is, however, a great objection, the makers charging 6d. a-piece for them." He speaks it without taking into consideration the pains that are required in making these not once only, but, perhaps, some of them requiring to be remade several times ere a marketable sheet can be obtained. Besides, when sheets are ordered, it often happens that six or twelve are the most that are wanted, and when packing and packing-box is taken into consideration, 6d. a-piece is not too much for them. When many dozens of these sheets are ordered at a time, they can be had at a considerable reduction. As I am now in want of some hundreds, and cannot even purchase wax at that rate, I should be glad if "APICOLA" would communicate with me with the view of supplying me with wax sheets of the dimensions which he states, at 1d. each, or even a fraction more, but they must be sheets that will please one who makes them.

I should also be glad if "APICOLA" would explain the circumstances under which his queenless hives built worker instead of drone comb. Through all my experience I never yet found a queenless stock build worker comb, but, on the contrary, have known queenless bees transform worker to drone comb, and stocks build drone combs readily when their queen relaxes laying. It is, indeed, only by selecting fertile queens, keeping them laying, and avoiding waste of eggs, that surplus drone combs can be avoided. A young queen whose bees build drone combs ought to be destroyed, as it shows either a defect in her organs, or that she is not prolific, in which case the hive will go to ruin, unless a change of queens be effected. It is, in fact, best to examine every hive containing a young queen, lest

she should not be prolific, since otherwise the defect may not be detected until a new queen has been raised, when it is too late for impregnation, and the hive may in this way be lost.

The instinct which prompts bees to raise young queens whenever their own queen is reluctant to lay, is not always attended with success, as, for example, a perfect young queen may only be taking a rest that nature demands, when the bees commence raising others, and should one of these be allowed to reign, and the season be far advanced, the stock will be lost. "Feed your bees in autumn, and you will have good hives," is a common saying. This, however, only holds good when they are fed early. August is the best time, as it affords the bees the opportunity of raising young queens ere all the drones are killed, in case the old queen or even a young one be nearly exhausted. Queens which cease laying in September, or even sooner, and do not recommence until March, often produce the best hives, as in this case their powers are not impaired by continuous laying, and then, as with poultry, they lay constantly for the time, and changes of queens are not so frequent. Bees when fed so late as October, naturally commence breeding, and the young ones thus produced often do not have a favourable opportunity for airing until the spring months, by which time they are so swollen by long confinement that they are almost sure to be lost, and present the appearance of dysentery. Besides this, bees that are late-fed do not seal up their honey, so that their hive instead of being a comfortable dwelling becomes a miserable one, and many a queen which might have bred on until the spring, becomes dethroned, and is succeeded by a young princess.—A LANARSHIRE BEE-KEEPER.

MICROSCOPICAL INVESTIGATIONS INTO THE NATURE AND ORIGIN OF FOUL BROOD.

WITH great pleasure I respond to the invitation of the "DEVONSHIRE BEE-KEEPER," in page 311, to give my opinion of the theory advanced in the very able and interesting paper of Dr. Preuss. At the same time it is with considerable diffidence that I venture to make any remarks on the subject, inasmuch as I am neither a fungologist nor an adept in the use of the microscope. I can neither confute nor corroborate the truth of the appearances which foul brood has presented under his manipulations; but I may remind the readers of "our Journal" that Mr. Edward Parfitt, in his investigation of foul brood, arrived at results apparently different from those of Dr. Preuss. The former discovered minute animals in the material submitted to him for examination, the latter appears to have found fungi only.

Now, I have always regarded fungus as an effect, and not the cause of decay. Its origin and development depend in a great degree upon influences which may be called atmospheric. For example, the past exceptional season caused the Mushroom fungus to spring up in places where, perhaps, no one living ever saw it before. And reasoning from analogy, I would say that the fungus in disease owes its origin and development to disease, but does not occasion it. I doubt much whether it will even live where the vitality of a subject is perfect and its health unimpaired. If sporules attach themselves to larvae and multiply in such numbers as to be inconsistent with the continued life of the organism on which they are discovered, I expect these deposits have found a soil prepared for their reception. The subtle influence which occasions death and decay must have been previously at work. We are all anxious to know what that mysterious agent is; and I cannot help thinking it is a miasma or poison generated by putrescent bodies, that have died at a particular stage of existence, under favourable states of atmosphere. I am therefore of opinion that the vital principle in a subject must have been injured prior to the fungus taking possession of it. The views of Dr. Preuss are nearly identical with those propounded by "G. F. B., Spalling," in the Journal of September 1st, 1863.

If sporules attach themselves to the feet of bees, how can a swarm emanating from a hive virulently affected with foul brood escape carrying the disease along with it? But I have witnessed on various occasions perfectly healthy colonies go forth from habitations in which the plague was raging. Besides, we should expect a fungus to die when the material on which it subsists has been exhausted. Is not its pabulum gone when the brood combs are excised on the approach of winter? but in an infected hive the virus remains after every comb has been extracted. It even adheres to it for years when not neutralised by some such agent as chloride of lime. A putrescent body is no doubt a fitting nidus for sporules; and

I do think that sealed-up larvae, dying from whatever cause, and continuing unremoved, have much to do with the introduction of the foul-brood pest into our hives. Those of a certain age very soon pass into a treacherous state of consistence, and adhere to the cells, giving forth an offensive odour; and it is in these putrescent bodies I believe the germ of disease is to be found. At all events, in making use of combs in which I had allowed the brood to perish of cold and rot, I have found most unsatisfactory results follow. This was even the case when I was at due pains to clean out every cell that had become putrid. Foul brood generally followed, certainly not with virulence at first, but as an evil that would go on increasing. Now, cells of the description referred to are frequently to be met with in spring and autumn in hives where the population is scant. I have made several direct experiments with combs from which I had extracted putrid brood which had been allowed to die of cold, and I have no hesitation in saying that healthy hives were tainted by their introduction.

Notwithstanding all I have said, it is still possible that I may have been making use of previously-infected combs, in spite of the most painstaking examination.—R. S.

[With regard to the microscopical examination of foul brood which Mr. Edward Parfitt so kindly undertook at my request, and the result of which was published in "our Journal" on the 24th of November, 1863, I may now state that his investigations were subsequently repeated by competent observers, who came to the conclusion that the minute "animals" figured by that gentleman were merely vibrations of some kind. These are a family of very minute organisms, well known to microscopists as being present in all or nearly all infusions of decaying or putrid substances, as well as in the purulent matter of tumours, and even in the tartar of the teeth. Their nature, however, is not as yet clearly understood, it being doubtful whether they are animal or vegetable; but it seems to be certain that they are the effect and not the cause of disease, and this I fancy is most probably the case in respect of the fungi discovered by Dr. Preuss.

I have myself had no experience of swarms issuing from hives infected with virulent foul brood, and in the face of such an announcement it may appear almost presumptuous in me to doubt the correctness of so accurate an observer as "R. S." Having regard, however, to the pestilential character of the disease, I am almost disposed to question whether a perfectly healthy swarm can ever issue from a virulently diseased stock. It is, of course, just possible that a tainted swarm issuing with a virgin queen, and placed in a pure hive, may completely purge itself of the infection by reason of the period which must elapse before the commencement of egg-laying serving to exhaust the virus in the same manner as the three or four days of penal discipline and inanition, which are recommended by Dzierzon; but I cannot but believe that however healthy such a swarm may appear at the outset, it will generally be found that the disease is only latent, and that in the vast majority of instances it will sooner or later reassume all its former virulence.

I am, moreover, firmly of opinion that perfectly healthy brood, no matter what its age may be, can by no possibility be made to pass into that peculiar kind or phase of decomposition in which it assumes a brown colour and a treacherous state of consistence, adheres to the cells, and gives forth an offensive odour. All these I regard as unmistakable and indubitable evidence of the presence of virulent foul brood, and I would on no account admit within my apiary either the bees or the combs from a hive in which I found a single cell of this description.

The perusal of the foregoing article from the pen of my valued friend and correspondent leaves, therefore, upon my mind the painful impression that nearly all—perhaps, indeed, every one—of the stocks which he possesses, or to which he has access, are more or less tainted with foul brood; and that from this cause, in spite of all his laborious and painstaking examinations, the results of his very laudable experiments and investigations into the nature and origin of foul brood have been most unfortunately vitiated by the unwitting use of previously-infected combs.—A DEVONSHIRE BEE-KEEPER.]

MY DOGS.—No. 3.

MY DOG WHEN I WAS A LONG LAD.

In the *Saturday Review* there has been a series of papers on womankind, most of them unfair, one of them very offensive.

I allude to that entitled "The Girl of the Period." The writer of this production is, I imagine, what Dean Swift called "a nice person," which he said meant "a person of nasty ideas." But just as people who are habitually liars occasionally speak the truth by accident, so this "nice" or "nasty" writer, describing girls between the school and the young-lady age, calls them "nymphs," a very happy term—not children, nor yet romping schoolgirls, nor yet settled down into young-womanhood. But by what term can I describe the same age in the other sex? Youth pairs with maiden, and both imply—love. But there are yet a few years between childhood and youth before that pleasing troubler comes. "Hobbledehoy" is not a pleasant word; it seems to imply awkwardness and clownishness. We see before us an uncouth farmer's son, whiteslipped and hobnailed. Now suppose that, in want of a better term to describe this portion of human life in mankind, I call it the "long-lad" age. The long lad is no more a play-absorbed boy, but he is not ashamed of coming down to a good game occasionally. He is not so ready as before to make friends with everybody—

"To bear his heart upon his sleeve,"

but he delights in a chum. He is uncommonly shy before ladies, especially if he be a very long lad; but he is a capital brother to his sisters, and is ever ready to use his long strong arms in their service, to do for them what they have not strength or height enough to do for themselves. The long lad is getting out of the Egypt of dirty clothes and fingers, and untidy hair, and just near enough the Canaan of youthful beausism to rush to his room at the sight of strangers, and put on a new necktie, which he considers the very sum total of dressing. The long lad is frequently, nay, almost always, absorbed in some favourite game or pursuit. Rabbits he deems childish, so he goes in for Pigeons, and is learned in the length of a beak, or the number of feathers in a tail. Or if he is in the way of learning to shoot, and obtains by coaxing a gun, that becomes his delight, his charmer, his everything—it is to him what his horse is to an Arab. The long lad envies not the man with a license, who may only shoot here and there. He shoots everywhere. His game is Rabbits, Fieldfares, and Wood Pigeons. He will spend hours in pursuit of such, watching and waiting like a sentinel in the damp and cold. But the long lad usually delights also in a dog, which he will teach all manner of tricks, but a rat dog and a rabbit dog it must also be.

When I was a long lad I had a rat dog, a terrier, sandy in body, dark in muzzle and legs, therefore as to colour a black and tan reversed. He was bought because of his quickness at ratting. His name, of course—Pincher—not a refined name; but the long lad cares little for refinement, he goes in for fun and for sport. His name, as I said, was Pincher, and it is wrong to change a dog's name. He will take another, but not wholly, and is delighted beyond measure if any one calls him by his old name. I fancy a dog feels it to be a sort of insult or rudeness, as it certainly is for other people to call one's children by a different name to that by which they are called by their parents. If I always call a son Henry, I think it bad manners, as it is, if another person will insist on always calling him Harry.

Well, Pincher was bought and brought home in the evening to exhibit his rat love and prowess in our barn, then rat-troubled. I brought him home, and you will usually find it correct, that whoever brings a dog to a new home, that one of the new family he takes to. He seems to think, "I knew you first, and you were kind to me; you brought me into a scene amid new faces, I knew your's first. I turned to you as a friend; you were kind to me first, so I love you best. You brought me my first milk, or my first bone, and you took me to my kennel and fetched a bundle of clean straw, and carefully put a pan of water near me, and as you showed me love first of all, I'll give you my love in return."

Pincher's performance in the barn was most satisfactory; among rats he was in his element, and at the very highest pinnacle of his being's enjoyment. Not a hunter with bounds in full cry, not a sportsman when the brown-backed covey rises before him, has more intense joy—joy that thrills through his frame and looks out at his eyes, than has a terrier among rats. Notice his forward-thrusting, audibly-smelling nose, his attitude of perfect symmetry, his keenness, his eagerness, his sharp short bark, and his sharper whine—a noise only heard when rats are near, and, to sum up, if it be dark, his eyes shooting green fire.

The long lad and Pincher went to many a rat hunt, specially when a corn stack was being lowerel. The rats go lower as

tier after tier of sheaves is removed and put into the jaws of the threshing machine. At last every refuge fails, and the poor vermin are obliged to run, for the very last sheaves are being lifted. That is the time for a terrier to show his skill. Men brandish sticks, boys shout, and run after the running rats. A coward dog eries about his bitten nose, he having made one clumsy attempt at killing a rat and, ha! made up his little mind never to try again; while, on the contrary, the practised, business-like, bold terrier kills, and kills, and kills, losing not a moment of time. It is a nip and a toss, then another rat is nipped and tossed, and then another, faster than you can read this account. It is an exciting scene, and a good rat dog acts like a good surgeon, cleverly and quickly doing his work.

But if Pincher had his virtues he had his vices too, and they, alas! were the result of his intercourse with man. He was, I am ashamed to have to write it, a taught thief; but as he stole not for himself, but for his master, so

"E'en his failings leaned to virtue's side."

To our great surprise, Pincher one day brought home a pound of butter, and laid it, not in the least injured, for he had a very tender mouth, at our feet, looking up expecting to be "highly commended," for his eyes and ears and tail showed very evidently that he thought he had performed a very meritorious action. A mutton chop was brought another day, a piece of cheese another, and so on.

Poor dog! He had been trained by a dishonest master to steal, and so he stole for me. I watched his method of proceeding. He would stand on the top step of a butcher's shop door, one forefoot raised, and his eyes peering in. So long as the butcher was looking his way, he did no more than look in, but when butcher and customer had both turned their backs, then Pincher bolted in, and invariably chose a very nice piece of meat. Home then he came, as to eat the meat or even gnaw it, that never entered his thoughts; he was a disinterested thief. With more truth than Falstaff, poor Pincher might have said, "Convey the wise it call," for he simply conveyed eatables from one house to another. To return the thing stolen was not always possible, as Pincher did not always deal at one shop. Soon this thieving became a nuisance.irate fast-trotting butcher boys followed Pincher with cracking whips, but never caught him. The grocer's youngest apprentice appeared at our door in a highly excited mood demanding stolen butter or cheese, or once a blacking-brush. The dog was beaten, but he stole all the more, thinking that he had not stolen enough to please. It was not pleasant to ride past a shop with the dog at one's heels, and to hear, "Look out, there goes the thief," the words seemed to have a personal sound. At length, gradually, very gradually, Pincher was taught better. Somehow it was made to enter his head that not to steal at all was the right thing, and to steal was the wrong thing. Yet it was manifest that he loved the fun of the thing. Often would he stand and look into a shop, and then look at me, saying plainly in eye language, "Do let me, only this once, it is such capital fun." I am sure the excitement of the chase pleased him. The impotent-to-catch, but furious butcher, baker, or grocer, the consternation he caused, all this delighted the dog. "You can't catch me, you can't catch me," and away he went, knowing that he had four legs, and a good start, and his pursuers only two.

I said that Pincher by hard training became reformed. Reformatories did not exist then, or I might have sent him to one. Long time, like a reformed drunkard, did he hang round the various scenes of his former exploits, but fully reformed he at length became.

Pincher's exuberant spirits occasionally got him into some disgrace, as when rushing one day into my Pigeon loft (he was accustomed to go in with me), his rat mettle up, off flew a hen Barb, a new-comer, just hatching her first eggs; the dog seized her, and she was limp and dead in a moment. My displeasure was almost unbounded, as was Pincher's penitence. My only Barb hen, and not another nearer than London, and no other Pigeon to take to the eggs. But except for a scrape or two such as this, Pincher lived in favour, he was the companion of my long-lad days, and he helped to make them more agreeable, and, perhaps, even more innocent.—WILTSHIRE RECTOR.

OUR LETTER BOX.

FEEDING ONE HUNDRED FOWLS (*H. C.*).—We cannot advise anything better than what you already make use of—viz., barley and Indian corn, with a change of wetted meal, but we are no advocates for buckwheat. It

might, perhaps, be more economical to substitute offal wheat for barley, where it can be had for 3s. or 3s. 6d. a-bushel, and we should think a bushel of this ought to last more than a week, and if about 3s. or 4s. worth of a mixture of barleymeal and pollard were mixed with any waste potatoes, including the outer parings, boiled and mixed-up with the meal into a thick paste, we think the whole ought to be kept for, say, 8s. or 9s. per week. Of course, much depends on whether many of them are young or not, as young fowls require more feeding than old ones. If they are to be kept in condition fit for table, more food may be wanted, but in general old birds do not lay so well when overfed, and we like a fowl direct from the yard better for table than a coop-fatted one. We need hardly say that in mild open weather the fowls will pick up a good quantity of food from the ground.

MANAGEMENT OF FOWLS (*Cestria*).—Your inn, No. 1, will do perfectly for Game fowls, or Bantams, or Silkies. It would do for a small run of Cuckings, and these would be the most profitable. No. 2 will do well for Brahmars. We have Bantams running about our kitchen garden without doing any damage. If you keep the house clean, and supply the fowls in a dry basking place with road sand or wood ashes mixed with black sulphur, they will have no vermin. You should feed three times per day—at daybreak, midday, and evening. Good barley, ground oats, barley-mead are all good food. Indian corn is a change, and the table scraps are excellent helps. Sand is a bad bottom for a pen. Gravel is the best, road-grit is next, but sand is cold, damp, and sloppy.

FEEDING GOLDEN-SPANGLED HAMBURGS (*Far West*).—Peas are only used to harden plumage, and to give many of them is injurious feeding. Ground oats form the best food for fowls, varied with Indian corn in small quantities, and with stale crusts and crumbs steeped in milk, or in cold weather in strong beer. Wheat is not good food.

DUCKS' EGGS DARK-COLOURED (*Capt. Horne*).—It is a sign that the Ducks are not in condition, but does not interfere with the wholesomeness of the egg, nor with its food properties. It is probable, if the Ducks were shut up in an old pigsty for a week, and fed only on meal, oats, gravel, and grass, that the colour would alter. It is worth trying with two or three, as, if the experiment were a success, it would prove that the objectionable colour arose from something eaten by the Ducks, and that interfered with their secretions. These vagaries are sometimes caused by fat.

EMBLEM GOSSINGS (*A. H.*).—The weight will depend on the age. We have Tealouse Goslings in ordinary running condition weighing 14 lbs. each. We doubt whether you can obtain Embden Geese. Try at Mr. Badly's, Mount Street, Grosvenor Square.

SEX OF PEA FOWLS (*J. W.*).—The sex of Pea fowls can be easily discerned when they are twelve or fourteen weeks old. Barley is all the food they require when they are half-grown, but up to that time they want feeding like young Turkeys or Pheasants. They are delicious eating when about eight or nine months old. Their value under twelve months old is about 8s. each. After that, they vary. When the feathers were the fashion for ladies' hats, a Peacock in colour was worth 30s. The fashion is altered, and he is now worth about 12s. or 14s.

GAME COCK'S BEAK BROKEN.—"I have seen, where a cockerel was fighting with another through his crib, the bony substance broken off his upper mandible and leaving a fleshy substance nearly the length of the under one, but it was replaced by a fresh one in a few months.—H. G."

PIGEONS DISEASED (*A. S.*).—It is best always in sickness, whether of man, beast, or bird, to look at the cause more than the symptoms. Thus, if a child has a sore mouth, the cause is a bad state of the stomach, cure that and the mouth will become well. We infer from the state of your Pigeons, that your loft is either cold, damp, or draughty. Fancy Pigeons cannot well be kept too warm; they always do best in a celled room. As you have tried the old remedies, and found them fail, adopt those recommended by "A FOREIGNER," a very skilled fancier, in our Journal of July 30th. He says, "Some Pigeons are recovered by one remedy, some by another, and others never; some get rid of roup by a dose or two of charcoal powder, some by a dose of carbonate of soda, or a pinch of alum, and some by a dose of flowers of sulphur." In regard to your Carrierhen not getting her feathers after moulting, this shows also want of warmth—feed her on hempseed, and put her in a warmer place. Put a number of clean screws into your Pigeons' water, we prefer them to nails; but of all things, set to work and make your loft warm. Damp, cold, and especially currents of wind are ruinous to Fancy Pigeons. The excrement left on boards causes a loft to be damp.

STUFFING BIRDS (*Self-taught*).—We know of no liquid that can be applied to birds rendering the skinning unnecessary. In our No. 380, you will find our suggestion about drying moss. We have no further information.

FEED OF A COW IN WINTER (*H. C.*).—If your Alderney cow has the privilege of being turned out on the three-acre field you mention, which she ought to have to do well, and is allowed to pick up a little straw with which she may be supplied as litter, we should think she ought to do well on from 4 to 6 lbs. of cake per day, and about 2 tons of hay for the winter; but so much depends on the amount of extra food she may pick up that the quantity of hay cannot be strictly laid down. In feeding it is advisable to give only a little food at a time and often, and not to allow her to waste much. Some food she will very likely refuse to eat, but let that be as small a quantity as possible. Cotton and other cakes improve the quality rather than increase the quantity of the milk. Sort foods, as brewers' grains, mashies, &c., increase the quantity, but it is poor in proportion to the extent it is so forced. We would by all means turn her out a few hours every day; even if there be nothing to eat, the exercise will be beneficial. We are sorry for the delay in answering your inquiries; it arose from causes not easily prevented.

COOKING CONVE TRENCHES (*E. D.*).—The midrib of the leaf is the only part used; it is not to be peeled, but must be quite free from the green part of the leaf. For cooking it, tie the kale in small bundles, and cut off the ends to make them all of the same length; have ready a pun containing one gallon of boiling water, and 2 ozs. of salt. Roll the kale rather quickly for half an hour or till tender, dish it up with a piece of toast under. Serve very hot with some good melted butter. The Conve Trenches dressed as above is an excellent vegetable; but it is never tender till after it has been exposed to the frost. It is not, as generally supposed, a delicate plant, but quite hardy, and can be used all through the winter.—(*From a Correspondent*).

WEEKLY CALENDAR.

Day of Month	Day of Week.	NOVEMBER 19—25, 1868.	Average Temperature near London.			Rain in last 41 years.	Sun Rises.	Sun Sets.	Moon Rises.	Moon Sets.	Moon's Age.	Clear after Sun.	Day of Year	
			Day.	Night.	Mean.	Days.	m.	h.	m.	h.		Days.	m.	h.

25	W		47.5	32.5	40.0	21	37	7	57	3	21	2	49	1

From observations taken near London during the last forty-one years, the average day temperature of the week is 48.3°; and its night temperature 34.2°. The greatest heat was 61°, on the 20th, 1863; and the lowest cold 9°, on the 23rd, 1858. The greatest fall of rain was 0.95 inch.

MARKET GARDENING ABOUT LONDON AND PARIS.—No. 2.

WITH regard to the vast superiority of the French market gardeners in the production of various kinds of vegetables and fruits much has been written, and, at the same time, the habits of the French themselves have been extolled as so much better than our own: on looking at the whole subject, I am inclined to think that after all it is a matter of demand and supply, and that the habits are simply those which difference of climate to a great extent brings about. We are told how far ahead they are of us in the production of winter salads and Asparagus. Pears and Peaches, while contrasts are drawn between our more meaty banquets and their larger supply of vegetables and fruits. Now, the character of a nation's food depends to a great extent on the character of the climate. The Esquimaux of the Arctic circle knows nothing of vegetable food, and were the finest productions of French and English gardens to be placed before him he would prefer his lump of whale's blubber or seal's fat, and to him the greatest treat is the reeking carcase of some fresh-killed walrus. And why is this? We may turn away with disgust from the very idea of it, but he has learned in that cold and bleak climate by experience, what science teaches us—that nothing so tends to generate the caloric he needs, and the white man, who, like poor Dr. Kane, has the misfortune to be shut up in those dreary regions, soon learns that he, too, must abandon his more civilised food, and “do at Rome as Rome does.”

Our own climate, although in winter not so cold, perhaps, as Paris in the actual lowness of temperature, has yet that which makes it far more trying in the constant damps and fogs to which we are surrendered; the air of Paris, especially, being dry and thin. I am assured by a friend, whose name is honoured wherever gardening is known, that, from a record of temperature he kept for many years, there is very little difference in the degrees of cold in London and Paris up to the end of April; and yet the Frenchman, who is doomed to spend a winter in London, looks forward to it with feelings of dread, as if he were about to be consigned to Dante's “Purgatorio;” it is the terrible *brouillard* which frightens him, and so terrible does he think it, that nine out of ten Frenchmen believe nearly all London is on the verge of suicide in the early part of winter. Now, this does to a great extent regulate our habits of eating and drinking. Notwithstanding that you may now get claret as cheap nearly in London as in Paris, how few there are who will drink it in the winter months. “Nasty cold stuff,” says lusty John Bull, who prefers his foaming tankard of ale or his fruity port; albeit dread “podagra” lurks within the cup. As to salads, oh! the very thought sends a shudder through him: he may condescend to take a bit of Celery with his cheese, for it is warm and aromatic, but I have often noticed at tables where the salad was a constant adjunct, that not one-half of the guests partook of it, and I believe that dread of all sorts of “internal

commotions,” and not taste, leads to the refusal of it. And so with fruits, most people think after the beginning of October Pears are over, and at a dessert dried fruits are almost always preferred. Now, cross the Channel, and things are different: the almost universal beverage winter and summer is the thin *vin ordinaire*, while no Frenchman high or low would consider his *menu* complete without a salad, but without that he is a considerable eater of flesh. What with his *cotelettes*, *roti*, *ragouts*, &c. twice a-day, he does pretty well.

Go further south. The Spaniard with his Water Melon and his *olla podrida*, or the Neapolitan with his macaroni, would consider the Frenchman decidedly carnivorous; his warm climate does not necessitate the heating food of the more northern nations, indeed, it would be positively injurious to him; while in the tropical climes of India and Africa animal food almost ceases to be an article of diet, and Rice, the very thinnest of all the cereals, is sufficient for his wants. Now, it would be very absurd for the Hindoo to laugh at the Frenchman, and speak of his animal tastes, and equally absurd I think it is to hold up the more refined tastes of the Frenchman, because he is a greater vegetable eater than the Englishman.

Now, all this must considerably affect the supply of food. Although a vast improvement has taken place in the quality of meat in the Paris market, yet in vain will you look for the wonderful triumphs of the feeder's skill that everywhere meet you in London; but go into the vegetable markets, and you are at once struck with the difference. We have, it is true, no place save dear, dirty, dingy Covent Garden to display our productions; we lack the truly magnificent Halles Centrales, but with all that you see at once the difference. In Paris salads of various kinds abound in winter—*Chicoree*, which, remember, is Endive, of wonderful size and whiteness; *harbe de capucin*, which is really the blanched shoots of Chicory; Lettuce, both of the Cabbage kind and Cos, or *salade Romaine*, as it is called there, are brought to perfection. But, then, you never see a head of Celery worth looking at, nor in summer a Cucumber that would be tolerated in any English garden, save at such shops as Potel & Chabot's in the Boulevards, or Chevet's in the Palais Royal, and these are evidently imported; the French care little for either one or the other. A *salade de Celeri* is about as uninviting a production as you can well imagine, and as they have not yet learned the value of a Cucumber with salmon or fish in general, it is needless for. Shall I, then, because the market gardeners of Brentford and Fulham can produce Celery which might well serve for a marshal's baton, or Cucumbers to be measured by the foot, say that all this evidences the vast superiority of English market gardening? No; I say it is simply cause and effect, demand and supply. I know it may be said, “But do we not import large quantities of salad in winter from Paris, and does not that prove that it is in demand, and would pay to grow?” I do not quite see this. Many families have learned to value winter salads, but the great mass of the people do not, and it would no more pay, I believe, for London market gardeners to force salading than it would their Parisian brethren to grow Cucumbers.

A market gardener has to consider the wants of the many, and not the tastes of the few; he requires a sure and not a precarious demand. I have seen baskets of French salad in Covent Garden consigned to the outer circle, although they have been imported by the first-rate merchants of the Central Arcade, showing that there is no such overwhelming demand for them. Again, in the matter of Asparagus, of which more must be said by-and-by, it is decidedly more eaten in France than in England; during the season it is in general demand, and this not so much because of its greater cheapness as of a matter of taste. It might then, perhaps, be of advantage to English market gardeners to grow it more extensively, but there are other crops which are more sure of finding a market than it. Can there be any doubt as to the possibility of the Cornish growers, who so regularly supply the London markets with early Potatoes and Cauliflowers, being equally able and ready to send up any quantity of Asparagus, if it paid them to go in for it?

I do not think that in the mass French folks care so much for the quality of the fruit they eat as for the quantity. With them size is a most attractive feature, and a large Duchesse d'Angoulême Pear, gritty and coarse-grained, from its great size, even finds favour. What can be more insipid than the Abricots de Midi and Pêches de Midi which find their way into the Paris markets? and yet how eagerly they are eaten! Even the far-famed Peaches of Montreuil are to my mind very sattring, owing, probably, to the quality of the soil, and by no means to be compared with those which are grown in some of our most favoured localities.

The Parisian market gardener is in some respects like, but in others very different from, his English confrère—both have the same facilities for procuring large supplies of manure, without which, indeed, in neither place could the crops be obtained; like him, too, he is being jostled out of his holdings by the extension of the city on all sides; but I believe he enjoys a greater advantage in the cheaper rate of wages. Much has been said pro and con, on the matter. I can only say that I entered into this question with some of the men themselves. The very intelligent foreman at —'s, at Clichy, told me that, including everything, his *étrennes* at the New Year, &c., the whole sum that he obtained in the year was 800 francs. Compare this with the foreman of a London market gardener, and I think the advantage will be seen. The men themselves earn about 15 francs a-week; and then most of these market gardeners are very small holders, they work themselves like their own men, and in a holding of a couple of hectares (between 4 and 5 acres), it is not usual to find more than two men in constant employment, besides the owner, and probably his son: hence they can more cheaply send in their supplies. And these men work hard; the foreman alluded to above told me that in summer he worked for eighteen hours, and that without any additional "over-hours" pay. All this gives a considerable advantage to the French market gardener; and yet I very much question with all this, whether there is that superiority in him that some have seen, and whether the method of culture in and about London does not pay quite as well there as the French system in Paris; and this is, after all, the great question. No mere dilettanti notions of what is pretty or neat must enter into the question, it will be simply what pays best.

These facts, for such I believe them to be, will explain much that has been said on the subject, and it is essential, I think, to the proper understanding of it that they should be borne in mind, for we can thus without prejudice look at the whole subject, and derive, it may be, both instruction and amusement from it.—D., Deal.

A LARGE FRUIT GARDEN.

SOME time early in October last I had the great pleasure of visiting Mr. Varden, of Seaford Grange, to look over his young plantation of fruit trees, quite enormous in extent. The entire estate consists of 250 acres, with a charming, well-built, and ornamental dwelling-house in or about the centre. One hundred and twenty acres of the estate are formed into a fruit garden, intended to supply the wants of the "black country"—i.e., the coal and iron districts to the north of Pershore. The plantation was finished in the year 1858. The soil was drained and prepared as described below. This garden contains from 40 to 50,000 Gooseberry bushes, and from 90 to 100,000 Currants, mostly Red, only some few thousands being the Black Currant.

The fruit trees, arranged in rows from 15 to 18 feet apart, row from row, and about 12 feet apart in the rows, were for

the most part planted as dwarfs, maiden and two-years-old. They have now grown into trees with heads and several stems, the lower branches having been pruned away.

The following is a rough approach to the number of trees planted in this very interesting fruit garden:—1500 Victoria Plums, 1100 Pershore Plums, 700 Early Rivers, 500 Diamond, 600 Gisborne's, 500 Jefferson (soil and climate too cool for this sort), 150 Reine Claude de Bavay, 120 Autumn Compôte, 50 Damascene (a large sort of Damson).

The varieties that have proved themselves adapted to the cool soil and climate, and are likely to be a source of profit, are Victoria, Autumn Compôte, Early Rivers or Early Prolific, Gisborne's, and Pershore; the Diamond is not quite hardy enough. Mr. Varden has under trial some promising seedlings, raised by me some few years since.

There are several other varieties of Plums cultivated here to a small extent, but at present few seem hardy enough to bear and ripen well. I saw some fine rows of trees in the most vigorous growth of Sandell's Plum, but the fruit had been a very, very thin crop, the climate being too cool or the soil too rich for it.

The plantations of Pear trees are for the most part remarkably healthy, as far as regards freedom from canker, moss, and other plagues peculiar to the fruit garden. First of all I visited a plantation of some thousands of Pears on Quince stocks, in which I have always felt a lively interest. It consists of several thousands of Louise Bonne, Beurré d'Amanlis, Vicar of Winkfield, and some others, all in good health, and capable of bearing large crops; but although they put forth annually abundance of blossoms, they but rarely bear good fruit. For some years after the severe frost of 1860 they seemed to have been paralysed, and were quite barren. They now appear vigorous and healthy, the soil seeming to be admirably adapted for them, but they do not bear to any extent—not enough to pay for their culture. I have never before witnessed so vividly the effect of climate on Pear culture as with these trees, the large extent of a cool soil and flat surface evidently lowering the temperature from 1½° to 2°, thus making the climate a trifling degree too cool. It is evidently not the geographical position of the place, but purely the locality, for in the gardens of Pershore, about three miles to the south of Seaford Grange, and on the banks of the Avon, where the soil is light and warm, the choicest kinds of Pears ripen well on pyramids in the open air. It would seem that in open-air culture the soil makes the climate.

The principal kinds and number of Pear trees grown as standards on Pear stocks are the four hundred Doyenné d'Été (Summer Doyenné), and large numbers of such kinds as Marie Louise, Knight's Monarch, &c. I was much interested with these trees, the first named in particular, for there were rows of standards, some 20 feet high, forming avenues, every shoot glistening with health, and studded thickly with blossom buds. Knowing well the tendency of this sort to bear with me so freely as to break down its branches with the weight of fruit, I at once inquired as to the crop of the past summer, gathered, as I supposed, in August. The reply was, as far as I recollect, they bore but very few, and have never borne any worth sending to market. Here was another Pear lesson, reminding me of the old fable, which is one of my boyish recollections, and runs as follows:—Two goldfinches, warmed by some fine weather in February, built their nest and had their young progeny; then came March with frost and snow, which killed their young and nearly starved the parent birds. This is, I think, told in verse, and the moral is—

"Mises, the tale that I relate,
This lesson seems to carry—
Choose not alone a proper mate,
But proper time to marry."

This may be easily paraphrased: Choose not alone the proper soil, but proper place, in which to plant Pear trees.

I observed when looking closely into the habits of the Marie Louise and Monarch Pear trees a clear shining bark and healthy buds, but a seeming want of vital force in their structure, arising from a temperature too low and moist in summer. Beurré de Capiaumont, Williams's Een Châien, Achan, and some others, grow with a robust habit, bear fair crops, and give good promise. Mr. Varden has, like all extensive fruit-tree planters, had to pay a high price for the experience he has

* Some hundreds of acres are occupied with this Plum—a variety of the White Magnum Bonum (its name in the district, of the same colour, but about half its size. Thousands of bushels are dispatched weekly from Pershore in September to the north, and in a green state in summer for drying.

gained, and is gaining annually; but in a climate so variable as that of England it must be so. Those who advise people to plant Pear trees in waste places are sorry advisers.

The Apple trees in the Seaford garden are all very healthy. There are rows and acres of the popular sorts—six hundred Sturmer Pippin, four hundred Duchess of Oldenburg, five hundred Damelow's Seedling, and many hundreds of trees of other popular sorts, all free from canker and full of blossom buds. They have not, however, as yet borne freely, owing to the ravages of the grubs of the Winter Moth, which in spring has denuded the trees of blossoms and leaves, thus weakening their system. This pest seems peculiar to Worcestershire, as I have never heard of its ravages in our southern fruit gardens. There is no doubt but that this fine and well-planted fruit garden will in the course of a few years become of great value, for Mr. Varden is re-grafting all his trees that do not suit the climate, with varieties that he has found to do so. The following accurate description of the garden has been drawn up by a resident at Seaford Grange; it seems to me interesting and worthy of publication.—THOMAS RIVERS.

THE FRUIT GARDENS AT SEAFORD GRANGE.

NEAR Pershore (Worcestershire), is one of the largest fruit gardens in the kingdom. It was commenced fifteen or sixteen years since on a comparatively small scale by the owner of the land, Mr. Varden, to afford him occasional relaxation from the duties of civil engineering, which were pressing too much on his health. He afterwards retired from his profession, and has since entirely occupied himself with farming and fruit culture. The garden has gradually been increased to 120 acres; and as in that neighbourhood land is cheap (30s. per acre), and manure dear (10s. per ton), the high cultivation adopted near London and the large towns is not attempted, but something between it and ordinary orchard culture is practised, and with intermediate results both as regards cost of cultivation and value of produce.

The leading idea was, that if fruit were grown without vegetables the rich, deep, high-priced lands which are practically necessary for the latter might be dispensed with; heavy loams at 20s. or 25s. per acre being really better adapted for the growth of Apples, Pears, and Plums than the light soils at from £3 to £5 per acre generally selected for market gardens.

The soil before being broken up was 1 foot of brown loam and 2 feet of yellow loam resting on blue clay. The loams contained 75 per cent. of silicates, 10 per cent. of alumina and peroxide of iron, and 2 per cent. of carbonate of lime. The blue clay contained 37 per cent. of carbonate of lime, and only 6 of alumina and peroxide of iron, so its mixture with the loams would be beneficial; but as it occurred at too great a depth to be brought up by ordinary double-digging, this only occurred to a small extent. When converted by deep thorough draining from a substance like soap into a friable mail it becomes well adapted for the deep roots of large fruit trees, and is by no means an unfavourable subsoil. An analysis of the water which escapes from the drains (2 feet deep), shows that in each gallon there are present 21 grains of sulphate of lime, 10 of carbonate of lime and soda, 6 of common salt, 4 of sulphate of magnesia, and 15 of organic matter.

The soil is one of the middle beds of the lower lias, with little or no alluvial deposit on the surface, and in its unimproved state in 1851 was worth about 10s. or 15s. per acre. Now that it is cleaned, thorough-drained, and useless hedges are removed, and the panic produced by the repeal of the corn laws has subsided, it is worth about 80s. per acre. It slopes towards the east from a brook 40 feet above the level of the sea, to the summit of a hill 114 feet above the sea level. But the gardens do not extend into the lowest ground; they commence at 15 feet above the level of the brook. None of the lucky orchards of the neighbourhood are less than 30 or 40 feet above the bottom of the valley.

From the above sketch it is to be expected that the defects of this site for fruit-growing will be more in climate, resulting from lowness, than in soil. The latter is evidently well suited, even in its unimproved state, to large hardy sorts of Apple and Pear trees; and in the gardens (all of which have been deep-drained and double-dug), Walnut trees and some of the standard Pear and Plum trees have in fifteen or sixteen years attained the height of 20 or 25 feet with every appearance of robust health. A moderate application of manure will supply its deficiencies, and adapt it to the growth of the less vigorous sorts and of the Gooseberry and Currant bushes, which con-

stitute the undergrowth. At first stable manure from the towns was employed for this purpose, but latterly soot has been substituted, the effect of which on lias soils is remarkably good.

Hard frosts are very injurious to the lower portions of the plantation up to the level of 30 or 40 feet above the brook, and it is to mitigate or counteract the effect of these that attention should chiefly be directed. Mr. Varden has latterly diminished the number of his trees per acre, partly with the view of allowing them as standards to attain their full height and grow above the level of the most destructive frosts, and partly to lessen the labour of darning round the stems every third or fourth day in November and December, to check a particular blight—the caterpillar of the Winter Moth, which has infested the Worcestershire fruit districts, especially those round Pershore and Evesham, for the last twelve years. He appears satisfied with the result of this, and experience shows him that there are sorts of fruit which suit his soil and mode of cultivation, and fairly resist the frosts even of his lower ground, and the number of these sorts being small is no disadvantage. The likes and dislikes of the different varieties may be humoured in private gardens where the object is to produce fruit irrespective of profit, but in commercial gardens profit is indispensable. Not only must the peculiarities of soil and climate be more closely studied in the latter, that the produce may be raised at small cost, but peculiarities of markets and means of transit be allowed due weight. For instance, the highest class of fruits, requiring both good climate and abundant manure, are best raised in the metropolitan district, where those united advantages are attainable at smallest cost, and where London, the chief market for such fruit, is within carting distance, so that the damage caused by shifting from road to rail and from rail to road is avoided, and the fruit taken in a ripe instead of an immature state, as is necessary when it goes by railway. Gardens in the midland counties are almost excluded from this branch of fruit-growing; and the cheap rate at which Apples and moderately good summer and autumn Pears are produced in the farm orchards which extend over large portions of the counties of Worcester, Hereford, Gloucester, Somerset, and Devon partially excludes them from growing those descriptions of crop also. The province of commercial fruit gardens in the midland counties seems to be the production of a class of fruit between these two—i. e. the very good, and the very cheap; and even this has to be accomplished subject to apparently capricious arrangements of railway charges, the inequalities of which cannot be foreseen nor controlled. Thus, from the neighbourhood in question the Great Western Railway can convey fruit northward to Liverpool and Manchester, and southward to London. The former is the longer distance, yet the charge for Plums, Gooseberries, and Currants is only 60 or 65 per cent. of what it is to London. The whole of those fruits which are sent out of the district go northwards, hence for the present the proprietors of Worcestershire fruit gardens have only to consult the wants and tastes of the northern populations; but whether the opening of the new Midland line into London may, by competition, lower the rates southward and allow an entrance into the London markets, remains to be seen; but even if it should, only such fruits as can bear the rough usage consequent on changing from road to rail and back again will suit the trade.

The limitation of varieties which must result from the combined effects of natural and commercial causes can in no case be exactly foreseen. Experience is always necessary to determine it, and this Mr. Varden has now had. The numerous sorts of Apples, Pears, and Plums with which he commenced his plantation (some only experimentally) are being reduced to very few, the names of which I need not particularise, but will rather allude to those which have been discarded.

Among Pears usually considered hardy as standards, the Summer Franc R6al, Knight's Monarch, Aston Town, Louise Bonne of Jersey, and Bishop's Thumb are all deficient in vigour. The cause of this is no general unsuitableness of soil to the growth of Pears, as the Crawford, Grey Baur6, Welbeck Bergamot, and Winter Crasane are in robust health and bear well; it rather points to the former varieties requiring more heat or nourishment. Other sorts, such as March Bergamot, Tigne de Naples, No Plas Meuris, Doyenn6 d'Amour, Shobden Court, and Citron des Canines grow well and bear moderately, but not sufficiently for profit. Similar results attend Apples. The Gooseberry Pippin, Court-Pend6-Plat, Gloria Mandi, all do badly, and Sturmer Pippin doubtfully; while Duchess of Oldenburg, Damelow's Seedling, New Hawthorn-

den, Fearn's Pippin, and Scarlet Crofton do well, and similar diversity is exhibited by Plums.

When the weeding-out of unsuitable sorts is complete, and such minor improvements of cultivation as will result from experience are introduced, a considerable amount of success may be expected to attend these gardens. The above remarks show how necessary it is that the great difference between private gardens and commercial gardens (general excellence in the one case, special excellence in the other), should be steadily pursued. The orchard districts of the western and mid-western counties afford soils and climates of great value for fruit-growing, and may if judiciously utilised supply the larger towns, especially of Scotland and the north of England, with abundance of good and cheap second-class fruit, such as is in ordinary demand for family consumption, without materially affecting the metropolitan districts, whose advantages of climate, manure, and situation fit them for producing the superior sorts.

I am inclined to think the Apple, Pear, and Plum trees in Mr. Varden's gardens would more effectually resist spring frosts if the ground round their stems were kept free from shade and undergrowth to a greater distance, the soil to that extent left undisturbed further than by hoeing and weeding, and a dressing of manure, somewhat larger than the present, applied wholly on the surface. This would encourage the roots to grow nearer the surface, where the temperature would be higher and the moisture less than lower down, and the result would be a smaller growth of better-ripened wood.

CALCEOLARIA DISEASE.

AFTER so frequently hearing of Calceolaria failures during the past summer, it is pleasing to read of the success of "M. H.," detailed at page 312; and as I quite agree with your correspondent as to the importance of deep culture and a cool subsoil, a few notes which I have to offer concerning the disease and its causes may not be out of place. It may be well, perhaps, to state that with me Calceolarias have flourished this season; the only marked effects produced by the drought and heat were a shorter period of blooming than is usual, and, consequently, an earlier and stronger autumn growth.

In examining diseased plants I have observed that the bark has invariably been either quite dead or else very much decayed at the collar of the plant, and thus, an obstruction having taken place between the roots and foliage so as to prevent the rising of the sap, disease and death quickly followed. Now, if it be granted that the collar of the plant is the actual seat of the disease, I would then inquire what is the cause of this, and why should the signs of decay first occur at this particular place, rather than at the roots, or in the branches? Is it that some slight injury or bruise has been inflicted on the delicate bark of the plant in some of the earlier stages of growth, and that it has gradually spread till it has formed a ring of decayed bark and thus brought about the fatal result? Or is it that in some soils certain salts or acids are contained, which, when exhibited in a sufficient quantity, act so strongly upon the bark as to dry up its tissues? That this is likely to be the case I am inclined to think, because no signs of disease are perceptible in either the winter or spring months, but it is after the soil has been for some time subjected to the action of the burning rays of the summer sun, just, in fact, as the plants have become established in their summer quarters, and are putting forth their blossoms, that the canker makes its appearance, and from this I infer that the moisture of the soil which has hitherto exercised a restraining influence, being now absorbed by the sun's rays, the poisonous qualities of the soil are set free, and their deadly action but too soon becomes apparent. Or, it may be that the evil is occasioned by a deficiency of some constituent in the soil. Whether in either of these theories is to be found the true cause of the Calceolaria disease I will not presume to say, and in advancing them I by no means intend to infer that I have arrived at the actual cause, but it is rather in the hope that others may be induced to offer their experience on this subject, and that sufficient light may be thrown on it, in order that some definite conclusion may be arrived at.

The small number of good yellow-flowered bedding plants adds to the importance of this subject, and should varieties in any class be much increased, I am inclined to doubt if a fitting substitute will ever be found for those charming plants—Calceolarias. Yellow-foliated plants are very useful and effective, but they are not to be compared to Calceolaria Aurca floribunda,

possessing as it does a soft and lovely freshness of appearance which is the peculiar property of blossom, and to which foliage never approaches.

To return to the question of disease. I have generally observed that it most affects plants which have received some severe check in their early stages, or those which, having been propagated late in spring, are forced into a quick growth to render them large enough by the time they are wanted for planting out. Another evil is planting in a poor shallow soil. I met with an instance of this during the past summer in a garden the soil of which was not more than 15 inches in depth, resting on a substratum of chalk. In this case nearly the whole of the Calceolarias had succumbed, while with me in some beds not having a greater depth of soil, but with a cool clayey subsoil, the plants were all that could be wished, quite equal in health and vigour to some others growing in a much deeper soil.

It may, perhaps, be useful if I conclude this paper with a short summary of the mode of culture which is best calculated, if not entirely to overcome the disease, at all events to check it.

Let a sufficient number of strong cuttings be firmly inserted in a rich, sandy soil in a cold frame or pit in the first week in October. Let them be well watered, and slightly shaded when first put in, and watered as often afterwards as signs of flagging are perceptible. Let no air be given till the cuttings have rooted, and but little water will be required. On examining about two thousand cuttings to-day (November 11th) which have been so treated, I found the greater part had made roots, and all were looking well; not one showed the least signs of failing. Protect them from frost with dry litter, giving air on all suitable occasions, and let the plants be removed to more roomy quarters early in March, still taking care to afford them a rich soil, so as to promote vigorous growth; and let them eventually be planted out in the flower beds with good balls of earth at their roots, and in a rich cool soil, which has been deeply stirred, and I venture to assert that but little, if any, disease will occur, and it is very rarely that plants so treated suffer at all from green aphids.

I quite agree with "M. H.," in assigning the leading place amongst yellow-flowered varieties to Aurca floribunda, and to Victor Emmanuel amongst crimson. Another most excellent variety, though, perhaps, not quite so decided in its colour as the preceding kinds, is Prince of Orange, an entire bed of which offers to the eye a mass of rich orange brown as beautiful as it is uncommon. It is to be regretted that Canariensis is so weak and sickly in its growth, for its large flowers of a softer shade of yellow than Aurca floribunda, and its dwarf, compact growth, render it a desirable variety.—EDWARD LUCKHURST, Egerton House Gardens, Kent.

GOOD MELONS AND CUCUMBERS.

I AM not placed in the same predicament as your correspondent, "W. H. C.," in regard to Melons, but equally so in regard to Cucumbers, for I ordered some of the finest exhibition varieties of a very old-established firm, and received some of the most remarkable productions any person would wish to see; for they were short and long, and varied from a dirty yellow and dark green, but all seemed to be excellent seeders, as I could have obtained any quantity of seed from them. Not thinking them worthy I discarded the lot, and began afresh with my old favourite, Telegraph, which I have never found to fail in producing good Cucumbers, but it must be struck from cuttings, as it is seldom that one can obtain any seed from the true variety.

In regard to Melons I am something like your correspondent. I had Malvern Hall Melon, but whether true or not I cannot say, because I have not seen any one but my own, and that was somewhat as "W. H. C." has described it; in fact, not worth growing.

This year I have been much more fortunate in my selection of new Melons, having obtained Sultan, I believe one of the finest varieties for flavour grown, a freer setter, and attaining the weight of from 3½ to 4 lbs. It is also not liable to crack as some thin-skinned Melons are. The only fault I found in this most excellent Melon was, that after it had been cut for three or four days it began to lose its flavour.

Another new Melon which I would recommend is Dr. Hogg, which, although not so rich in flavour as Sultan, is yet a fine Melon, a free setter, and strong grower. It is about three weeks later than Sultan when both are planted together. The great merit of this variety, however, is its keeping qualities; I

have had it cut for three weeks and then sent it to table in good condition by placing it in the Pine stove for a night and a day previously.—JAMES STEWART, *Nunham Park*.

THE SUMMER PEACHES OF 1898.

In unheated orchard houses earliness of crop must ever be a test, and if this early production be in good number, nothing more can be desired, except, of course, beauty and flavour. That all these excellent qualities do not invariably unite under the same roof is, I fear, but too common. Commercially speaking—and let it be remembered that is an important side of the orchard-house question—there is no comparison between the value of an early Peach and of a late one. As yet, owing to some cause, but, no doubt, mainly to the great profits made by the fruit agents and dealers, orchard houses as a mere commercial speculation have not been so remunerative in their results as might have been wished. In certain specified cases they may have been profitable, and in a year like the present one they, no doubt, have done well; but, as a general rule, the testimony of those who have fairly tried them is, that they do not "pay" so well as vinerys. The reasons are, as I stated, chiefly owing to a combination against which the producer is practically powerless, but which may be remedied in time, and also that Peaches, being a most perishable crop, require to be gathered very carefully and sent to market exactly at times which suit both the state of the fruit and the demand for it. In these matters the Grape crop is certainly much more to be relied on, for it bears carriage far more easily, and it can hang until required. I have had a fair experience in these matters, and think that when we have still earlier sorts, and of good quality, orchard houses may become fairly remunerative. Such sorts, for instance, as some of Mr. Rivers's new seedlings, I look to as by far the most profitable in a monetary point of view. When, for instance, a Peach of good medium size (we can hardly look for more), having a good colour, fairly prolific, and not too tender, can be ripened early in July in unheated structures, it will always command a good price. For myself, I am working to obtain such by the end of June, and, if in good number, make no doubt of their success. At present we send Peaches from about the second week in July to Covent Garden. The whole crop under glass here this season was about two thousand, of which eleven hundred were disposed of, leaving an abundance for use and gifts.

It will interest some readers of this Journal who have written to me to inquire respecting this very matter (which has also been mentioned in these pages), and our numerous visitors who saw the crop on the trees, and can judge of its quality, to say here that we cleared 10 per cent. on the original outlay. Were deductions made for labour it is to be feared that even this sum would not be an inducement for speculators, considering the favourable season. Possibly it would be out of place in these pages to enter further into these details for obvious reasons, but I have no objection to join a private crusade against any unfair monopoly, which might thus be upset. I also think that the reports of certain fabulous productions have injured the orchard house cause very much; undue expectations, which exporters to the London market—no mean test, let me say—know cannot be realised for a continuance of seasons, are thus raised, to the damage of an excellent and popular system.

We have had this season many visitors, and of a class showing a larger acquaintance with the subject than in preceding years. Most of these visitors, too, were persons having large and expensive houses, amply stocked from the leading nurseries. From their remarks, and reports on the state of orchard houses in their neighbourhood, data of a conclusive character could be obtained. I have also aided and counselled proprietors by the score in the disposition and arrangement of magnificent houses, as well as those of very unpretentious size, and know pretty well what are the opinions current.

Of late I am becoming convinced that the public taste has much improved in all that relates to the qualities of Peaches. The proof of this is that now we may send in the yellow-fleshed Peaches (we always could the corresponding Nectarines), and that I see Mr. Douglas took a good prize at the Crystal Palace for Exquisite, a grand Georgian, which Mr. Rivers sent me some eight years ago. By chance it first fruited in our houses (in all Europe), and has been pronounced by Dr. Hogg as one of the very finest of Peaches. I am glad, therefore, to see my own ideas about this gorgeous Peach realised by these excellent

tests. It is a show and table fruit; not very prolific. But eight years ago, who would have been enthusiastic about a yellow-fleshed summer Peach? Now Crawford's Early is much admired, and I think is the most valuable for the market of second-early yellow sorts. It has also a fine piquant juice, and carries a high colour for the table; but, as it is well known, no more need be said. If, besides this and Exquisite, the lover of yellow Peaches select the Comet, he will have three fine and excellent varieties for show, as well as the table and market. Let me here say that what is saleable at a good price in these fruits is also, as a rule, generally the best to cultivate for private consumption.

I have tried nearly every Peach and Nectarine of any reputation, but they are far from being all equally valuable, for us at least. What is deservedly thought first-rate in other soils and climates is not always so here. Crawford's Late Peach, for example, I see in the official American Report is considered as having "no rival" in its season, but here it is bitter, and a shy bearer also. No shy bearer should be selected, because this inherent quality can never be changed, as far as I see now, and it is too apt to augment with age. Walburton Admirable and Teissier I would never have whilst others could be had. Nor again should otherwise good sorts like the Murrey Nectarine, be chosen when the stones occupy such a disproportionate space in the fruit. Many yellow-fleshed Peaches are bitter. Clingstones are not yet admired much; but this year we tried them sliced with powdered sugar, and thought them possessing qualities of their own of much value. Children, who are capital judges, will invariably like them very much. They have always been favourites here.

As to the very late Peaches I cannot speak much this year. They seemed comparatively flavourless, and so did the open-air Peaches. Why, who can say? We hear of actinic rays, and of heat and light producing rays being different, and in their action on the fruit producing results often unexpected. Very often a dull and cloudy summer, by arresting terrestrial radiation, will ripen our crops thoroughly, and also colour them more brilliantly than a succession of unclouded skies. How should we fare in an island like Guernsey, notorious for excess of cloud, and consequent equality of day and night temperature, but for some compensating and mysterious agency like actinism?

We can hardly hope for many such summers as the past one. Grapes have ripened well as standards in a favoured garden, while in ordinary seasons they are poor against walls. Under glass, on the other hand, they have generally coloured badly; but, as mentioned before, like early Peaches, forced Grapes were of good colour, showing some specific influence in the rays of the spring sun.

It may be an error, but I have an impression that a cordon ticketed "Duchess of Oldenburgh Nectarine" bore this fruit, at the proper season, at the top of the cordon, while, much later, some pale Peaches ripened lower down. The wire holding the ticket had pierced deeply into the albumen between the upper and lower portions, and caused the usual swelling above. Several Peaches are in bloom as I write, while the Pears which grew from blossoms after midsummer are perfect and ripe. According to the method of computing the degrees of heat needed to ripen each kind of fruit, which seems to me a valuable idea, these would have had about the usual amount of sun-ripening power.—T. BRIDGEMAN.

DESTROYING FUNGUS ON TAN—RINGING.

Boiling water will at once destroy the *Agaricus vulvaceus* (see page 368).

I tried on four trees the suggestion in the "Vine Manual," of ringing Vines, and the result in each case was that the bunches ripened about fourteen days before the others on the same Vine, and the berries were much larger, but the colour was deficient, and the flavour inferior.

It has been suggested to me by an eminent doct, that ringing and grafting act in a similar way. This is to me a new view of the effects of grafting. I shall try again, and if more successful will let you know the result.—B. A.

GEOGRAPHY FOR GARDENERS.

When a gardener is told the native place of a plant, if he knows the latitude, longitude, and elevation of that place, he has a good guide to the temperatures and moisture that plant

requires. A most handy and excellent guide to that knowledge is Keith Johnston's half-crown Geography, and as this is to be followed by a similar volume of Physical Geography, the gardener will then be fully furnished with guides to a knowledge of a plant's native climate.

THE COMMON BERBERRY.

It is readily admitted by those who have the best opportunity of giving a just opinion, that new or rare plants or shrubs are not in all cases improvements on older ones; in fact, it is too well known that many of the oldest shrubs and trees our gardens contain will hold their own against all comers. The Cedar of Lebanon, for instance, has not as yet been superseded by any Conifer in gracefulness of outline combined with adaptability of habit to any situation. Hollies, too, are pre-eminent for beauty of form, and when loaded with berries nothing can well be richer in appearance. Many other shrubs or plants met with every day are equally beautiful or interesting: and could we but be led to think so, the wild Broom of our commons and wastes is as beautiful as its namesake from the Canary Islands. There are, likewise, other plants whose merits we are slow in admitting, and some even which we are often guilty of absolutely despising, and it is to one of these that I now wish to direct attention. It is, in fact, one of the most despised shrubs which I know, and one that probably is not often met with in nurseries, owing to the small demand for it; yet it has its merits, and these, too, of a very high order—it is the common Berberry.

This plant is by no means popular; on the contrary, I have known many persons take great trouble to eradicate it where growing in hedges or copses bordering their fields, on account of its suspected tendency to infect the Wheat with Blight. Without giving any opinion on this point, it is certain that the numbers of the plant have been diminishing for some years. I do not advocate its being planted in hedgerows, mixed coppices, or dense shrubberies; but as a specimen shrub on the highly dressed lawn it has not often had that fair trial it ought to have, and its worth in that respect is far from being generally known.

Happening some years ago to be at the magnificent gardens of Drumlanrig Castle, I was much struck with the very handsome appearance a number of single specimens of the common Berberry presented on the much-varied and extensive lawn. A series of terraces surrounded the noble building, each adapted for a distinct style of gardening, but each on a very large scale, while beyond them the ground sloped more or less irregularly to the brink of a river of some size. On the opposite side of this stream the gently sloping ground was occupied by shrubberies, with glades and openings between, and in places the closely-shaven lawn was dotted with healthy and promising specimens of Conifers, mostly, I believe, Spruce Firs, each feathered to the ground, and presenting a more healthy appearance than those generally met with in England, except in the moist or mountainous parts. Mixed with these Spruce Firs, but in no way crowding upon them, were fine plants of the Common Berberry, which at the time I saw them, early in September, were loaded with their crimson fruit, and each plant in point of shape and appearance was a perfect model, yet they had received scarcely any pruning; indeed, I believe they only presented the natural form and appearance of the plant when left untouched. At the distance of 200 or 300 yards they looked like immense bushes of Fuchsias, and the beauty of their appearance was enhanced by contrast with the Spruce Firs adjoining. They completely threw into the shade all other deciduous kinds of Berberis that I am acquainted with, and showed what an ornamental object one of our common shrubs is capable of forming when allowed fair play.

It may be asked, was there anything peculiar in the soil and situation that assisted this shrub to assume so fine an appearance? So far as I was able to judge, there was not. The rainfall might be greater than in many other situations, and possibly nearly double that of the eastern counties of England, but the soil was not saturated with moisture. I have met with fine plants of the common Berberry elsewhere, loaded with fruit, and as handsome in shape as those in Scotland, but it is seldom the plant is allowed such a position as enables it to develop itself. More frequently we meet with miserable specimens of what are called the choice kinds, as *Berberis Bealii*, *Fortunei*, *japonica*, and others, while the British Berberry is driven out of most places at all dry, and left to struggle

amongst other dense bushes in a coppice, with a likelihood of its being found out, and large pieces cut from it to alleviate the suffering of some one afflicted with a disease it is said, to assist in curing. Whether useful or not in the latter capacity (which I believe it really is), it has no chance of taking that position as an ornamental shrub which it is capable of attaining. Perhaps when the Antipodes are ransacked of their vegetable treasures, we shall find out how many ornamental plants we possess at home, and cultivate them accordingly.—J. ROBSON.

THE GOLDEN QUEEN MELON.

In answer to "W. H. C.," I procured a packet of seed from Mr. Turner, of Slough. My seed grew, and proved to be very true. The fruit is quite equal to the description given of it in various advertisements. The plant is a moderately strong grower and a free setter. Fruit medium-sized, of a beautiful rich lemon colour, and irregularly netted; flesh pale green, very tender, and melting; skin remarkably thin. The flavour is most exquisite; indeed, I think this the queen of Melons.—G. LOCKIE, *Gardener to F. W. Barker, Esq., Court Gardens, Great Marlborough.*

I AM rather astonished at the remarks of "W. H. C." in the Journal of November 5th, in respect to the above valuable Melon. I am inclined to believe that he is in fault and not the Melon, and to prove this I may mention that I purchased a packet of seed, for which, like your correspondent, I also paid 2s. 6d. As I had only a small two-light frame, measuring 6 feet by 6 feet, to spare, I put two plants of Golden Queen under one light, and two of Beechwood under the other. From the former I gathered twelve of the finest Melons I ever could wish to see, averaging fully 3 lbs. each, which I consider large enough for any gentleman's table. They were of an almost globular shape, beautifully netted, and the flavour, as far as my estimation goes, perfection.

I have saved all the seed I can, as I candidly think it the finest Melon I ever grew. I would advise "W. H. C." to give Golden Queen another trial previous to discarding it, and for which, if he favour me with his address, I shall be very glad to send him a few seeds. The Malvern Hall I have not yet grown, but believe it to be first-rate, consequently I intend trying it another year.—O. TAYLOR, *Sunlairs, Helton, Roxburghshire.*

I MAY mention for the encouragement of your correspondent, who seems to have been singularly unfortunate, that in the competition for the best Melon at the Kelso Horticultural Society's Exhibition, in September last, Golden Queen Melon obtained the first prize; and judging from the interest shown both by the censors and visitors, it appears, doubtless, that this beautiful Melon is to become a general favourite.—GEORGE WEMYSS, *Springwood Park.*

DURING the past season I have grown eight plants of the Golden Queen, some of them in pits and some on hotbeds, and in both ways they set and matured an abundant crop of fine fruit. I also grew five other sorts of Melons; all of them had the same treatment as the Golden Queen, and all produced fair crops, but both in flavour and appearance Golden Queen was superior to any of the others; it is, in fact, the best and prettiest Melon I have ever seen. The soil in which I grew it and all the other varieties was good, strong, turfy loam, put along the back part of the pits and frames to the depth of about a foot, and 2 feet in width. The plants were within a foot of the back, and were trained towards the front on wire netting, placed as far from the glass as to allow the lights being pulled up and down without injuring the leaves. As a further proof of its good quality, I may state that at the Alwick Horticultural Society's Show in September last, the first and second prizes were awarded to it from different growers against a splendid-looking lot of Melons.—R. DOWIE, *The Gardens, Chillingham Castle.*

[W have other communications signed "D. I.," "R. S.," &c., all testifying to the superior excellence of the Golden Queen Melon, but we think that the above are sufficient to place before our readers, and to convert "W. H. C."]

SCALE ON ORANGE TREES.

AFTER trying numerous plans, such as scraping off the insect, and washing the parts with various insect-killing preparations,

without the slightest success, we determined on cutting off every branch, and leaving the stems bare, and then scrubbing continually with soft-soap and water. This, after some months, the stems being placed in the open air in winter, succeeded, and the pest and eggs having been eradicated, the insect has never appeared since. This year we have had five or six dozen of Tangierine Oranges to a plant, and most of them are twice the size of those sold in Covent Garden. The trees, after having been forwarded in a hothouse, were placed in June in the cylinder vineries, and the fruit is now ripe. Most of it has been gathered.—OBSERVER.

FRUIT TREES OUT OF DOORS IN POTS.

RECENTLY, in "Doings of the Last Week," you spoke at some length on the planting of stationary miniature fruit trees. Now, I have a great desire to cultivate these miniature trees, but, being a working man, my garden and my purse are both limited; but they say, "Where there is a will there is a way," and I think there is if one make up one's mind to persevere.

I am a quarterly tenant, and should not, therefore, like to plant my garden with trees, and then, perhaps, have notice to leave, or have my rent raised after going to the expense myself of beautifying my landlord's premises. My means will not allow me to build a small orchard house, neither should I like to do it unless I had the place on a lease.

If such trees could be grown in large pots in the open air, and if a spare attic could be used for their reception during the most severe part of the winter I could manage very well, and if I should have occasion to remove I could easily take them with me.

If such a mode of cultivation is possible, would you be kind enough to give me a few useful remarks, and name a few of the hardiest kinds, and how long it would be before I should have fruit?—DOUGAL McDUGAL.

[You may do what you propose without an orchard house, or a spare room for wintering, if you confine your practice, at least at first, to the hardier fruits, as Cherries, Plums, Pears, and Apples. Of course, from such trees in pots you would not gather nearly the quantity of fruit that you would from trees planted out, but then you could have four or five of these pot trees in the same space. To save labour we would advise you to have pots or small barrels from 12 to 15 inches in diameter. We have seen oyster barrels used when plunged.]

From our advertising columns you will see what you can obtain small pyramidal or bush trees for, and which, having been grown a year or two, would, if carefully potted, fruit the next season. In your circumstances we would select what are called maiden plants—that is, with a little more than one year's growth from the bud or graft, and with several shoots each, so that you can mould them into any requisite or desired shape. These we would pot in rich leamy soil at once, ramming the soil hard, plunge the pots in the ground up to the rim, and then mulch all over to keep out frost. The shoots we would not cut much back, as we would want the buds left to make short fruit spurs in summer for next year's bearing. We have potted small Plum and Cherry trees in February with one year's growth from budding, and, treated as above, the trees were well loaded with fruit in the following year. In summer the trees will want watering, but mulching will render the frequent waterings less necessary; and when the fruit is gathered the pots should be lifted, all roots that have come through cut off, and be plunged again after being fresh soiled on the surface.

Pyramids at first might be 30 and dwarfs 36 inches apart. A net in winter and summer, and frigidario in spring, would protect from frost and birds. Let us hear again when you commence, and when you are in the least difficulty.]

PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

PASSIFLORA CINNABATA (Charly-fringed Passion-Flower). *Nat. ord.*, Passifloraceæ. *Linn.*, Pentandria Trigynia.—Requires a cool greenhouse. Native of Pernambuco, in Brazil. Flowers purple.—(*Botanical Magazine*, t. 5373.)

ACRIDOCARPUS NATALITICUS (Port Natal Acridocarpus). *Nat. ord.*, Malpighiaceæ. *Linn.*, Decandria Digynia.—A climber. Native of edges of woods in the Natal Colony. Flowers yellow.—(*Ibid.*, t. 5738.)

MASDEVALLIA VEITCHIANA (Veitch's Masdevallia). *Nat. ord.*, Orchidaceæ. *Linn.*, Gynandria Monandria.—Native of the

Peruvian Cordillera. Introduced by Messrs. Veitch. Flowers orange red. Cool greenhouse plant.—(*Ibid.*, t. 5739.)

FUCHSIA COCCINEA (Scarlet Fuchsia). *Nat. ord.*, Onagraceæ. *Linn.*, Octandria Monogynia.—This is the true species, and not that usually grown in gardens as *F. coccinea*. It was recently found in the greenhouse of the Oxford Botanic Garden. Soon after its first introduction in England the still hardier species, *F. magellanica*, arrived from Terra del Fuego, usurped its name, and superseded it in our gardens. Probably a native of Brazil. Flowers pale crimson.—(*Ibid.*, t. 5740.)

APHELANDRA NITENS (Glossy-leaved Aphilandra). *Nat. ord.*, Acanthaceæ. *Linn.*, Didynamia Gymnospermia.—Native of Guayaquil, in New Granada. Introduced by Messrs. Veitch. Flowers scarlet. Leaves' upper surface glossy, under surface reddish purple.—(*Ibid.*, t. 5741.)

GENTIANA PYRENAICA (Pyrenean Gentian). *Nat. ord.*, Gentianeæ. *Linn.*, Pentandria Monogynia. Native of the Pyrenees and Alps at 5-8000 feet elevation. Flowers green externally, deep blue internally.—(*Ibid.*, t. 5742.)

GLADIOLUS—*Lady Alice Hill*.—"Amongst the most marked of the recent improvements which have been made in the Gladiolus, has been the introduction of numerous finely-striped varieties. The present variety was raised by Mr. Standish, of Ascot, and was awarded a first-class certificate by the Floral Committee in October, 1867. It forms a fine bold spike, and the individual blossoms are not only stout, well-formed, and symmetrical, but well-placed on the spike. The colour is a pale rosy tint, boldly flaked with purplish rose, the throat being flamed with deep rosy violet. Mr. Standish has been a most successful raiser of Gladioli, and the present variety, of an entirely novel character, will add to his well-earned reputation."—(*Florist and Pomologist*, i. 241, 3rd s.)

CHRYSANTHEMUMS.

MR. SALTER'S NURSERY, HAMMERSMITH.—The show house at this establishment presents just now an extremely gay appearance, as the extensive collection of Chrysanthemums for which Mr. Salter is celebrated far and wide will soon be in full flower; and even now most of the varieties are in great beauty, while from day to day others will expand. The display is not merely superior to that of last year, which, from the lateness of the autumn, was certainly unfavourable to Chrysanthemum shows generally, but as a whole not less effective than those of former years, whilst in the varieties individually there is a marked advance as compared to those then in existence. Unfortunately, our visit to this nursery, three or four days ago, was rather early for the varieties intended to be sent out next year to be seen in perfection, and accordingly the number of such that can be noticed at present is rather limited, but there are others which Mr. Salter considers very promising and which may be referred to on a future occasion. Of those which were sufficiently forward, Golden John Salter, a sport of John Salter, equally fine in all its characters, and differing only in being of a rich golden colour, certainly of first-rate merit. Lilac Beverley, another sport, was noticed last year; it only differs from its prototype in colour, being the same in form and all other respects. At first it is white tinged with lilac, but afterwards becomes deeper in colour. Two seedlings, as yet unnamed, are also fine incurved flowers, one being very large, sulphur-tinged white, the other claret-coloured, turned up with yellow. A third seedling has a finely incurved rose-coloured flower, and another named Stellaris, buff tipped with yellow, resembled Cherub in form. There is also a new Anemone-flowered variety called Princess Charlotte, with lilac flowers, the tops of the quilling tipped with yellow. The foliage of this was stiff and very dark-coloured.

The varieties sent out in the spring of the present year were mostly noticed in reports at the time of their first appearance. Of these Lord Derby, dark purple, large, and beautifully incurved is, on the whole, the finest, and a peculiarly bold flower. Princess of Teck, very pale flesh, on the other hand, is very delicate in colour and very beautiful. Bronze Jardin des Plantes, a sport of the well-known and beautiful yellow Jardin des Plantes, bronzed orange, is another very bold and fine flower; and not less remarkable is Princess Beatrice, lilac tipped with blush, a large flower, splendid in exhibition stands wherever we have seen it this year. Guernsey Nugget, primrose yellow, is large, very pleasing in colour, and likewise a fine show variety. Mrs. Huffington, like Aimée Perdre, from which it is a seedling, but more distinctly and darkly tipped, though

not very large, is extremely beautiful. Other new varieties in good bloom consist of Baron Beust, reddish chestnut; Staffa, yellow; Mrs. G. Rundle, pure white; Volunteer, dark purplish crimson; Miss Maréchaux, white, tipped with lilac; and Enamel, bluish. Lady Godiva and Le Grand when we saw them were not fully out.

The Japanese varieties which are so singular in their various forms, and which promise to become so useful and ornamental for conservatory decoration, though veritable abominations to those who judge by the florists' standard, being later, many of them were not so far advanced in blooming as to admit of description. Red Dragon and Daimio were extremely showy, and left no room to doubt what a splendid effect they were capable of producing in conservatory groups. Roseum album, another, was beautiful in colour, crimson tipped with white when in a young state, but afterwards becoming paler. Yeddo Lilac, with the ribbon-like florets curving inwards and forming a ball; and Sulphureum, of similar form, are also effective. Wizard, dark maroon; and Robert Fortune, were not out. Others consisted of Nagasaki Violet, rosy violet spotted with white; Prince Satsuma, very large, yellow; Ne Plus Ultra, flat, orange red; and Tarantula. Gold Thread, a quilled variety, lilac at first, but becoming yellow was scarcely sufficiently forward to exhibit its true colours; but Dr. Masters and Dr. James Salter, two new varieties, were both in excellent condition. The former is very large and showy, orange, tipped and rayed with yellow, and of stiff upright growth; the latter one of the tasselled kinds having broad ribbon-like florets of a delicate lilac colour. It is very free-flowering and would form a handsome specimen plant for conservatory decoration. Hero of Magdala, blood red, promises to be very showy; and of Giantess, pale lilac fading off to white, the same may be said.

Near the entrance to the show house is a pretty piece of what bears considerable resemblance to mosaic work formed of various Echeverias, Sedums, Sempervivums, the pretty blue-tinted Kleinia repens, and Pachyphiton bracteosum, with the grey green Thymus lanuginosus, and the bright green Saxifraga hypnoides minor, as a ground carpeting. The variegated common Stonecrop was very ornamental out of doors in the alpine garden; also, the larger variety of Saxifraga hypnoides, which keeps green in summer on banks where grass is burnt up.

ROYAL HORTICULTURAL SOCIETY.

NOVEMBER 17TH.

FRUIT COMMITTEE.—G. F. Wilson, Esq., F.R.S., in the chair. At this meeting there were various prizes for fruit offered. In Class A, for the best three dishes of dessert Apples there were eight exhibitors. The beauty of the specimens in all the collections was greater than is usually seen, and some of the specimens were very handsome, but it was remarked that for fruit of so much beauty there was not a proportionate amount of flavour. The first prize was awarded to Mr. Ruffett, gardener to Lady Palmerston, Brockett Hall, Herts, for Cox's Orange Pippin, Cockle Pippin, and Cornish Gillsflower; and the second to Mr. Earley, Digswell, near Welwyn, Herts, for Cockle Pippin, Cox's Orange Pippin, and Sam Young.

In Class B, there were five exhibitors for the prize offered for the best dish of Knight's Monarch. One dish was disqualified, being found to be Ne Plus Menris, and another for being decayed. Those exhibited by Mr. Sidney Ford, of Leonardslee, were magnificent specimens, but, unfortunately, unripe, and to them a special certificate was awarded, and no other award was made.

Class C, was for Hayshe's Victoria. There were only two exhibitors, and the second prize was given to that shown by Mr. John Garland, gardener to Sir T. D. Acland, Killerton, Exeter, the first being withheld.

Class E, the best dish of any variety of dessert Pears. There were no less than 22 exhibitors, and the specimens generally were very good. The six Winter Nelis of Mr. Garland, of Killerton, weighed 2 lbs. 11 ozs., which for that variety was a great weight; and a fruit of the Doyenne du Comice shown by the same gentleman weighed 15½ ozs. The first prize was awarded to Mr. Garland, for Doyenne du Comice, and the second to Mr. Mills, Wycombe Abbey, for Winter Nelis.

Mr. Jackson, Nurseryman, Blakedown, Kidderminster, sent a collection of seedling Apples, but as none of them possessed any properties that were considered as acquisitions, the Committee did not approve of them. Mr. Brown, Elmdon Hall, Birmingham, sent two dishes of Blenheim Pippin, one containing fruit much larger and earlier than the other, being a month difference in the time of ripening. This can only be accounted for by the influence of the stock.

Mr. Gilbert, gardener to the Marquis of Exeter, Burghley, sent a brace of the Telegraph Cucumber, which for the season was considered very good, and received a special certificate. Mr. Osman, gardener to R. Holland, Esq., Stanmore Hall, sent a Green-fleshed

Melon, the fruit of the Gnava, and a dish of Quinces. The Melon for the season was very well flavoured. Mr. Foster, Pitlington House, Leigh, Essex, sent good bunches of Royal Muscadine and Miller's Burgundy Grapes, grown in the open air, and which were well ripened and of excellent flavour. Mr. Forsyth, gardener to Baron Rothschild, Gunnersbury, sent a fruit of Smooth Cayenne Pine Apple, and Mr. Westcott, gardener to the Duke of Cleveland, at Raby Castle, sent a fruit of the same variety, and both being very handsome specimens, they each received a special certificate. Mr. Westcott, sent a Scarlet-fleshed Melon called Raby Castle.

Messrs. Lane & Son, of Berkhamstead, sent a splendid collection of Grapes grown in a cool orchard house, which for size of bunches and berries could not be surpassed, and a special certificate was awarded. Messrs. Rivers, of Sawbridgeworth, sent a dish of very fine Tangerine Oranges, fully ripe and of delicious flavour, which received a special certificate. W. L. Banks, Esq., Ealing, exhibited the fruit of Ficus elastica, and a drawing of the plant showing the mode of fructification. Mr. Downing, gardener to T. Grissell, Esq., Norbury Park, sent good specimens of Pomegranates. Mr. Ruffett exhibited fruit of St. Martin's Quetsche Plum, which was rather past. Mr. Stevens, of Trentham, exhibited Fleming's Seedling Pear, which the Committee did not consider equal in merit to other sorts sent along with it. Mr. J. Snow, of Saltram, exhibited a seedling Pear which proved to be Vicar of Winkfield. Mr. Eckford, of Colehill, sent four very nice, small, white-spined Cucumbers named Winter Favourite.

Messrs. Barr & Sngden filled a table the entire length of the exhibition-room, with a very complete and interesting collection of ornamental Gourds, to which a special certificate was unanimously awarded.

The Chairman read a communication from Mr. Dewdney, Pigham Mill, Dorking, relative to the Black and White Grapes grown on an open wall, which he exhibited at the meeting of October 20th. In this Mr. Dewdney stated, that at the conclusion of the meeting, having had a conversation with a member of the Council, he was asked to write an account of his mode of cultivation, and he had done so, not with any view of pointing out how to grow Grapes, but simply to relate the following facts:—

"In the years 1839 and 1840 I built the house I now live in; against an angle of this house some 15 yards long, and with a south-east aspect, I made a Vine border by removing the soil and filling in with brick and mortar rubbish from a very old building, whole bones, and old shoes, to the thickness of 1 foot. I then put 8 inches of the soil on this mixture. In this border I planted a Black Grape (the Black Prince), a White Frontignan Grape, and a Fig tree, all of which have thriven entirely to my satisfaction. In 1846 I gained the 2nd prize for Black Grapes at a local show, beating three men who exhibited Grapes grown under glass. On the end of this border, in 1841, I made a bed 8 feet square and 22 inches deep; the sides were slate (one slab), and the bottom was paved with similar slate slabs, so that the roots of a Vine could not escape. I filled in this bed as follows:—In the bottom I put pieces of chalk to the depth of from 4 to 6 inches, and broken bricks for drainage; I then filled up with broken bricks, and mortar rubbish, whole bones, old shoes, pig's hair, and about ½ bushel of charcoal, and in this bed I planted a White Frontignan Grape which has produced a good crop every year. Some bunches from this Vine I exhibited on the 20th of October. I should observe that I did not mix any earth with the compost. This Vine has thriven, and continues to do so, rods from 15 to 25 feet long a very year, a specimen of which, cut 10 feet from the ground, I send with this paper.

"I also send for the inspection of the Council, the soles of some old shoes, which, on removing a Pear tree last Saturday, were dug from under its roots, and which tree was planted five years ago; and the examination will, I think, establish beyond doubt the great fertilising and lasting power of leather as a manure. A few years since I laid bare a Vine border when I found some soles of shoes similarly encompassed by the roots of the Vine.

"Mr. Whiting, I believe, will fully corroborate me as to the luxuriant growth of my Vines."

FLORAL COMMITTEE.—This was one of the best meetings of the season, both fruit and flowers were excellently represented. Mr. Turner, of Slough, introduced some new variegated Zonal Pelargoniums, which astonished the meeting. This successful exhibitor has shown himself in this, as in every other class of plants which he cultivates, a perfect master. His collection was certainly for distinctness and high colour much in advance of what has been before exhibited, and, considering the time of year, most beautiful. One fact has been decidedly confirmed, that for decorative purposes the autumn and spring are the best seasons for developing the rich colours of the foliage. First-class certificates were awarded to three of the finest specimens, of which there were duplicates—Mrs. Headley, Miss Rutter, and Miss Christine Nilsson. In the collection were Hayes Rival, Mrs. Hugh Berners, Grand Master, very distinct, Senior Warden, Mr. Rutter, and Echo, golden-edged varieties; Excellent and May Queen, two good examples of the silver-edged Tricolors, and Bright Star, a Bicolor, with brilliant scarlet flowers and white-edged foliage, also May Queen of the same class. Mr. Turner also sent a small basket of young plants of Zonal Pioneer, which he sent out in the spring, and which proves itself to be a plant of first-rate quality. A special certificate was awarded for the collection. A group of Chinese Primulas of various tints of colour was likewise exhibited by Mr. Turner.

Messrs. Veitch exhibited a very fine collection of Orchids, several beautiful hybrids, the result of Mr. Dominy's persevering skill. Phajus irroratus, one of the seedlings, received a first-class certificate; Oncidium cucullatum phalaenopsis, a first-class certificate; Pleione

Reichenbachiana, a first-class certificate; *Oncidium Forbsii*, a first class certificate; and *Vanda carulea*, with twenty-five flowers, a special certificate. The group of Orchids was awarded a special certificate. *Dichorhiza mosaiica*, a beautifully-grown ornamental-foliaged plant, had likewise a special certificate. Messrs. Veitch also sent specimens of a variegated *Cress*, and small plants of *Rue* to make a contrast with its dark foliage—plants useful for a winter garden. Mr. Thomson, gardener to the Duke of Buccleuch, the President of the Society, sent extremely fine cut spikes of *Vanda carulea* and *Renanthera coccinea*, which received a special certificate. Mr. Thomson sent a letter, which most simply explained his successful mode of cultivation.

From the gardens, Chiswick, came a fine collection of seedling varieties of *Coleus*, distinct and beautiful, much in advance in colour of what have been sent out. First-class certificates were awarded to *Coleus* Duke of Edinburgh, Princess of Wales, Princess Beatrice, Her Majesty, Prince Arthur, and Albert Victor. We understand these will very shortly be offered for sale by auction. Mr. Williams, Holloway, sent a very excellent collection of Orchids, of which *Oncidium holochrysum* and *Oncidium Forbsii*, received first-class certificates. *Pteris serrulata corymbifera* was likewise awarded a first-class certificate. A special certificate was awarded for the collection of Orchids.

Mr. Salter, Hammersmith, sent seedling *Chrysanthemums*. Among the Japanese varieties, Dr. Masters was very fine, and received a first-class certificate, as also Hero of Magdala. Princess of Teek, a fine, compact, pale silvery flower, one of the incurved varieties, and Pink Perfection new in shade of colour, a most promising variety, were awarded first-class certificates. One of the Japanese varieties, James Salter, a pale pink or bluish flower with very broad "petals," the flowers evidently suffering from change of temperature, was very beautiful, though not noticed. This is decidedly one of the best of the Japanese race.

Mr. Wiggins, gardener to W. Beck, Esq., sent a collection of *Cyclamens* and *Primulas*. A special certificate was awarded the two collections. Mr. J. Mills, gardener to Dr. Pattison, received a special certificate for two Orchids sent by him, *Odontoglossum Alexandrie* and *Odontoglossum triumphans*. Mr. Green, gardener to W. W. Saunders, Esq., was awarded a first-class certificate for *Asparagus decumbens*, an elegant plant most useful for table decoration.

Messrs. E. G. Henderson sent *Gymnogramma lanceana* corymbifera, first-class certificate; also small specimens of *Lucy Grieve* Variegated Zonal *Pelargonium*, Charming Bride, and Silver Cloud. Messrs. Downie, Laird, & Laing's collection of small Bronze Zonal *Pelargoniums* was awarded a special certificate. Messrs. Smith, of Dulwich, sent Bronze *Pelargonium* Sybil.

A group of *Cypripedium insignis* from the garden of the Society, with an abundance of flowers, received a special certificate. The silver Flora medal was awarded to Mr. Forsyth, Stoke Newington, for twenty-four cut specimens of *Chrysanthemums* of great merit. The other competitors for this medal were Mr. Dickens, Chelsea, and Mr. Gunn, Chelsea. Mr. J. George, of Stamford Hill, was awarded a special certificate for twelve cut specimens of *Chrysanthemums* of first-rate quality. Mr. George also exhibited twelve varieties of the *Anemone*-flowering *Pompons*, and a seedling *Tropaeolum compactum*, which, from the lateness of the season, could not display its merits.

GENERAL MEETING. — J. Bateman, Esq., F.R.S., in the chair. After a list of donations of plants, &c., had been read, the following new Fellows were elected—viz., Lady Lawrence, Miss Blakeley, Mrs. Cousins, and Messrs. A. Henderson, A. Cathell, and T. Higgs. The awards of the Committee were then reported, after which Mr. Bateman offered some remarks on the Orchids.

Mr. Bateman expressed his regret that the Rev. M. J. Berkeley had not recovered sufficiently to attend the meeting, and that he himself was unable to supply his place as regards the plants exhibited, with the exception of his own special favourites—the Orchids. He could not, however, but congratulate the Fellows present and horticulturists generally, that in the midst of such excitement as that which now prevails in the country, there should be such a fine display. He had frequently found fault with the Floral Committee for the frugality of their awards; but on this occasion there had been freely bestowed, especially upon Orchids, which, of all the candidates which had sought the Committee's favour, were decidedly at the head of the poll. The first plant he had to notice was *Phione Reichenbachiana*, which really might be considered one of the autumn *Crocuses* of the Himalayas, and of which the pseudo-bulbs were very singular. Although he detested hybrid Orchids, he would still mention that Messrs. Veitch exhibited several of these, and among them *Cattleya exoniensis*, a beautiful autumn-blooming Orchid. Another hybrid, also very beautiful at this time of year, was *Cattleya Dominiana*. With reference to *Odontoglossum Alexandrie*, exhibited by Dr. Pattison, of St. John's Wood, he was glad to see it vindicating the choice of the name made for it; there was also from the same gentleman *Odontoglossum triumphans*, which, though well grown and flowered, was not equal in point of variety to some others of the same species which he had seen.

Mr. Bateman then protested against the growing practice among some nurserymen of tacking on additional names to those of certain plants—a practice which only led to confusion when there was already a good generic and specific name, and he gave several instances in which such additions were unnecessary. Two of the most interesting

subjects before the meeting were the spikes of *Vanda carulea* and *Renanthera coccinea*, sent by Mr. Thomson, the President's gardener at Dalkeith. *Vanda carulea* was a most beautiful Orchid from the Himalayas, and as regards this, there had been a very vigorous competition between Mr. Thomson's spike and that of Messrs. Veitch's plant, and whilst the former was the finer in colour, it had only twenty flowers, but Messrs. Veitch's, he believed, had as many as twenty-five. As to the *Renanthera*, he (Mr. Bateman), could hardly look at it without emotion, for without it he probably never would have been an Orchid-grower. He then related that when an undergraduate at Oxford he saw it in the nursery of Mr. Fairbairn, who had succeeded in flowering this plant, and he bought a specimen for a sum which might be considered extravagant for an undergraduate. He failed, however, as might be expected, in making it flower, and it was only after twenty-five years' cultivation that he succeeded by an accident. This *Renanthera*, Mr. Bateman continued, will never grow and flower in promiscuous collections, but put it in ainery, a greenhouse, in any house where it will have plenty of light and sun—in fact, the conditions of a Chinese climate, and ten to one it will flower. He would in conclusion just direct attention to a beautiful-berried branch of the Coffee plant, which had arrived too late to come before the Committee, and which was sent by Mr. Pickersgill Cunliffe, of Hooley Hall, Croydon. (We were informed that this plant is 8 feet high, and has ninety-six berried branches.) Mr. Bateman closed his remarks by announcing that the next meeting would take place on the 15th of December.

JERSEY FOR WINTER.

As Jersey is as good and pleasant for invalids in winter as for pleasure-seekers in summer, a few words about it may not be deemed superfluous, now that the glowing warmth of summer has given place to the cool breezes of autumn, and that brown and yellow, taking the place of green upon the scantily covered trees, remind us of cold, trying winter soon to follow. Charming as our little island is during the bright warm weather, it is yet more valuable as a winter residence to those who suffer from the inclemency of our British climate nearer the parallel of London. Mild in its winters, yet not too enervating, seldom intensely wet for a whole day together, with roads which dry up quickly, genial, health-giving breezes, and the delicious sea air, I think there are few places better in all points for the invalid, the convalescent, or those who are troubled with the John-Bull-like, not-unnatural horror of chilling fogs, benumbing frosts, and bitter ice and snow.

Those who visit Jersey at any season, but especially late in the year, would do well to guard against discomfort in travelling by reaching Southampton some hours before the vessel starts. The route *via* Southampton is the best for most localities, and for all persons who dread a long sea voyage. That by Weymouth gives fewer hours upon the water, but the extra hours by the longer route tell little in discomfort, as those which elapse before reaching the Needles in going, or after passing them in coming back, glide smoothly enough to be pleasant even to the most squeamish. The voyage from London direct is too lengthy to be pleasant to any but very good travellers, so the journey by way of Southampton is for most persons fittest, and to ensure comfort in that, it is necessary to secure a good berth on board ship. Oh, the wretched discomfort to which ladies are sometimes subjected who come down by the mail train at night, and go on board just before the ship starts! Visitors who rush over to Jersey for short holidays between May and October, called in the island from their vivacious enjoyment of their short respite, "the live O's" crowd on board in noisy tumult to the great detriment of quieter persons who are less able to make their way; then those who have omitted to secure accommodation may have to lie on the cabin floor all night (and be it remembered the bad air falls the lowest), or, worse still, to remain on deck all night, subject to the inclemencies of the weather and other discomforts. During the months when most visitors seek the island it is advisable for ladies, especially if they have children with them, to write to the agent or to the stewardess on board and bespeak the required number of berths, and at all times, as stewards and agents are not immutable, to leave London, if London be the starting point, not later than 5 p.m., and go on board at once, secure berths, and pin tickets upon them. Then, with a clear conscience and the hope of a little rest at night, they may go to their hotel, inspect the town, or while away the time as best they can. As Southampton is but a dull place, and visits to hotels generally dull too, perhaps it is about as pleasant as anything to go on board at once, sit down on deck, and quietly watch the curious bustle of dock activity around, go down into the cabin and have tea as soon as it is ready, and then lie down

and commence the early portion of such a night's rest as the ever-restless sea and the hubbub on board will permit. N.B.—In tolerably calm weather a sofa is most pleasant, because most airy, but when the sea is very rough a berth presents least chance of being tossed out upon the floor, and those at the top are the most airy, only a little difficult to climb into, which is generally obviated by the offered help of a small set of steps.

Just as the quiet voyagers compose themselves to sleep the mail train passengers come rushing on board with clang and clamour, stamping of boots, knocking about of luggage, and much bustle and noise, and then about 12 p.m. the steamer starts.

The voyage is only broken by reaching Guernsey, generally about nine in the morning, when the boat stops a short time to put out and take in passengers and packages, and then onward again. The view of St. Peter's Port, rising on a steep hillside, the quiet ripple of the sea within the harbour, and the quaint antique-looking Castle Cornet close by, all seen in the light of the bright morning sun, are very attractive, and if the sea is calm, or the traveller a good sailor, it is pleasant to remain on deck from thence to Jersey.

On approaching the island, the first object which becomes distinct in the lessening distance is a prominent rock at the south-west corner, showing in its outline an unmistakable likeness to Louis Philippe, but it is less distinct now than it was twenty years ago, and perhaps the work of many years may do away with it, as with French ways and manners of his bygone time. If the day be bright, with the sun shining, the various tints of the vast masses of rock forming Jersey strike the visitor as very beautiful. The grey and red granite, the warm colour of the common rock, the patches of white sand in bays and inlets, the mixture of faded pink and bright brown of the heather upon the heights and slopes, and the luxuriant vegetation down to the very water's edge, make a variety in the landscape most pleasing to the eye as the boat steams round, until it crosses St. Aubin's Bay, a really splendid half-circle of silvery sand, surrounded by luxuriant heights, with handsome villa residences, prettily wooded slopes, and in the distance verdant hills. There are few days in this pleasant climate during a portion of which the landscape does not show a bright and smiling face.

At the extremity of this fine bay lies St. Heliers, a large, crowded town, smoky, straggling, and surrounded by high ground. Here we enter the harbour, which is large, handsome, and convenient at high water, but much less useful when the tide is out, for then passengers have to land in boats. The landing places are about as damp and slippery, crowded and bustling, well-managed in some respects and badly in others, as most places of the kind. The passengers have, however, scarcely landed when they begin to realise the pleasantness of a delightful climate; half an hour after the rain has ceased the streets and roads in all but the deep valleys are dry enough to make walking agreeable, and it is unusual if the sun do not peep out to welcome the new comers, lighting up the rugged heights, picking out the tints of the rock in bright distinctness, and shedding a genial warmth, which fully compensates the generally slight discomforts of the journey.

The civility, too, of the calmen, and all people of that kind strikes the visitor, especially the nervous invalid, as very reassuring; overcharging and impertinence are quite unusual. The hotels are good upon the whole and moderate in their charges; those about the pier and the Royal Square are much frequented by commercial visitors. The British Bree's boarding house, and a great novelty, the Imperial Hotel, are much used by families. At the Pomme d'Or the appointments follow the French fashion, and it is said the terms are very moderate.

The luxuriance of the vegetation, the productiveness of the gardens, the verdure of the little fields, and the manner in which every scrap of land is economised, are no less wonderful than interesting to those who have been accustomed to England's broad acres, her highly cultivated but often disappointing gardens, and lavish expenditure of land and capital. In a climate and on a soil where all choice things might be grown in luxuriant profusion Pears receive, to my idea, too exclusive attention. Jersey Pears, as all know, are good, and the culture of them is very profitable, but it seems to me quite a mistake to grow them to the exclusion of most other choice garden crops. They are, however, the product of the place, and as such deserve and must have a special notice.

Vegetables in Jersey are not so cheap and abundant as they

ought to be where so favoured with a light productive soil, the absence of injurious frosts in winter, the genial moist air, and general slope of the island towards the south. In spring the markets are badly supplied with choice vegetables. Asparagus is fine and large, but very dear, and of that handsome large white sort which so splendidly fills a dish, but affords little of the delicious succulent portion which most amateurs who grow their own Asparagus so much delight in. The fat seaweed ever within reach, the grey sand, rich with mud, to be had for little beyond the eating (which, by-the-by, is rather dear in Jersey compared with other remote places), and the rich friable earth which forms most gardens here, offer great facilities for making good, productive Asparagus beds, only needing the addition of stable manure; yet in the gardens of all the three houses which we have occupied, we have had to make Asparagus beds, never having found a vestige of one in any of them. In seeking for a home for the last ten or twenty years, or so, on and off, we have looked at so many houses that it has become a byword in the family to indicate indefinite locality by "the house we looked at," and we have always made a large garden a desideratum, yet I can scarcely recollect finding good Asparagus beds in any. Cauliflowers and Broccoli, on the other hand, are excellent and abundant, cheaper and much better than in London. In the height of the season I have known nice heads, from 4 to 6 inches across, sold seven or even nine for 6d. This was an extreme chance, such are often sold three or four for 6d., and fine large ones about 6d. each; they are grown in both fields and gardens, manured abundantly with seaweed, also with farm and stable manure. Great quantities are shipped for England.

The celebrated Jersey Kale, sometimes called the Jersey Cabbage, makes itself conspicuous in all country rides. It is not grown as some one facetiously stated to pack the butter; for that purpose leaves of Cabbages of more delicate growth are used, but to feed the cattle. Its tall, stout stems and rampant growth of large luxuriant leaves make it a ruinously exhaustive crop for gardens; it is often grown in orchards, and there I suppose the earth is abundantly manured for it, or I should much doubt the economy of giving it room. Upwards of thirty years ago something curious of the Cabbage tribe was introduced, I think by old William Cobbett, by means of some London seedsmen. It was called the *Cesarean Cow Cabbage*, and seed packets containing about twenty seeds were sold at 1s. each, its merits being vaunted as something wonderful for cattle-feeding. These packets contained seed of the Jersey Kale, *Cesarea* being the island's ancient name. Many jokes were made on the possibility of growing it in city gardens, and letting the cow upon the house-top browse upon it; and I believe a good many packets of the seed were sold at the price set on them, but the Kale never made its way in England. The leaves are stripped off for fodder, I believe they come in usefully as green food, but I doubt if they compensate for what they abstract from the land. Excellent Cabbages are, however, grown in Jersey; the favourite kinds are Nantais, Imperials, and Nonpareils; they command good prices in the market, varying in common seasons from 1d. to 3d. each. Brussels Sprouts do not receive fair play in Jersey. I suppose from the time they occupy the ground, space is grudged them, for they are never brought to market and sold by measure as in England, but a stem is dragged up, with all its little Sprouts about it, and sold at a high price.

Sea-kale, again, is little grown, although the fat sand and the seaweed manure, and the light earth to grow it in, offer the very best facilities for bringing it to full perfection. I have never had any in England so fine as I have cut here, one weighed three-quarters of a pound—not lanky and over-grown, but short, thick, young, succulent and tender. Yet this delicious vegetable is brought from the West of England to the Jersey market, and sold at London prices.

Root crops are abundant, good, and moderate in price. Lettuces of all the Cabbage kinds are fine and tolerably moderate in price, but good Cos Lettuce are seldom seen. Radishes, Cress, and similar crops occupying the ground for but a short time, are cheap.—E. W., Jersey.

VIOLA CORNUTA AS A BEDDER.

THIS has been a trying year for the Violas, and some people appear inclined to give them up, while others write favourably of their continuance.

For my part I have found them succeed remarkably well, not

having lost twenty plants out of a thousand, and they never were watered except at planting in spring. Previous to planting a quantity of well-made manure, charred earth, and soot, was dug in. These plants have succeeded well, flowering more continuously than any other plant. Shortly after the first display of flowers, they ran rapidly to seed owing to the great drought. I clipped the *Viola cornuta* over with sheep shears, cutting off both seed-pods and flowers; the plants looked for some time rather bare, but the arrangement adopted, represented in the accompanying illustration of a 6-foot border, in a great measure prevented that defect being apparent.

1. Back row, *Ageratum*, lavender-coloured.
2. Vandykes of *Calceolaria* Yellow Gem (Downie & Laird's).
3. Vandykes of *Gazania* splendens.
4. Vandykes of *Viola cornuta*.

I have a bed or two in the flower garden planted wholly with *Viola cornuta*, but dotted with plants of Cloth of Gold *Pelargium*, and another bed with Mrs. Pollock. The *Viola cornuta* in these beds I treated in the same way as above stated, clipping it over, and they have been the gayest beds in the garden, and continued in perfect beauty up to the middle of October.

The vandyked border planted with *Calceolarias*, *Gazania*s, and *Viola cornuta*, is now (October 31st), still looking gay notwithstanding the frosts we have already had.

As a contrast I had a small circular-bed or two on grass in the flower garden planted with *Viola lutea*. This has done admirably, flowering continuously throughout the past hot summer. The treatment was the same as for the *Viola cornuta*; after the drought the extended branches were cut in a little here and there, and the seed-pods taken off. Since then, up to the present time, they have flowered continuously.—Wm. MELVILLE.

NOTES AND GLEANINGS.

It will be seen by our advertising columns that Mr. J. C. Stevens will sell by auction, on the 10th of December, the splendid New Golden Coleuses raised in the garden of the Royal Horticultural Society at Chiswick. These are of a class entirely different from those raised by the Society last year, and are, perhaps, the most lovely novelties in foliage at present existing. Some of the leaves are bright carmine, with beads of gold for an edging, while others are golden, with crimson shading and sanguine blotches; some are entirely golden, with dark red veins, and altogether they are so novel and so beautiful as to insure for them a wide range of popularity.

—We regret to record the death, on the 10th inst., of Mr. PRESTON, the able gardener at Victoria Park. He had been a short time from home, and on his return was attacked by typhus fever, which carried him off in a few days at the early age of thirty-five. He has left a wife and several children, and, we understand, quite unprovided for.

WORK FOR THE WEEK.

KITCHEN GARDEN.

Cape Broccoli and *Cauliflowers*, if there are any more of these, though only 3 or 4 inches round, turn them into a cold pit, placing the roots in some light rich soil. They will swell-off and come in very useful in the dead of winter, and some straw or other additional covering can always be thrown over them in severe weather. *Garlic* and *Shallots*, it is generally found that these thrive best when planted about this season. The ground should be well trenched, and a place chosen where none of the Onion tribe has been grown for some time. Many failures arise from planting them too deeply. They should merely be fixed on the surface and then sprinkled over with a mixture of soot, lime, and ashes. The smaller variety of *Shallot* is most prized by cooks generally; the large sort is more easily grown, and produces more abundantly, but the flavour

is by many considered not sufficiently strong. *Pears*, make a sowing of these and Broad Beans. Those sown now will be useful if the weather should be favourable, and though they be cut down by frost it will be only the loss of the seed. Sow upon wide ridges, so that the young plants may be defended from east and north winds. Cover the seeds with chopped straw, barley chaff, or sharp sand, as a protection from mice.

FRUIT GARDEN.

Proceed with pruning and nailing in all favourable weather, for if deferred until spring the work will be apt to interfere with other matters then demanding attention. If the trees were suitably attended to in the summer, there will not be many useless shoots to be removed now. Vines and Raspberries deprived previously of all unnecessary wood, had better have the shoots remaining left unshortened until the rigour of the winter shall have passed. Apples and Pears against walls should have their fruit-bearing wood spurs kept as close to the wall as possible, not only to secure the benefit of the wall, and prevent the unsightliness of long, overgrown spurs, but also to obtain fruit of good size and flavour. Attention to the short spurs produced on good, healthy trees when growing naturally as standards, will furnish a useful lesson on this subject. In the case of some of our best sorts of Pears, which have a tendency to form bold blossom-buds at the ends of short shoots of the present year's growth, care should be taken to retain a sufficient number of them, and, if long enough, to fasten them closely to the wall. Plum trees may be pruned much the same as Pear trees, but as the best fruit is generally produced on wood of two or three years' growth, care should be taken to lay in a little young wood every season. Those not much accustomed to nailing are apt either to use shreds too short, or too many of them. Trees, especially young ones, are often irreparably ruined by the former, and made to resemble rag shops by the latter. Comparatively few shreds will be necessary, if placed alternately, with a slight strain, upon the upper and lower sides of the shoot, and if the stronger ends are fastened with willows or rope yarn. However pretty it may be to see trees beautifully trained, the effecting that object by driving in nails close to the branch, or putting a strain upon it, endangering the bark, ought not to be allowed. Unfasten the young shoots of Peach, Nectarine, and Apricot trees, so far from the wall that they will incur no risk of being broken by boisterous winds, in order that the part previously reposing against the wall may be duly ripened before it is exposed to severe frost, and that active vegetation may be retarded to a later period in the spring. Where thin ties have been placed on part of the border next the wall for the radiating of heat, and keeping the border moist, they may be removed, to prevent them from being broken by frost, or the performance of the necessary operations, and if not considered too valuable, and if the draining is very defective, they might be bedded in clay, to throw the water off the border. In extreme cases, advantage might be taken of concreting the border. For those who are desirous of forming new plantations of the *Calceolarias* and *Calceolarias*, which should be done every six or seven years, young plants being found to produce more handsome fruit, and more plentifully than old ones, we would recommend from among the many varieties now cultivated the following—viz., Yellow Sulphur, good, and very early, but does not last long; Red Champagne, Taylor's Bright Venus, Primrose Green Gage, Red Warrington, Woodward's Whitesmith, Mellin's Crown Bob, Farrow's Roaring Lion; and, for preserving, the Small Rough Red. Of Currants, the Black Naples, Red and White Dutch, and Knight's Large Red. In light soils the above may now be planted with greater advantage than in spring. In preparing the ground, let it be trenched to the depth of about 2 feet, thoroughly mixing with the surface spit a liberal allowance of manure. About 5 feet may be considered a proper distance between the plants. Pruning Gooseberries and Currants may now also be proceeded with. Let the centres of the bushes be kept free and open, cutting clean off any strong shoots that rise from that part. Cut out all branches that cross each other, leaving the leading shoots about 10 inches apart, and topping at a bud inclining to the open space. All lateral twigs not required to form branches should be spurred in to a few buds. Black Currants require no pruning, except thinning out the branches a little when the bushes have become large and thick of wood.

GREENHOUSE AND CONSERVATORY.

If the plants are all clean, the work in the greenhouse is more routine. See that *Cape bulbs*, as we call the *Iridaceae*, are now well supplied with water, if their pots are full of roots.

The shoots of the different winter-growing *Tropæolums* will also require attention to training, otherwise they are very liable to become confused, if not broken altogether. *Tropæolum pentaphyllum* is hardly enough to stand outside without any protection. As soon as the *Chrysanthemums* begin to fade out them down, and protect the stools from frost. It is now time to prune all the young shoots of *Mandevilla suaveolens*, and you may strip off the remaining leaves, but the long slender branches had better be left on until spring. If it is closely pruned now, it may begin to grow too soon for any useful purpose, and stopping the young shoots does not answer well. *Ipomæa Learii* and *cicifolia*, should be pruned in the same way as soon as the leaves begin to turn yellow; the latter cannot be made to flower before the end of September when planted out in the border, therefore April is time enough to give the final pruning. The former, on the other hand, will flower by the middle or end of May, if closely pruned now; when pruned in February it flowers about midsummer, and if out in April, about a month later. Both these useful climbers succeed better in a large conservatory with a fixed roof, than in a stove or intermediate house. Passion-flowers, unless they are much crowded, need not be pruned or thinned till January. Few climbers repay one's care better than Passion-flowers, but they are often left so crowded as to completely destroy their native gracefulness.

TIPS.

This has been a dull, unfavourable month for forcing plants, and many things will be later than they were last season; but to make up for this, hardy plants, such as Lilies and Rhododendrons, are in better bud than usual. We have had no use for strong fires yet, and in this cloudy weather much less watering and syringing are necessary. It is a dangerous practice to force hard till after the end of December. 65° with fireheat is high enough for any useful purpose until that time. —W. KEANE.

DOINGS OF THE LAST WEEK.

In many respects, in planting, cleaning, washing, glazing, potting, gathering leaves, &c., the work has been chiefly a continuation of that of previous weeks. Other matters that have come under our consideration we will briefly allude to, without much arrangement, under different departments.

Digging in Winter.—This is chiefly useful in dressed grounds, and in very shallow soils, where it would be of little use going deeper than the good staple; but in all gardens where something is generally added in the way of manure, rotten weeds from the rubbish-heap, or charred material, the staple, however thin, will always become deeper, more especially if the bottom, however hard or unkind, be loosened every year, and at times a very little of it, whether of strong gravel or stiff clay, incorporated with the thin but more fertile surface soil. Bringing much of the subsoil up under such circumstances is a great mistake, but a sprinkling often does good, and loosening and leaving it, never fails to do so, as, ere long, the loosened subsoil will become like the good soil above it.

Trenching.—There are some gardens where this can be done to a depth of three spades, without encroaching more on the subsoil than just loosening and leaving it, and where such a practice can be followed, there will never be surplus or standing water, as the hard pan will be sufficiently broken. The soil of most gardens, except when made artificially, will not admit of trenching more than two spits deep, and loosening the bottom. The trenching can be more varied according to the depth of the soil, but the chief use of the operation in gardens, is to furnish to the young plants of a fresh crop, fresh soil in which to grow. All soils are ameliorated by exposure to the atmosphere, but in many cases, too, a soil that has become comparatively inert, from the surface being hard-cropped, will be greatly improved by a comparative rest at the bottom of the trench for a year or two. In trenching, as already alluded to, though moved, but little of the subsoil should be raised, and what is raised this year to mix with the other soil, would be all the better if well stirred in the bottom of the trench a year or two before.

In old-established gardens, the merely moving the top spit to the bottom, and bringing the lower portion of the soil up, will be all that is required, as a change of the layers of soil, and giving more depth for the roots, are the chief objects; but in trenching for the first time, and for particular purposes, it is often best to keep a good opening, and mix the various strata as the work proceeds. We are just doing away with a group of Rose beds, and forming another, and as, fortunately,

the position chosen is all turf, part unbroken for at least a score of years, and covering thus a virgin loam, and part which had been under cultivation only a few years ago, the mixing of the different soils will be all the better for the Roses, and they will grow more equally in strength, than if the different soils had been kept quite distinct. We intended to go down, where the beds were marked out, nearly 2 feet, and remove clay if necessary, but we dug to that depth, and loosened the bottom without meeting the clay. Knowing that the layer of clay was there above the chalk, we would have had some of it up, if our soil had been loose and sandy; but it is sufficiently loamy, without any admixture of clay.

When the object of trenching is chiefly to change the surface in loose sandy soils there is little necessity for breaking up the soil much when trenching, as the air will penetrate sufficiently without much pulverisation, and a flat surface, even if it becomes a little firm, will be as good as a looser one; but in trenching a stiff tenacious soil, the more broken and the looser and opener it is left the more will it be benefited by the frosty air of winter. In fact, in all such soils, unless when to be used at once for planting, &c., the trenching to change the surface soil should be turned into *ridging-up*, and as roughly and openly as possible, that the frost and the cold air may alike act in breaking and pulverising the soil. We have no doubt, though this is the best for loamy tenacious soils, that rough digging or flat-surface trenching are better for light lands, simply because they often need compression as much as stiff soils need lightening.

Such trifles may appear of little value to some of our greatly advanced cultivators, but we have seen lands not only subsoiled, but the subsoil raised and mixed with the staple to such an extent, that the field required years before it returned to the same fertile condition as it exhibited before the additional expense was incurred; and twice or thrice we have known ground deeply trenched in which nothing could be made to thrive until the barren subsoil was moved back to its original position, and the good soil, well rested, brought back to daylight again. Then the deep stirring did tell advantageously, but at what a loss of labour and time! The deep stirring, without bringing the barren subsoil to the surface, we always imagine—though it may merely be imagination—renders crops more independent of the seasons; for in a wet year the rains pass away more freely, and in a dry year the roots have more free access to the moisture stored up beneath them. Whenever practicable, chalk, lime, and sandy soil will ameliorate tenacious land, and stiff clayey loam will help to make light chalky and sandy soils more retentive of moisture. Lime in its quick state is most serviceable when there is plenty, or rather an excess, of organic material, vegetable or animal: hence the wondrous effects it often produces on peaty soils, rendering what was astringent and insoluble, soluble and sweet to the roots of plants. In very poor soils we would not use lime, except for the effects it would produce as a mere mechanical agent.

In all trenching by piecemeal it matters less, as stated above, how light lands are turned over; but it should be seen that in stiff lands the surface spit is not undermined and turned over in large unbroken pieces, for in such soil one of the uses of trenching is thus neutralised.

Manure.—As a general rule, when the manure of animals is applied for vegetable culture, it is best to have the manure covered up at once, and at such a depth as the young roots will be most benefited by it. In long-standing crops, as Asparagus, Globe Artichokes, Sea-kale, &c., it is well to mix some manure in the process of trenching and mixing the soil, and then add a little more on the surface when digging, preparatory to planting. For all deep tuberous roots, as Carrots, Parsnips, Beet, Salsafy, &c., the best plan is to have the bulk of the manure in the lower strata, or near the bottom of the trench, and the poorer and to some extent finer the top strata are, the finer and straighter will be the roots. Hence, often the difficulty of finding in old kitchen gardens soil fresh and poor enough for Carrots. When well stored with humus, or the remains of organised vegetable matter, to a good depth, the dressing with lime early in winter, and turning several times, will be attended with good effects. In such cases we have taken up crops in stiff soil, with the particles of chalk adhering to the fibres.

In preparing for fruit trees, by trenching or otherwise, unless the soil is very thin and poor, we would keep the manure near the surface, so as to encourage fruitfulness rather than too much growth, by keeping the roots more under atmospheric influences. Where quick growth of fruit or forest trees is the

object, then the manure may be well mixed with the soil. On talking over this matter with an enthusiastic amateur he instanced, in contravention of some of these statements, that some of our celebrated fruit-tree dealers actually had trenches taken out and liberally dunged for their fruit trees; and if the nurserymen found the system suited them so well, why should it not suit him and his purpose equally well? And so it would if he grew trees to sell. The nurseryman wants a good-looking saleable article in as little time as possible, and people will have fine-looking young wood, even if not the most thoroughly ripened. If the purchaser wish to have a large fine tree as soon as possible, by all means let him continue the high and rather deep manuring of the tree-raiser and seller; but if he want the tree thus purchased to fruit as soon as possible, and in rather limited room, then the chief manuring should be given near the surface.

It is not impossible by any means to combine both objects. Thus, we purchase a small tree that had been forced to grow luxuriantly by rich manuring; we wish it to attain a certain size as soon as possible, and after that to become fruitful. We then imitate the treatment of the fruit-tree raiser, and then when the tree is large enough we either root prune, or, in some cases, carefully raise it and replant, which gives such a check to mere growth, that surface manuring will be sufficient for a long time afterwards to maintain the fertility of the tree, and just enough of growth to keep the tree healthy. Once obtain a good crop from such trees, and, as stated lately, there will generally be little necessity for root pruning, or, indeed, pruning of any kind, for a full crop is a great equaliser of strength. A tree thus made fruitful, has a natural tendency to continue so, if the help given by manure is applied at the surface. What we mean by "equaliser of strength," is, that so far as productiveness is concerned, roots and fruit-buds are brought more into harmony. Excess of fertility would too much diminish necessary vigour; but this can be helped in two ways, thinning the fruit, and surface manuring.

Condition of Manure when Applied.—This has been passively alluded to. In much of the manure that comes to the garden, there can be little question as to its application. Rotten and half-rotten hotbed dung is always ready to be applied in any way, and so are the droppings of all kinds of animals, as horses, cows, rabbits, &c., which can often be procured with but little litter mixed up with it, from the metropolis and large towns. This may be used at once, but more sparingly in proportion to its newness. For tender things, when mixed with the soil, as for pot plants, such droppings should heat, and be spread out and dried before using them, as then at a little loss of nourishing matter they will be sweeter. All stable and cow-dung, &c., that comes to us with a good proportion of straw or litter, is generally the better of undergoing a process of fermentation. Some of the nutritive gases will thus be lost, but we gain in compactness for carriage, and the celerity with which such manure acts on the plants cultivated. When the manure is intended to act chiefly as a mechanical agent, as in stiff land, we would not let the fermentation and decomposition proceed far before using it, and would place it in the soil as soon as possible. For rank feeders, such as Turnips, we would have the heap farther decomposed, so as to be moist, and short, and would turn it beneath the soil as soon as possible. We often see huge fields covered with little heaps for days, and even weeks, before the dung is ploughed in, and such manure, good it may be at first, is thus by a process akin to haymaking, rendered little better for the purpose contemplated than so much dry litter. As stated above, we are well aware that in thus decomposing a heap of manure, we lose valuable properties, but this may be counteracted by spreading a thin layer of soil over the heap when in a state of fermentation. It is very easy to allow such a heap to ferment too long, which it will have done generally when it can be pitched into a cart with a spade or shovel, instead of a steel fork. When used in a fresh, unfermented state, it should be placed deeply in the soil, and though such manure will act slowly, it will continue longer to exercise an influence. The question of carriage, by cart or barrow, is often a serious one, and so far as that is concerned, and also so far as quick results are calculated on, it is well to use littery manure partly fermented and decomposed. Hotbeds made of such material, when they remain from eight to ten months, are generally too far reduced to contain all their best properties as manure, though very useful in gardens; but much farmyard manure might be used as temporary hotbeds, and then be none the worse for the farm.—R. F.

TRADE CATALOGUES RECEIVED.

James Smith, Darley Dale Nurseries, near Matlock, Derbyshire.—*Wholesale Catalogue of Trees, Shrubs, &c.*

F. & A. Dickson & Sons, 106, Eastgate Street, and Upton Nurseries, Chester.—*Catalogue of Forest Trees, Hardy and Ornamental Trees, &c.*

COVENT GARDEN MARKET.—NOVEMBER 18.

Our market has been very dull during the past week, and prices have a downward tendency, probably owing to the excitement of the elections, the wholesale trade being especially quiet. Peas are good, and comprise Winter Nellis, Glou Morcean, Chaumontel, and Beurre d'Esp.

TO CORRESPONDENTS.

.. We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely* to *The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

STACHYS LANATA.—"If 'F. J.' wishes to have a stock of Stachys lanata for next spring, I will forward him a few scores of very large plants that will break up into hundreds for spring and summer gardening.—NEMO Potter's Bar Post Office, Herts."

ROSES FOR EXHIBITION (J. C. Mackay, Kilbarney).—Your questions were answered October 19th, page 336. We conclude you mean Medlars; we never heard before of "Medlards."

ROSES BEHIND THIS YEAR (A Lady, Somersetshire).—"Do not move any of the dormant buds now. If they are shooting, or threatening, perhaps it would be best to take the plants up, shake out the soil, and put them back again. Litter or straw, placed so as not to exclude air, will be a good protection to the buds. The Manetti stock should not be cut back in spring till the buds show a disposition to start. The beginning of March is the usual time. Be guided by the weather.—W. F. RADCLIFFE." (J. H.).—"The best thing to do with your Manetti Rose buds is to fasten straw over them, but not so as to exclude air.—W. F. RADCLIFFE."

LUMINOUS INSECT (Observer).—That which you noticed was of the species we named in our last number.

FRUIT-GARDEN ARRANGING (T. T.).—We do not think your ground could be better arranged for a fruit garden than it now is, the walks being well disposed for affording ready access to every part. We have no fault to find, only we should have liked the walks better had they been wider, for the sake of appearance; but in so small a space we consider them sufficient, and as they exist we would not alter them. The whole of the trees which you do not consider worth saving should be cleared out, and those which you wish to retain we would take up and lay in, entirely

clearing the ground of everything. Ascertain whether water does or does not exist in the subsoil, and if it does the ground must be properly drained by the drains 21 feet apart, running lengthwise of the garden. Put one drain in each of the borders numbered 1 and 3, and then divide the distance between them, so as to have one in the centre bed. They should not be less than 3 feet, nor more than 4 feet deep, and must have a proper fall and outlet. The whole of the ground should be trenched not less than 26 inches deep, but better to the depth of 2 feet, even if some of the clay be brought to the surface. The surface soil should be placed at the bottom, and the bottom brought to the top. If the ground is poor a good dressing of manure may be given, and worked in in the trenching. The ground will then be fit for planting. No 1 wall, or the wall of No. 1 border, we would devote to Peach, Nectarine, Apricot, Plum, and Pear trees, the last on the Quince stock, all for vertical cordons, as you wish for that mode, though we should prefer them oblique trained. As they are to be planted 2 feet apart, you will have space for forty-one trees, and all should be maidens, which you may obtain retail at a moderate price. We cannot name any grower in particular, but the principal nurserymen advertising in our columns would serve you well. Of the forty-one trees we would have eighteen Peach and Nectarine trees—namely, twelve Peaches and six Nectarines. Of Peaches we would have three Early York, three Grosse Mignonne, three Bellegarde, two Barrington, one Late Admirable; of Nectarines, two Elruge, two Rivers's Orange, two Violette d'Étiève; of Apricots we would have three Henslerk, three Kuisba, two Bauge; Plums, two July Green Gage, two Kirke's, two Jefferson, two Cox's Golden Drop; Pears on the Quince stock, one Citron des Carmes, two Marie Louise (should be double worked), two Winter Nellis, one Forrele, one Glon Moreaux. The Peach, Nectarine, and Apricot trees ought to be planted at the end next the flower garden, commencing with the Apricots, so as to have them together, the more readily to protect the blossom and young fruit. One foot from the wall on border No. 1, plant Apples on the English Paradise stock at 6 feet apart for lateral cordons (for kinds see page 349), and No. 4 border we would plant with Apples for vertical cordons 2 feet apart, and have two rows, one at 1 foot from the wall, and another at the back. The lateral cordons at 1 foot from the wall, and the vertical cordons dessert kinds. The trees on No. 4 should not reach to within the wall of No. 1 border by the distance the vertical cordons are to be in height, which in your case should not exceed 6 feet. We would extend the lateral cordons all round the garden on the borders No. 2 and No. 3, and have them Apples, but they will do little good in No. 3 unless the trees shading it are cropped. The wall of No. 2 border we would devote to Pears on the Quince stock, as vertical cordons 2 feet apart, sixteen trees: four Bergamotte d'Espéran, three Beurre Superfin, three Louise Bonne of Jersey, three Prince Albert, two Baronne de Mello, and two Beurre d'Étiève. No 3 wall will only suit Currants—Red, White, and Black. The best sorts are the Red Dutch and the Long-bunched Red, which is a little latter, and Transparent White—these should be planted 2 feet apart; and the Black Naples 3 feet apart. You may have the Morelle Cherry on the Mahaleb, as well as the Currants, on the wall of No. 3, placing the trees 6 feet apart, and training them in the fan form. We now come to the centre bed, and this we would plant with a line of Pears on the Quince stock, Cherries on the Mahaleb, and Plums as pyramids, all 4 feet apart, and 3 feet from the wall, needing twenty-eight trees for the sides, and four for the ends, or thirty-two in all. The four at the ends may be two Doyenne d'Étiève, two Pears on the Quince stock, four Fondante d'Antoine, four Colmar d'Étiève, four Williams' Bon Chrétien, four Beurre d'Arenberg, and two Zéphirin Grogioire. If you prefer Apples in place of Pears, they succeed admirably as pyramids on the English Paradise stock. Of Plums you may have two Reine Claude de Bay, two Kirke's, two Guthrie's Late Green, and two J. G. Brown. All round this border, 1 foot 3 inches from the wall, and also in the inside 1 foot 9 inches from the trees, you may have a row of Strawberries, and the space between the Strawberries or the pyramids you may dispose of by having a rail up the centre for Raspberries, Red Antwerp or Pastoff, and have a row of Gooseberries on each side, but you must in the case of two rows of Gooseberries omit in a year or two the two inner rows of Strawberries. Perhaps it would be as well only to have Raspberries one-third the length of the central border, two rows, and have two rows of Gooseberries 3 feet apart at the other end, they being 5 feet from the row of Pyramids. If this arrangement of the central bed did not give you enough of space for Strawberries, Gooseberries, and Raspberries as you wish, you might have a bed of Strawberries all round 4 feet wide, a row of Raspberries up the centre, and a row of Gooseberries on each side. This would be a good arrangement, and may probably suit you better than the other, if you have enough Pears, &c. in the other compartments.

PLATYLOMA FLEXUOSUM (A. M. G.).—We should think it a desirable plant for either a basket or a peat wall. We should, if we could not give it a pot, prefer the basket, but it is not suitable for suspending.

TIME OF REPOTTING AZALEAS (Cantab.).—The best time for repotting Azaleas is after flowering, or when they are commencing to make fresh growth. They may also be potted after the growth is complete.

RHODODENDRONS FOR A TOWN GARDEN (A Lover of Roses).—The good kinds are Everlastingly, rosy blue; Blandynum, rosy crimson; and Lefevreum, purple crimson.

STOCKS FOR ROSES (J. P.).—Gloire de Dijon succeed well on the Briar, also on the Mame. Jules Margottin would be best on the Manetti, though if your soil be strong they would both do well on the Briar.

CUTTINGS OF ACACIA, GENISTA, AND CAMELLIA (J. C. L.).—The best time to put in cuttings of the former two is early in summer, taking the growing points after the leaves have become firm, or when the wood is about half ripe. They should be inserted in sandy peat, surfacing the pots with sand. They should be covered with a bell-glass, and placed in a gentle heat and shaded from bright sun. Camellias are not worth propagating from cuttings. They are best grafted. The stocks, however, are raised from cuttings extensively, July and August being the best season, when the shoots become ripe at their bases. They require a bottom heat of from 70 to 75°, and sandy peat and loam, with sand in equal parts, surfacing the cutting pots with about half an inch of silver sand.

PLACING MANURE ON A VINE BORDER (J. H.).—You may cover the border with littery manure, but we do not see the necessity for forking some into the border previously, though the surface may be lightly stirred before placing the manure on the border. Your flower is a Pelargonium, but we cannot name florists' flowers.

RHODODENDRONS AFTER FORCING (West of Scotland).—You did right to keep them under glass until the growth was completed, also in placing them out of doors afterwards, the pots being plunged in coal ashes in an open situation, and plentifully supplied with water in dry weather. In this position we would leave them another year, top-dressing the pots with cow dung in March, and at the end of May watering well in dry weather. We think your plants will form bloom buds plentifully next season. They do not generally flower the year after forcing. You are wrongly advised to keep them under glass constantly with similar treatment to Azalea indica, though if you have a cool, airy, light house and plenty of room, that plan answers very well, and is desirable for some kinds, but not for those you name.

LAWN DISFIGURED BY BEING TRAMPLED (E. G.).—We should advise you to well scratch the lawn with an iron rake in March, and then spread over it some well-rotted manure or fine rich compost. Early in April give another good raking, clearing off the rough of the manure or rich compost, and sow over it Festuca duriuscula, 4 lbs.; Festuca tenuifolia, 4 lbs.; Cynosurus cristatus, 6 lbs.; Poa nemoralis, 2 lbs.; Trifolium maris, 4 lbs.; Trifolium repens, 4 lbs.; the above in mixture for one acre of lawn. Roll well after sowing, which should be done when the ground is dry, but with an early prospect of rain, and do not mow for a month, or better six weeks, then mow as usual and keep well rolled. Bonedust is the most durable of manures, excellent for grass. It may be applied in March, before the first raking of the lawn, distributing it broadcast over the surface, and at the rate of 12 lbs. per 30 square yards, which is a moderate dressing.

PARAFFIN OIL ON BUDS OF PETIT TREES (J. Q.).—We have seen it applied to every part of the trees indiscriminately, and have not noticed any injurious effect, but it is not in our opinion a desirable proceeding, especially as there are other more safe, less nauseous, and pleasanter substances which may be applied, and will answer the purpose. Clarke's Compound will destroy the scale, and every part may be coated with it without danger of injury to the buds or even leaves. Two ounces to the gallon will kill scale, but for winter dressings we should use it at the rate of 8 ozs. to the gallon. However, we do not think paraffin oil would injure the buds any more than the wood if applied to them, as it ought to be, at this season. If the application be deferred until the buds begin to swell, we should not advise it nor of any other composition. Now is the time for dressing fruit trees and up to February.

SELECTION OF PLANTS (S. D.).—Stone Plants: Allamanda grandiflora A. Hendersoni; Clerodendron Edmondi; C. Komppii; Cyrtocarpus reflexus; Dipladenia amabilis; D. crassifolia magnifica; D. splendens; Hoya nerioides; Ixora acuminata; I. coccinea superba; I. crocata; I. javanica; Loribunda; Rondeletia speciosa major; Stephanotis floribunda; Vines: rosea; Combretum purpureum; Pteroma Benthianum. Greenhouse Plants: Aeschynanthus venosus, Phorocoma prolifica; Bernesei; Aphelandra macrantha purpurea; A. humilis; Boronia serrulata; Bragmilia gracilis; Chorozema coccinea splendens; Croton elagnia major; C. macrantha; Dracophyllum gracile; Eriostemon intermedium; Gecythis tulipifera; Kolosanthus coccinea superba; Leschenaultia formosa coccinea; L. splendens; Pteroma elegans; Pincella B. Andersoni; and Rhyncospermum jasmoides; Adiantum falcifolium; A. pentadactylon; A. tripteris; Asplenium Velebannum; A. caudatum; A. premorsum; Blechnum corceadense; Chloranthus hirta var. Ellisiana; Davallia polyantha; Dryas muscicola; D. quercifolia; Gonolophium subacuticatum; Gymnomorpha parvifolia argyrophylla; G. Luncheon; Neottiopteris nidus; Notholaena trichomanoides; Pteris tricolor; and Platycodon stemmatis. The above collection does not include trees and Filix Ferus. Lycopodium: Selaginella africana, eresia, atrorubens, circinale, umbrosa, lepidophylla; Lycopodium Wallichii, decussatum, serpens, emblema, Martensii variegata, and Griffithii.

FLOWER BORDER (Norfolk).—We could not improve your proposed arrangement, only the plan would be better on gravel, but grass will do.

WANTED VINE LEAVES (J. P.).—We do not consider the wants on the Vine leaves a disease. When the roots have less moisture and the atmosphere of the house is a little drier, and the Vines are scarcely so vigorous in growth, the A. will disappear.

GOLD AND BRONZE PELARGONIUMS.—Mr. Cabell says, "Your correspondent W. B. G. speaks very positively that Perilla is a green variety; but I have some dozens of that anti Kentish Hero side by side, and both are now presenting a beautiful gold bronze appearance, and judging from the present condition I really could not say which of the two is the more attractive; but knowing their good as well as their bad qualities, I freely admit, as I did in my former letter, that Perilla is much behind Kentish Hero for bedding purposes."

ORCHARD HOUSE FRUIT TREES (W. Nolan).—With such a mixture in your orchard house, you will only succeed by keeping one end (either by giving less air, protection, or other means), warmer than the other; and beginning at the warmer end we would thus arrange them—Oranges, Lemons, Figs, Vines, Peaches, Nectarines, Plums, Cherries, and Apricots.

CUCUMBER LEAVES INJURED (Seaside).—The spots and wrinkles on the Cucumber leaves are chiefly the result of the sun striking on the leaves whilst there is an accumulation of vapour in the house. Early air-giving will prevent this, and a slightly drier atmosphere. We could see no thrips, but we almost think these little insects have been there. Examine the lower side of the larger discoloured leaves, and if the insects are there they will soon jump off. We have caught them on a wet sponge, but on a large scale the best remedy is smoking with tobacco.

CHRYSANTHEMUMS LOSING THEIR LEAVES (J. G. H.).—Chrysanthemums require much moisture, and everytime a pot plant becomes dry it revenges itself by throwing off some of the lower leaves. A sudden change will also cause this, and sometimes it results from the plants standing too thickly.

TREATMENT OF COLD STIFF SOIL (Idem).—Our mode of treatment would be to dig or trench now as deeply as the good soil, loosen the bottom with a pick and leave it, and as the work goes on leave the soil in rough ridges to allow the air to go freely through it. After it has been well exposed to frost turn the ridges over, and several times, and then in spring apply the manure, so that it shall not be wasted before the roots reach it.

FLUE HEATING A GREENHOUSE (Burgley).—We do not quite understand the mode you propose, as your end section merely shows the flue crossing the house at the end. If you mean to take a flue under your

pathway and then across the end, you will have more than heat enough in such a house, and for that matter, a flue across the house at one end will keep out frost, but it will always be hot at that end. From your section we see a stage at back and a platform in front, and pathway between them. If the chimney must necessarily be at that end, we would take a narrow flue and return it under the pathway—say, 5 inches wide, inside measure, and the same depth, or 5 inches deep. Three rows of bricks thus make your double flue, and if these are covered with thin tiles well plastered, and then with paving tiles, you will have a good inconspicuous flue. We have no faith in covering a flue with sand; according to the quantity and the dryness it will prevent heat radiating freely. Flues rarely crack if kept clean and sweet, and if the stoker shows some judgment.

SPAWNING MUSHROOM BEDS (D. B.).—If the bed, as you say, has declined gradually to 75° from 180°, spawn as soon as possible, and heat the bed firm. If the bed should still decline in heat, add 2 inches in thickness of good fresh droppings before putting on the soil. See a late number for details of management.

WINTERING CALADIUMS (Idem).—The Caladiums will keep very well in your warm stove-hole, if it is seldom below 60°, and the pots may stand upright packed and covered with moss, which will prevent the soil becoming too dry. As soon as the Caladiums show the least signs of moving report them in fresh soil, and place them where they will have light as well as heat. The soil, even now, should not be dust dry.

FORCING BLACK HAMBURG VINES (J. C.).—Vines from which the fruit was all cut in September, and the wood now well ripened, will need no fire before starting them in March, on ordinary occasions, but if we had a frost nearly to zero, we would put a little fire on. The outside border will be the better of a little litter, but to force at that time there is no necessity for keeping out all the rain, but the roots will be more under command.

INSECT-TANK HEATING (A Constant Reader, Torquay).—The common centipede, *Julus crassipes*, is what is so common among the soil of the Cucumber beds. It delights chiefly in half-decayed vegetable and animal matter. So long as the roots of the Cucumbers are healthy, they will be little interfered with. We have found them in Cucumber stems when there was any crack, or the least signs of decay. A few times we have had healthy roots cut through by them. Altogether we would sooner be without them than have them, and we have used half-rotten cabbage stalks and stems of beans, and pieces of carrots showing traces of decay, to entice them, as well as bits of half-rotten Apples and Pears, and generally succeeded in thinning them by examining such baits. We do not think the damping-off of the leaves is to be traced to the doings of the centipedes, but would rather attribute that to want of air and want of sufficient heat. For such a contemplated Cucumber house with beds on each side, you will require tanks on each side, or two 4-inch pipes for bottom heat, and not less than two 4-inch pipes on each side for top heat, if you contemplate having winter or early Cucumbers.

ARBOR-VITÆ SEED (C. B. R.).—Your seed, if not abortive, as it very often is, will be easily disposed of. We do not know the value. Write to the wholesale seedsmen who advertise in THE JOURNAL OF HORTICULTURE, enclosing sample of seed.

WINTER GREENS BELIGHTED (Idem).—From your description we should think your Greens are infested with the Cabbage plant louse (*Apbis brassicae*). Dust them alternately with soot and fresh-slacked lime, or you may syringe them with a solution 1½ oz. to the gallon of Clarke's Insect-destroying Compound, which will free the plants of the vermin.

PERENNIALS FOR CUT FLOWERS (J. R.).—*Alyssum saxatile compactum*, *Anemone paniculata*, *Anemonea cruenta*, *Antirrhinum*, *Aquilegia*, *Aubrietia deltoidea grandifolia*, *Aster tataricus*, *Asclepias tuberosa*, *Campanula aggregata*, *C. carpatia*, *C. speciosa*, *Cheiranthus variegata*, *Conwallia majalis* varieties, *Daphne genkwa*, *Delphinium alpestris*, *D. belladonna*, *D. formosum*, *Diarrhiza floribunda*, *D. fragrans*,

Pinks, *Carnations*, *Picotees*, *Dielytra spectabilis*, *Erigeron speciosus*, *Hebeboris niger*, *Hepatica* var., *Snowdrop*, *Winter Aconite*, *Hyacinthus* var., *Hypericum elycaium*, *Lathyrus grandiflorus*, and its variety *Friedrich*, *L. latifolius* and varieties *alba*, *pallidus*, and *splendens*; *Lilium auratum*, *aurantiacum*, *Brownii*, *oleaceum*, *candidum*, *lanceolatum*, and *temulatum*; *Lobelia fulgens* St. Clair, *Lychnis Haageana*, *L. viscaria* *splendens*, *Muscari botryoides*, *Myosotis arctica*, *M. palustris*, *M. sylvatica*, *Narcissus* var., *Paeonia* var., *Phlox* var., *Polygonum vacinifolium*, *Pyrethrum* var., *Sedum grandiflorum*, *Schizostylis coccinea*, *Scilla anemone*, *S. bifolia*, *S. sibirica*, *Spiraea filipendula plena*, *Statice latifolia*, *S. tatarica*, *Stipa pennata*, *Triton* *Burchelli*, *T. naria* and var. *glaucescens*, *Trollius europaeus*, *Veronica tenerum*, *V. taurica*, *Viola villosa*, *Viola odorata*, var. *stricta*, *suavis*, and *calcarata*.

FUEL FOR HAY'S CONSTANT STOVE.—"D. Deal," wishes to know if this is to be had in London, and if so, where? Catalogues for "D. Deal," must now be sent to him at Westwell Vicarage, Ashford, Kent.

PLANTING BRIARS (S. M.).—If we understand you aright, your wish is to form a screen, and of Roses; but you propose to plant stocks and bud them next year. For a screen the plants should not be more than a foot apart, and if you plant Briars they must be headed or cut down to the height you wish them. The Briar's delight in a strong loam, and you cannot manure too highly. We would not plant Briar but Manetti stocks, and bud them close to or a little below the soil. The plants would, of course, be dwarfs, and the Manetti would be more suitable for your soil than the Briar. Dahlias should be planted 4 feet from the Roses, and that distance from plant to plant.

TRANSPLANTING SWEET WILLIAMS, WALLFLOWERS, AND STOCKS (Idem).—You may prick-off in a sheltered situation the Stocks, and plant out where they are to remain for flowering the Sweet Williams and Wallflowers, moving each with as much soil as possible.

ORANGE TREE LEAVES SPOTTED (X. Y.).—The leaves sent are spotted we think by drip, or water falling on them from the roof; but whether the drip be caused by imperfect glazing, or condensation of the moisture of the internal atmosphere, we are not in a position to state. The spots would also be caused by allowing water to remain long on the leaves at this season. What are the white specks on the upper surface of the leaves? Are they not the result of the recent painting of the house? If the drip be from a recently-painted house we should attribute the spotting to that, and you must give air so as to keep down drip from condensation. The tree from which the leaves are taken is infested with the Orange-tree Coccus or scale, there being more than one of these insects on the under side of the leaves sent to us.

TRENTHAM BLACK GRAPE (Reader).—In constitution and stamina the Trentham Black Vine is very robust and vigorous, it shows fruit freely, but requires a more than usual amount of heat to set the berries perfectly—about the same amount as the Muscat of Alexandria. The fruit if well ripened will hang well, but ordinarily the skin is apt to crack just at the insertion of the stalk, and specially decay the bunches thereby becoming thinned gradually, a berry at a time. It is not a good-keeping Grape, not equal to the Black Hamburgh. In flavour it is superb.

NAMES OF INSECTS (F. Manning).—The insect on your Peach-tree leaves is the red spider, *Acarus telluricus*. The vapour of sulphur, not from burning sulphur, is fatal to this insect. Heat the hot-water pipes of the houses, or having hot-water pipes filled with boiling water, sprinkle upon them flowers of sulphur, which begin to vaporise at a heat of 170°, and then shut up the houses or frames.

NAMES OF PLANTS (J. R. W.).—*Cornus mascula* or Cornal Cherry. (*J. W.*)—*Asplenium fruticosum*. (*Tertio*)—1, *Blechnum brasiliense*, slightly different forms; 2, *Seprodium molle*; 3, *Pteris arata*; 4, *Gymnogramma tartarea*; 5, *Woodwardia radicans*; 6, *Adiantum tenerum*; 7, *Tox* young for determination. (*B. R.*)—A *Seprodium*, apparently, near to *S. arbusculum*. (*S. R.*)—A variety of *Asplenium Filix-mas*. (*P. P.*)—We do not recognise the leaf sent.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the week ending November 17th.

DATE.	BAROMETER.		THERMOMETER.				Wind.	Rain in inches.	GENERAL REMARKS.
			Air.		Earth.				
	Max.	Min.	Max.	Min.	1 ft. dp.	2 ft. dp.			
Wed... 11	30.193	30.028	45	39	45	44	N.E.	.03	Hazy; overcast, mild air; clear and fine at night.
Thurs. 12	30.154	30.235	47	37	45	43	N.E.	.09	Cloudy, overcast; very fine; clear and fine.
Fri... 13	30.147	30.290	45	35	45	43	N.	.09	Overcast; densely overcast; very fine at night.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

POULTRY SHOW DETAILS—JUDGES.

Among the "many things" to be considered at the meeting to be held pursuant to the proposal of your correspondent "J. WALKER," allow me to direct attention to that of the appointment of judges. The committees of some of the late shows seem to have supposed that any gentleman who had held office as secretary to a show must perforce have had conferred on him the ability to act in the capacity of judge. I am desirous to inquire if the meeting will not resolve to ask the managers of each exhibition if they are not prepared to go a

step further, and in future have the prizes distributed by lottery?—X.

AN OUTRAGEOUS CASE.

We had a week or two ago a very excellent show held not far from Liverpool in which the secretary was a "very successful exhibitor," I was also an exhibitor, and, of course, patronised it, and you may judge of my astonishment when I found that the Secretary had entered in his own name forty-one pens, and nine others in the name of a member of his family, and the prizes awarded him were as follow:—Cups, 2; first-prizes 11; second prizes 12; and commended pens 13, the total money value of which, including the cups, amounts to £35 7s.

Do you think exhibitors could feel satisfied? I can assure you they were not, and many were the complaints I heard, and if I may judge from the conversation I had with some parties, next year's show will prove a failure if such is again to be the case.

My own opinion is that a secretary has no right to show anything whatever, and if he does so it is doing an act of injustice to exhibitors generally. He is supposed to know to whom the birds belong, and in fact to have a knowledge of everything connected with the show.

I should like to hear the opinion of some of the readers of "our Journal" upon the subject. I think the majority of them would object to support a show if they knew the secretary would be the principal exhibitor, at any rate if such is to be the case another year they will not receive the support of—A CHESHIRE MAN.

[We partake your feelings and think such exhibiting should not be allowed. It would destroy any show in the United Kingdom if such things were permitted.—Eps.]

BREEDING PILE OR PIED GAME FOWLS.

In breeding Piles, or Pies, the golden rule that "like will best produce like," should be attended to, and the best and quickest Piles are produced by breeding "good Piles with good Piles" of different strains, and of first-rate blood, so as to make a first-cross of the Pile colour. The brood hens should be all sisters and of one strain, and the brood cock of a different strain and no relation to the hens in blood, but equally good, and matching them in perfect shape and colour. If "breeding in-and-in," put the best old cock to the best two-year-old hens; two, four, or six hens at most to one cock—two hens do best—and the chicks should be hatched in the last ten days in March, or in April or May. If crossing from different strains breed from a two-year-old cock and hens, as then in their prime. A two-year-old cock to the best old hens is also good in breeding in-and-in, but the first plan is, perhaps, the best. Red or bright red eyes are essential to obtain fine-coloured Red Piles, as the red eye gives a redder feather; the white-legged strains are hardest, keenest, and gamest, and do not run so large or heavy in flesh as others. Piles to be handsome should be neither too light nor at all dark in colour, the bright red-coloured birds being the best and handsest.

The Chestnut, Ginger, Orange, Lemon, Yellow, Gravel, and Dark Piles possess less beauty than the bright red Blood Piles do, though some admire Orange Piles. Dark Blood Piles are also less beautiful than the bright red Blood Piles. The old Black-marked Worcestershire Piles are also inferior as to colour. Yellow or daw-eyed Piles are inferior, but yellow-legged, red-eyed Piles are good birds and the handsomest Piles of all, if of a good red colour. Willow-legged Piles are handsome also, if red-eyed, as they generally are.

Piles were originally produced from the red-faced Red-breasted Ginger Reds (not Ginger Brown Reds), and the Black-breasted Reds; also, of course, from Whites, and some came from the Red Duns and Ginger Blues.

Piles, or Pies, as their name denotes, should be pied or slightly pied nearly all over, and such as these are the quickest Piles and most lively.

The exhibition "whole-coloured" Piles are merely "White-breasted Reds," and might be more correctly so termed than called Piles, and such, though very handsome in colour, are slower birds than the true Pies. Piles, however, should not be spangled, or spotted, or the markings approach the "spangles."

The usual way of making Piles is to put the White hens with yellow legs to willow-legged Black-breasted Red cocks. This keeps the Pile red colour from becoming too faint or too pale, but it makes rather slow Piles. The White cock put to Partridge hens makes more Piles than the above way, which makes most Reds, and the White cock makes rather a quicker Pile than the Black-breasted Red cock does. If Marble-breasted Piles are wanted, I should prefer making them from the Red-breasted Ginger Reds (not Ginger Brown Reds), which make quicker birds than the Black-breasted Reds do, and also harder and gamer. If good White-breasted Piles are wanted, I prefer breeding them from good red-eyed Red Duns with white or yellow legs, but never from the Smoky Red Duns, which would spoil the clear colour, but from the clear-coloured Blood-red Duns, and such Red Duns will, if really good, make a better Pile in my opinion than our heavy willow-legged, exhibition, Black-breasted Reds do.

Marble-breasted Piles are harder in breast and feather and gamer than White-breasted Piles are, and are faster Piles, and truer Piles. A breed of Red-breasted Ginger Reds, yellow legs and red eyes, makes the best Marble-breasted Piles I know of, crossed with white-legged red-eyed Pile or White hens. Good Red Duns also breed excellent Piles, and I heard that at the last Ashford Exhibition, in Kent, a Captain Lambert showed some excellent "Dun Piles." In breeding Piles with Piles, you preserve that quickness for which Piles have always been celebrated, and which the Black-breasted Red or Duckwing-cross does not always maintain. Slow Piles are poor Game fowls. The only fear in breeding Piles with Piles is, that the red colour should become too pale or faint, and the white colour gain too much. Most of our exhibition Piles have, I think, been bred from the old white-legged Pile hens, put to willow-legged Black-breasted Red cocks, which will give white, yellow, and willow legs.

Many Piles have been bred from Brown Reds and Ginger Brown Reds. These are generally "Gravel" Piles and browner in colour, and not very handsome-coloured, being often too dark in face, with dark nails, and a dark-stained white leg, but are game birds. Red feathers in the tail, I think, show goodness in Piles. Piles are remarkably prolific, but the hens want to sit more frequently than most Game hens, and both hen and cock chickens are more quarrelsome than in most Game breeds, Brown Reds being in general the next most quarrelsome. Pile hens generally lay better than either Brown Red or Duckwing hens. Piles, Ginger Reds, Gingers, and Whites are the liveliest and quickest colours of Game fowls, as are some Red Duns, Blue Duns, Birchen Duns, and Birchen Reds, and these colours never incline to "run to flesh" so much as Black-breasted Reds, Duckwings, and Blacks often do, these three sorts gathering more flesh in general than other colours, especially when inclined to be large.

Ten or eleven, or even nine, eggs are quite sufficient for most Pile hens to sit on, for they are rather scant in feather.

Piles seem to have been first brought much into notice in Chester and its neighbourhood, and were then mostly white-legged birds. I have heard the Lemon Piles were bred from Yellow Duckwings and the Derby Reds, also from Yellow Birchens, Ginger Blues, and Blue Duns (yellow necks). The true Lemon Pile has yellow legs and yellow or daw eyes.

No two colours cross or mix better than clear Red Duns and Piles do, and no cross is less trouble in making, or less liable to fail in colour than this cross, which makes both Piles and Red Duns good quick birds.

I am aware that my taste in making and breeding Piles may appear rather singular to our modern exhibition breeders, to such more especially as will always make their Piles from Black-breasted Reds, which is the more common method. I always look chiefly to great liveliness in really good Piles. I also look for a light hard flesh, activity, and a very scant feather in first-rate Piles, which should never be heavy, fleshy, large birds, and to obtain such I like to breed a little out of the ordinary method.

In crossing Piles with Red Duns, the Dun cross will take out all tendency to a brown tinge in the feather or to red feather in the Piles. The dun colour will also in crossing with Piles if too dark, cloud a little the breasts of the Piles so made. The Orange Dun Piles are, by some breeders, thought to be the handsomest Piles of all.

Piles do not fatten at all well for table, nor will they pen well at all, either for fattening or for exhibition, as they "fret" in the pen too much, and shed their feathers when penned more than almost any other Game fowls.

Our exhibition Red Piles with yellow legs and red eyes, are our handsomest Piles, and all must allow these to be as beautiful Piles as can well be produced, though the white-legged are harder and gamer. Breeders wishing both to exhibit and to have good layers, cannot do better than breed Piles and Black-breasted Reds, as birds of these colours will prove better egg-producers than either Brown Reds or Duckwings. Piles and the Black-breasted Reds should, however, be bred separately, or the Piles will give the Reds too much white, which will show itself in the wings and tails of the Black-breasted Reds, and spoil them for exhibition birds.

In remarking on the laying qualities of Duckwings and Brown Reds, I should state that Yellow Duckwings lay very well, but not so the Grey Duckwings in general, and that some of the strains of the Brown Reds also lay very well. Piles, however, lay better than either of them.

I omitted to state in my last paper on breeding Duckwing

Game fowls, that if the very hardest and gamest Duckwing Greys are required, they can be best produced from a dark willow-legged Grey Duckwing cock put to black-legged Dark Grey hens, also in less numbers from a Dark Grey cock put to Duckwing hens. Duckwings thus produced will not, however, be perfect in colour, and for exhibition I do not recommend such a cross, as "Duckwings with Duckwings" breed more perfect and correct-coloured birds as a matter of course. Dark Birehens crossed with Duckwings will also produce good Birehen Duckwings. I wish also to state that many of our present Piles were produced from the white-legged Pile cocks put to willow-legged Partridge hens, as well as from the reverse of this, as before mentioned.

I likewise meant to have stated in former papers, that the "whip" or "switch"-tailed birds so-called in our northern counties and elsewhere, I have generally heard termed the "seythe"-tailed birds in contradistinction to the "sickle" or "sickled"-tailed birds. I prefer the latter if hard, and close, and short in feather.—NEWMARKET.

TUMBLER PIGEONS.

I AM much pleased with the notes of the "WILTSHIRE RECTOR," but I certainly differ from him in some of his remarks on "common Tumblers"—but they must tumble, they must be true to their name."

I candidly confess that it is a difficult matter to find a first-class lot of good Tumbler Pigeons that will tumble well. By tumbling well I mean that in going over the circle it is fairly kept, the head of the bird being in a straight line with the centre of the tail, no deviation to one side or the other, but true as an accurately turned wheel, and this done so quickly that great care is required not to overlook the action.

The next quality in a good Tumbler is to tumble without losing any of the height, if the birds are sky Tumblers. Young birds frequently lose a good deal, and particularly if they tumble two or three times at once before they fly forwards, but old grown birds ought not to lose any of their height in tumbling.

The next quality is the number of times they tumble in a given period of their flight or the distance they fly. I am here referring to sky Tumblers, and my opinion of them is in proportion to the greatest amount of the above qualities; or, in other words, the birds that tumble the greatest number of times, and the cleanest, in a perfectly circular direction, and with least loss of height, are the best sky Tumblers.

I differ from "WILTSHIRE RECTOR" in his classification of the Short-faced Tumblers being "the highest class." They belie their name in a great measure. I have had some of them, and have seen plenty, but have seen no tumbling from them, and therefore they should lose the false name they bear. The correct eye of the naturalist would, I think, at once pronounce them a malformation.

I differ from "WILTSHIRE RECTOR," also, with regard to the eye. If I had him here I could show him one bird with nearly a red eye that would astonish him with its tumbling qualities. It is, of course, a ground Tumbler, and feather-footed also. I have tried and been successful in raising some splendid feather-footed birds. One of the best Tumblers I ever had was a dark black-and-white feather-legged Tumbler. I took advantage of a son from him and the ground Tumbler referred to below, and obtained some of the best feather-legged birds imaginable. I like to see pearl eyes in Tumblers, but I have many that have not pearl eyes that are very good Tumblers.

The Rector seems not to like ground Tumblers. I confess they are my greatest favourites. I have one fine fellow which has great pride in his tumbling. He will, for ten or a dozen times together, if thrown from one's hand, tumble, and frequently twice together, before he alights on the hand again; and as I have described before, his tumbling is perfectly circular.

I find the best sky Tumblers come from a ground Tumbler crossed with a sky Tumbler. I obtained some beautiful light blue-barred Tumblers from a ground Tumbler and a sky Tumbler, but they do not in the second generation breed a healthy offspring, and I have broken three pairs of them to pair with the offspring of some dark blue ground Tumblers, in order to raise some dappled ones, and in one or two birds I have been successful, and the tumbling qualities are all I can wish for.

I have a flight of more than seventy Tumblers, and I imagine some of the best and neatest in the country. They are great

pets; I cannot kill one on any account when I look at the watery, young, innocent eye of my pets.

I am very fond of beautiful-shaped birds, Tumblers of course, also of colour. I think I have about ten pairs of Black and White Splashes, shape and colour grand, and I have preserved them in consequence—that is my pet colour. The next are Red Splashes, but they are not so numerous as they were forty or fifty years ago.

Whether this characteristic tumbling arises from some particular structure of the brain I know not, but I am sure that there is a much larger brain in the Tumbler Pigeon in proportion to bulk than can be found in any other of the great family of Columbidae, and I have uniformly found the best Tumblers the most sensible birds. I spend much time in watching their habits, their sympathies, and antipathies. I have them perfectly docile, and can call very frequently a dozen at once from the roof of the cote on to my head, and arms, and hands.

I believe the best Tumblers if kept too much on very stimulating food are most subject to vertigo and wasting. I should like to hear if any of your numerous readers have tried any experiments on the above diseases. I had a very valuable bird which began to waste, and became so light as to be merely bones and feathers, yet he always kept the feathers smooth. An old friend told me when he had birds in that way he invariably pulled out all the tail feathers. I am glad to say I have tried the experiment with my bird, and with perfect success. For vertigo I have tried a few remedies, but without success, but I have only seen one case.—R. W.

SOUTHAMPTON POULTRY SHOW.

THIS year's Show, held on the 10th, 11th, and 12th inst., consisted of considerably more than six hundred pens, and the Victoria Rooms proved far more eligible for the purposes of such a display than those hitherto used for this Exhibition, being better ventilated, and the light throughout good. The remarkable excellence of the Show as a whole was a matter of general congratulation, whilst most of the prize birds were such as have a very fair chance of holding good their high position at any meeting. There were but few *Spanish* fowls shown, and most of them scarcely in the good feather that could be wished. *Grey Pouter*s were especially good, and we believe many were claimed at the opening of the Show. *Cochins* were very fair. The *Brahma* classes, however, were the chief feature of the Show, the Dark-feathered being not very largely represented; but the Light-coloured were there in extraordinarily large classes, and of a quality not seen for many years past. The silver cup given to this variety caused an almost general entry from the very best blood in the kingdom. The *Game* fowls proved very good, but as yet hardly in perfect feather. *Hanboroughs* were generally so good that a visitor might easily have fancied he must be inspecting either a North Lancashire or Yorkshire show. *French* fowls were superior to those commonly shown. *Game Bantams*, *Trucks*, *Turkeys*, and *Geese* were especially noteworthy. Of *Pheasants*, strange to say, there was not a single entry.

Pigeons were never shown so numerously, nor of equal quality, at any of the preceding Southampton shows. The extra variety class of Pigeons contained many new varieties. There was a very good show of live *Foreign birds*, and also of *Mules* and *Couriers*.

Eggs and dead dressed poultry were especially worthy of note. A pair of young cocks, plucked and trussed for the table, a cross between the Grey Pouter hen and Light *Brahma* cock, actually weighed 16½ lbs., and the next best couple proved nearly as heavy. So much for the improvement in useful poultry. The Committee and Honorary Secretary were exceedingly attentive to the welfare of the birds.

SPANISH.—First, J. R. Rodbard, Winton. Second, J. Jenner, Lewes. Commended, J. Jenner; H. Loe, Appuldurcombe.

DORKINGS.—First, J. Smith, Shillinglee. Second, Dr. D. C. Campbell, Brentwood. Very Highly Commended, H. Pickles, jun., Farley. Highly Commended, St. J. Coventry, Wimborne; R. Pople, West Moulsey; W. Peacocke, Efford; J. Elgar, Newark; Hon. H. Fitzwilliam, Wentworth Woodhouse. Commended, R. Pople; J. Smith; A. Saunders, Alderbrook, Old Shirley; W. Stanford, jun., Steyning.

COCHINS.—First and Commended, F. W. Rust, Hastings. Second, J. Gardiner, Bristol. Third, J. R. Rodbard. Highly Commended, Rev. S. C. Hamerton, Warwick; G. White.

BRAHMAS (Dark).—First, G. L. Macpherson, Bracknell. Second, Rev. J. Ellis, Highly Commended, Rev. R. Parker, Ipswich. Commended, G. Meares; P. D. Maddox, Bitterne; J. H. Cuff, Metropolitan Cattle Market; C. F. Hore, Tunbridge.

BRAHMAS (Light).—First and Second, J. Pares, Postford. Very Highly Commended, H. M. Maynard, Holmewood. Highly Commended, F. Crowley, Alton. Commended, Miss B. Greene, Wickham, Farnham. *Chickens.*—First and Cup, R. Dowsett, Fleshey, Chesham. Second, F. Crook, Forest Hill. Very Highly Commended, H. Dowsett. Highly Commended, F. Crowley; F. Crook; H. M. Maynard. Commended, Mrs. Astley, Fring; J. Pares; W. H. Gutch; S. Felgate, Ipswich; C. H. Lang.

GAME (Black and other Reds).—First and Second, S. Matthews, Stowmarket. Highly Commended, H. C. Dear. Commended, T. H. Higden, Hove; C. F. Hore, North Stowmarket Park; W. Lyne, South Lanching.

GAME (Any other variety). First, T. Dyson, Halifax. Second, S. Matthews. Commended, Rev. T. L. Fremonger, Goodworth; H. Loe.

HAMBURGHS (Silver and Gold-pencilled).—First, R. Barter, Plymouth. Second, F. Pittis, jun., Newport, Isle of Wight. Highly Commended, H. Pickles, jun. Commended, F. Pittis, jun.

HAMBURGHS (Silver and Gold-spangled).—First and Cup for best pen F. Pittis, jun. Second, T. Blakenham, Teltunhall. Highly Commended, S. & R. Ashton, Mottram; H. Pickles, jun.; F. Pittis; R. Barter. Commended, J. Elgar.

POLANDS (Any variety).—First, G. W. Boothby, Lenth. Second, Mrs. Pettat, Ashle Rectory. Highly Commended, T. P. Edwards, Lyndhurst; Mrs. Pettat; H. Pickles, jun.

FRENCH.—First, Col. Stuart Wortley, Grove End Road, London. Second, H. M. Maynard. Highly Commended, Mrs. Astley; Mrs. L. Paget, Wimborne. Commended, Rev. N. J. Ridley, Newbury; H. S. Fraser, Headley.

ANY OTHER DISTINCT VARIETY.—First, J. Hinton, Hinton, Bath. Second, F. Pittis, jun. Highly Commended, J. Pares. Commended, W. Stanford, Steyning.

GAME BANTAMS.—First and Second, J. W. Kelleway, Merston Cottage, Isle of Wight. Highly Commended, J. W. Kelleway; C. Hore; J. W. Morris, Rochdale. Commended, W. G. Stevenson, Foxlease, Lymington.

BANTAMS (Any other variety).—First, Mrs. Pettat. Second, H. M. Maynard. Highly Commended, E. Cambridge, Bristol; H. Pickles, jun.

DUCKS (Aylesbury).—First, A. Saunders. Second, F. Crosswell, Hands-worthy. Highly Commended, F. Crosswell. Commended, Mrs. J. J. Maberly, Hawley Hurst, Petersfield; A. Saunders; F. Pittis, jun.

DUCKS (Any other variety).—First, C. Baker, Chelsea. Second, S. and R. Ashton. Highly Commended, Mrs. Hayne, Fordington. Commended, T. R. Hulbert, Old Akesford; H. S. Fraser; T. P. Edwards.

GESESE.—First, H. C. Bear. Second, Miss E. E. Williams, Harrington. Highly Commended, A. Saunders.

TURKEYS.—First, J. Elgar. Second and Highly Commended, St. J. Coventry.

PIGEONS.

POUTERS OR CROPPERS.—First and Second, R. Fulton, Deptford. Highly Commended, H. Yardley, Birmingham; P. H. Jones; W. Cole, Warwick. Commended, T. H. Evans, Lambeth.

TUMBLERS.—First, R. Fulton. Second, P. H. Jones. Highly Commended, Hawley & Horner, Bingley; J. Luffan, Farnham; R. Fulton; H. Yardley.

BALES.—First, R. Fulton. Second, Miss Coker, Aylesford. Highly Commended, Hawley & Horner; H. M. Maynard; J. Exter, Newcastle-on-Tyne. Commended, Miss Coker; P. H. Jones.

JACOBS.—First, Miss J. Millward, Newton St. Lee. Second, Hawley and Horner. Highly Commended, W. Green, Ryde; G. Hill, Winchester. Commended, H. Yardley; H. M. Maynard; J. W. Edge, Birmingham.

FANTAILS.—First and Second, Rev. W. S. Shaw, Bath. Very Highly Commended, H. Yardley. Highly Commended, S. A. Wyllie, East Moulsey; H. Yardley; Miss J. Millward. Commended, J. Luffan.

OWLS.—First, S. A. Wyllie. Second, P. H. Jones.

TURKISH.—First, Hawley & Horner. Second, J. W. Edge. Very Highly Commended, Mrs. Breet, Euxted, Uckfield. Highly Commended, H. Yardley.

CARRIES.—First and Second, R. Fulton. Highly Commended, S. Harding, Farnham; P. H. Jones; H. M. Maynard; J. Luffan; R. Wilson, Thirsk; P. B. Jones. Commended, H. Johnson, Farnham.

NUNS.—First, P. H. Jones. Second, R. Wilson, Thirsk.

ANY OTHER VARIETY.—First and Extra Third, W. S. Loder, Bathwick Hill, Bath. Second and Third, H. Yardley. Very Highly Commended, Mrs. Brunt. Highly Commended, Hawley & Horner; S. A. Wyllie; P. H. Jones; H. M. Maynard; W. S. Loder, Bathwick Hill, Bath; J. W. Edge, Commended, A. P. Maurice, Horward Grange, Basingstoke; H. Yardley; Hawley & Horner.

Cup for the greatest number of points in the Pigeon classes, R. Fulton.

CANARIES.

NORWICH Clear Yellow.—First, H. Vine, East Cowes. Second, E. Orme, Derby. Very Highly Commended, J. Bennett, Derby; R. J. Troake, Redland, Bristol; R. Mackley, Norwich. Highly Commended, J. Lennett; J. Exsson, Derby; H. Vine; W. Walter, Winchester. Commended, G. Cummings, Gloucester; J. Adams, Coventry; G. J. Barnesby, Derby; W. Walter.

NORWICH Clear Buff.—First, E. Orme. Second, R. Mackley. Very Highly Commended, J. Adams; W. Heap, Horton, Bradford; H. Apted, Breadwater, Worthing; H. Vine. Highly Commended, G. J. Barnesby; J. Bexson; W. Walter; R. Mackley. Commended, E. Orme.

NORWICH (Marked or Variegated Yellow).—First, E. Orme. Second, R. Mackley. Very Highly Commended, J. Bexson; W. Walter. Highly Commended, W. Walter. Commended, W. D. Frosser, Wandsworth; W. Walter; R. Mackley.

NORWICH (Marked or Variegated Buff).—First, E. Orme. Second, W. Inson, Redlands, Bristol. Very Highly Commended, J. Bennett, Derby; W. Walter. Highly Commended, W. Walter; R. Mackley. Commended, R. J. Troake; W. Walter.

BELGIAN (Clear Yellow).—First and Very Highly Commended, O. Nicholson, Llandport. Second, R. Mackley. Highly Commended, O. Hailes, Southampton.

BELGIAN Clear Buff.—First, J. Bexson; Second, O. Nicholson. Very Highly Commended, J. Baxter; T. Moore, Fareham; R. Mackley. Highly Commended, O. Nicholson.

BELGIAN (Variegated or Marked Yellow).—First, O. Nicholson. Second, H. Vine. Highly Commended, J. Bexson; T. Moore. Commended, W. Clark, Nottingham.

BELGIAN (Variegated or Marked Buff).—First, O. Nicholson. Second, J. Bexson. Very Highly Commended, H. Vine.

LIZARD (Golden-spangled).—First, G. Harrison, Canterbury. Second, F. W. Fairbrass, Canterbury. Very Highly Commended, Rev. W. Ward, Canterbury. Highly Commended, H. Vine. Commended, T. Fairbrass, Canterbury; J. Bexson.

LIZARD (Silver-spangled).—First, T. Fairbrass. Second, W. Clark. Highly Commended, J. Bexson; H. Vine.

GOLDFINCH MULE (Jonque).—First and Second, G. J. Barnesby. Very Highly Commended, G. J. Barnesby; J. Exsson; H. Vine; T. Carrington, Derby; R. Mackley.

GOLDFINCH MULE (Nealy).—First, G. J. Barnesby. Second, R. Mackley. Very Highly Commended, G. J. Barnesby; T. Carrington; R. Mackley. Highly Commended, H. Vine. Commended, G. J. Barnesby; R. J. Troake; W. Inson.

LINNET MULE.—First and Second, G. J. Barnesby.

CANARY (Any other variety).—First, R. J. Troake. Second, H. Vine. Third, W. A. Blakston, Sunderland. Very Highly Commended, W. Walter; R. Mackley. Highly Commended, W. J. Toon, Kettering; O. Nicholson.

Cup for greatest number of points in Canary and Mule Classes, G. J. Barnesby.

BRITISH BIRDS.

BLITZFINSCH.—Prize, H. Vine.

GOLDFINCH.—Prize, H. Vine. Very Highly Commended, W. Walter. Commended, O. Nicholson.

LINNET.—Prize, W. Walter. Highly Commended, H. Bromley, Southampton.

SKYLARK.—Prize, Mrs. Goulden. Very Highly Commended, H. Vine. Commended, T. Stewart, Glen Ayre, Southampton.

WOODLARK.—Prize, W. Walter. Highly Commended, O. Nicholson.

BLACKBIRD.—Prize, T. Hewlett, Southampton. Very Highly Commended, J. Titheridge, Winchester.

SONG THRUSH.—Prize, W. Walter.

STARLING.—Prize, H. Vine. Commended, W. Walter.

SISKIN.—Prize, Miss M. Harfield, Shirley, Southampton.

ANY OTHER VARIETY.—First, A. G. Hubbard, Southampton. Second, D. Barnes, Portswood, Southampton. Third, O. Nicholson. Fourth, T. Carrington.

FOREIGN BIRDS.

LORIS (Any variety).—Prize, W. Walter.

LOVE BIRDS.—Prize, W. B. Bailey.

PARAQUETS (Any variety).—Prize, W. Walter.

JAVA SPARROWS.—Prize, W. Walter. Commended, W. B. Bailey, Purfleet.

WIDAL.—Prize, W. E. Bailey.

CARDINALS.—Prize, W. E. Bailey.

BISHOPS.—Prize, W. B. Bailey.

WAXBILLS (Any variety).—Prize, Miss M. Harfield. Very Highly Commended, W. Walter.

FOREIGN (Any other variety).—First, W. B. Bailey. Second, Miss M. Harfield.

Edward Hewitt, Esq., of Birmingham, judged the *Poultry and Pigeons*; A. Willmore, Esq., of London, *Canaries*; and Wm. Goodwin, Esq., of London, all *Foreign birds*.

GOLDFINCH MULE CANARIES.

THE queries of your correspondent, "ROBBIE BURNS," "How Goldfinch mules are judged in England, and how they ought to be judged," include widely different matters, and the answers are dependant greatly on the classification. In some schedules "nearest the Canary" is the standard—a definition so manifestly absurd as to need no comment. Last week, at a local show, I saw a splendid evenly-marked mule displaced by one marked on one wing only, on the ground that it was "nearest the Canary!"

The mule most difficult to breed is one absolutely clean, and it therefore ought to occupy the highest position. Next to this should rank an evenly-marked bird; then ticked and unevenly marked; and lastly, dark self-coloured mules. Colour, condition, and size are taken into consideration, and, all other points being equal, a bird which excelled in either would win.

A Jonque mule (formerly in the possession of Howarth Ashton, Esq., of Manchester, but now the property of John Young, Esq., of Monkwearmouth, who has, perhaps, the finest collection of mules in England), which for size, colour, and markings was considered the best mule of his class in the country, and has carried Mr. Ashton's colours to the front in many an all England show, is evenly marked on each wing, and beautifully pencilled on the eyes. He is named Edward I., and the last time I saw his majesty he was surrounded by such a group of satellites as it is seldom one man's good fortune to possess. Edward II., a Jonque cock, similarly marked, but with the addition of a black feather on either side of the tail; Black-eyed Susan, an evenly-marked and pencilled-eyed buff beauty; Cloth of Gold, a clean Jonque cock; Snowdrop, a clean buff cock, with Snowflake and Snowdrift, two spotless hennies at his side, were among the number. The past season, however, may have given birth to new gems, and I have no doubt that Mr. Doel, Mr. Barnesby, Mr. Shiel, and other noted mule-breeders will charm us with a peep at some of their treasures at the approaching winter exhibitions.—W. A. BLAKSTON.

THE CAPE BEES.

I THINK it will be found that the two native varieties of the honey bee referred to by Mr. Woodbury's South African correspondent are nothing else than mongrel varieties of *Apis fasciata* and *Apis mellifica*. I very much doubt, because against all experience, that the pure African bee is to be found uncontaminated in presence of any known variety of *A. mellifica*, and hence I am inclined to think that both the varieties alluded to will be found to be mongrel races.

It would appear from Mr. F. Smith, that "the small black

bee possibly is the *A. Adansonii* of Latreille;" but I understood that the *A. Adansonii* of Latreille was a variegated bee, and agreed with *A. fasciata* in size and colour, differing only in its darker hair. It is said that this form of variegated bee occurs at the Cape. If so, I take it to be the "diminutive of the Ligurian" referred to by Mr. Woodbury's correspondent—*A. Adansonii*. I also understand that together with this variegated form, there occur at the Cape transitions of all kinds to a nearly uniform dark one, and that the darker variety only differs from the British bee in its smaller size. This seems to me to be the other variety referred to, which Mr. Woodbury has commissioned, and which is described as being nearly identical with the *A. unicolor* of Latreille, which abounds in the Mauritius and Madagascar, and which M. Gerslacker says "differs from the north German bee (*A. mellifica*), only in its smaller size." In short, I expect that the African "niggers" on their way to England will resemble somewhat those propagated by myself (only darker), by the crossings of the *A. mellifica* with the *A. fasciata* in my possession.

That the characteristics of each variety should be thus maintained so conspicuously, as is represented to exist at the Cape, is one of those mysteries which it is difficult to solve, though a bolder acquaintance with facts might throw some light upon it. Where two opposing influences are at work it is natural to suppose that the strongest or largest will have the mastery. In this country it will be found that the Ligurian race will have much to contend against in this respect for many long years to come; but even when its propagation shall arrive at that point, when both the Italian and British influence shall be nearly equalised, I believe that even then in certain localities the Ligurian race will be found to prevail over the other race, and *vice versa*, just as is represented at the Cape with regard to the Egyptian and British bee.

I fear, then, that Mr. Woodbury in getting possession of these African "niggers," so far from obtaining any new race of bee, will only be renewing his acquaintance with hybrid descendants of his old "friend" (!) *A. fasciata*, only with a large preponderance of the black element; and that in making a choice of these for importation over the so-called "diminutive Ligurian," mentioned by his correspondent, so far as irascibility of temper is concerned, he will only be avoiding Scylla to fall into Charybdis.

In thus forming an opinion, however, I need not say that I shall be glad if that opinion prove incorrect. In any case, all apiarians must owe Mr. Woodbury a debt of thanks for his indefatigable and persevering exertions in this matter.

One or two very interesting topics have been recently mooted by your excellent correspondent, "R. S.," to which I hope to direct my attention at some future time, and to which other apiarians will, I doubt not, lend their aid towards a solution.—J. Lowe.

INTRODUCING LIGURIAN QUEENS.

The following is an account of our experience with six Ligurian queen bees we recently obtained from Mr. Woodbury. We first asked his advice about how we were to introduce them to the black bees, and were referred by him to the number of THE JOURNAL OF HORTICULTURE for the 5th of September, 1867. We got it, and were then prepared to act.

On the 15th of October we had a note saying that the bees were to leave Switzerland in a few days. We let the black queens remain in their hives four days after that, and then removed five of them, thinking that within five days their foreign rivals would be forwarded to take their place. We were disappointed, however, for instead of five days it was twenty ere they arrived.

My neighbour, who was to receive three of the six queens, became very disheartened; his bees came out, and seemed careless about going back again. He expected to lose all; around his hives the bees were lying dead. He shut them up, then dysentery began in two of the hives, and when the queens came, there was a great number of his bees dead in two of his hives (they were very strong hives to begin with). He cleaned them out, and tried one of the queens on a comb; she was received cheerfully. The other two had to be put into wire cages, and left for two days. He has now succeeded with all three.

A day before the Italian queens arrived I found a young queen cast out from each of my two hives, from which I had taken the queens about seventeen days before. This told me there had been queen-making going on, so I made a search

before putting in the new ones, and found a fine large queen in each, and four queen cells. This rather puzzled me; how was I to do now? As it was very cold, how was I to manage to keep the new queens five days, as Mr. Woodbury said the bees should be kept five days without a queen before putting in the new ones? The five queens we took out first died in ten days, and the frost being now so severe, I was afraid to keep them a day from the hives after the journey from Switzerland. I saw no alternative but to risk them at once; so I placed two of them each into a cage, and put them into their hives. I had not taken the queen from my third hive, so I went in search of her, and saw her on a comb, but ere I could take her off, she was out of sight. I then searched the combs four times over, but could see nothing of her, so I gave it up in despair till next day, when we found her outside of the house. It was a very hard frost all night, and the sun not making his appearance, I durst not open the hive, so I thought of just risking the new queen in at the opening or feeding hole at the top of the hive. I opened the box to take her, but found her lying on the bottom, and her companions along with her, to all appearance dead, so I shook her out on my hand (the reader may conceive my feelings after all my trouble); she seemed a beauty. I ran to the fireside, warmed my hand, held it over her, breathed between my hands to warm her, and was laughed at by my wife, who told me I was getting "bee-daft." The heat had the desired effect, however, for the queen began to move, and in ten minutes was on her feet. I put her into a box, placed a piece of glass over it, wrapped the box in warm flannel, ran to the bee house with her, and put the box on the feeding hole. I left the bees there, and examined the three hives at the end of four days, and found the queens in all doing well. I should have stated that my two queens that were caged at midday were released from their confinement by the bees excavating their cages out of the comb by next forenoon.

We have managed far better than we expected. We feared that the frosty nights would kill the queens on the journey. My neighbour and myself had both had one that was more like dead than alive.—H. L.

THE BERKSHIRE HIVE.

I CAN fully endorse what is said by "S. B." as to the advantages of the Berkshire bee hive, which I have used with the greatest success, and which I believe to be for ordinary bee-keepers the most satisfactory hive known. It is somewhat on the principle of the Canadian hive, than which nothing can be more simple or efficient for taking and storing honey.

Mr. Sadler's hives and bee houses both deserve notice, and I am surprised that they have only just found their way to the Bee-keepers' Chronicle.

This year I have taken 68 lbs. of honey from three hives, leaving, of course, the stocks well supplied for the winter. It is not true that the hives never throw off any swarms, for if exposed to the sun the bees are sure to swarm; they require to be kept entirely in the shade. My best stock swarmed twice this year, and made no honey in the supers because they were exposed to the sun all the previous season, and consequently prepared for swarming early this spring. I have tried many hives, but none with equal success to that of the Berkshire Hive.—HALCYON.

WAXEN SHEETS.

In reply to "A LANARKSHIRE BEE-KEEPER" in your last number, I would observe that no wax sheet which I have purchased or made is of uniform thickness; the wax, tending downwards when the board or glass is dipped into it, accumulates in a greater thickness on the lower side of the sheet, and if care be not used to hang the sheet by its thickest edge a breakdown frequently follows. The perforation which he describes I have occasionally observed in impressed sheets, but not to any serious extent, and never, so far, in plain sheets.

If "A LANARKSHIRE BEE-KEEPER" will refer to my letter in your number of September 10th he will see that I was speaking of impressed sheets, when I said that I had known worker comb built upon them by queenless stocks. This I have seen so frequently that I think I may say that it is the rule that drone comb is not built until the comb is brought below the level of the sheet; but in respect to plain sheets I may now say, that on the only occasion within my knowledge of bees build-

ing on such when queenless, a somewhat similar result ensued. On the 5th of July this year a stock of pure Ligurians having refused to swarm or work in supers, I divided the hive (a frame box of 20½ inches square) by a partition in the middle, and gave to the queenless half an outside frame with a plain sheet; the queen was hatched on the 20th, by which time the sheet was fully worked up, the greater part of it with worker cells, but a little drone comb round the edges; this comb, mostly sealed honey, was removed before the queen began to lay. With regard to the use of plain sheets in supers I can say nothing, not having yet tried them, but purpose doing so next year.

I may further inform your correspondent that I have never purchased wax sheets either in London or Ayrshire in smaller quantities than three dozen, and that I have paid in London 6s., and in Ayrshire 5s. a-dozen, besides packing-case, &c. I cannot undertake to make sheets for your correspondent, but as to their price it may suffice to say, that plain sheets somewhat thicker than the impressed ones weigh thirty to the pound, when trimmed for Woodbury frames, and the price of wax being 2s. per lb., makes the price of a sheet somewhat less than 1d. As to the labour of their construction, I can easily, by the method described in my former letter, turn out ten dozen in an hour, and have little doubt that with the aid of another pair of hands they could be impressed in two hours. The profit which the makers realise upon their sale at 6s. a-dozen may easily be reckoned.—*APICOLA*.

HOW TO SWEEP THE FLOOR.

In the days of our Puritan grandmothers, no girl was considered fit to receive proposals of marriage till she could make a good hemlock broom; to know how to make a broom in those old days, we presume, was always preceded by the knowledge of its use. But in these later times, many a young lady not only offers herself in the matrimonial market, but absolutely gets married and undertakes to manage her house without knowing how to use a broom that some one else has made. We have seen a broom used so unskillfully, that one would almost think the person engaged in using it was endeavouring to change the place of the dust from the floor to the furniture. It requires some science, or at least some skill, to use a broom well, as it does to do anything else.

To use a broom skilfully, the handle should incline forward and not backward, as is often the case. If the top of the broom inclines forward beyond the part next the floor, it will prevent much of the dust from rising into the air, and will carry it along by a gently sliding motion towards the place where it is to be disposed of.

If, on the other hand, the handle of the broom inclines backwards, the dust is sent into the air by a kind of a jerk, to the great annoyance of those who occupy the room, and to the great detriment of everything the apartment contains. More than this, it wears off the threads of the carpet quicker, injures the paint more, if the room is uncarpeted, and destroys the broom sooner, than if the sweeping was done in a more rational way.

A brush of bristles is always better to sweep a carpet, as it is less liable "to kick up a dust," or to injure the texture of the carpet. Moistened tea leaves thrown over a carpet before sweeping, will help to prevent the dust from rising, and on account of the peculiar property of the tea infusion, they will not injure the colour of the cloth. After the first snowfall, carpets may be cleaned of dust by throwing a little hard snow on them when the room is cold, and quickly sweeping it off.

OUR LETTER BOX.

CHINESE GEESSE—CHARACTERISTICS OF DORKINGS AND BRAHMAS (Norvic).—We know nothing of Messrs. Lucas' sale. Chinese Geese lay at all times. We have known them lay, sit, and rear their young in mid-winter. The principal characteristics of Dorking and Brahma cockerels are size and weight, but of course the latter is not accompanied by symmetry. They are lanky and narrow. Golden-pencilled Hamburgs lay more eggs than either Brahmas or French fowls, but their eggs are smaller. The French lay the largest eggs. They, like the Hamburgs, are non-sitters.

QUANTITY OF FOOD FOR FOWLS (An Amateur).—It is quite impossible to give any quantity as the average consumption of food by a given number of fowls, unless we know every particular—whether confined or at liberty, and the nature of their run. We do not like your feeding. The morning feed of corn is a good one; barley is better than wheat. The midday and evening feeds are bad. Boiled Potatoes are bad feeding. They make bad flesh and flat, and they do not promote laying. Pollard is bad. Kitchen scraps are good. You will do better if you will adopt

the following dietary:—In the morning, at daybreak, barley; midday, ground oats slaked with water or milk, and in the evening whole corn, either barley or Indian corn; the former preferable, the latter useful for a change. The old moulting hens will not lay in the winter. The pullets of last spring should do so, and will as soon as you alter your style of food. No hens, however well fed, will lay in the winter. You must form your own idea of the necessary quantity of food from observation. The better their condition the less they will eat. Rice is utterly worthless.

COCHIN-CHINA HEN NOT LAYING (S. B.).—Either your Cochin hen was too fat to lay, or she ate her eggs, or they were taken by some one or something. It is against nature that a hen should lay one egg and then leave off. Judging from her weight we should say she was very fat. At her age she will not lay at this time of year; but when Christmas is turned bring her down in condition till she is comparatively thin, and we believe you will find her a layer.

BREEDING BUFF COCHIN-CHINAS (Lemon Buff).—What colour do you want to breed? We should prefer the dark cockerel with the light hens.

PROMOTING SIZE IN FOWLS (C. L.).—Nothing can be more fallacious than your friend's advice, to feed less nourishingly. You want size, and that can only be produced by good feeding when the birds are growing. If you feed on bran you will have a lanky, narrow, knock-kneed bird, that will pass all his time sitting on his heels. A growing bird will not fatten, all the support goes to make scaffolding, and to supply thew and sinew. Your 8-lb. bird had done growing at eight months old. Barley-meal and ground oats are good, so is a little whole barley. We do not approve of wheat, bran, Indianmeal, or peameal. A little Indian corn may be given at times. The secret of making large fowls is to feed judiciously from the first. Growth cannot be made afterwards. Weight may be added, but it is such as you saw in the fowl you mention, and such as you would obtain in a Capon. Hatch early, feed often on chopped egg and cooked meat, bread and milk, ground oats slaked with milk, bread crumbs, tallow, &c. When growth has ceased, feed them as adults; meal night and morning, whole corn in the day. Judges are not infallible, and if the cock has done as much as you say, continue to show him.

HEN-CKOCK (Mr. A. P.).—Your Black Spanish hen, which has been laying for the last two years, and this year after the moult has feathers like those of a cock, tail and hackle, and in colour rich glossy black, having a metallic green lustre, is not a phenomenon. It is a change which often occurs, and though the sex is changed only in appearance, yet she will lay no more eggs.

ROUP PILLS (J. Mowcroft).—Messrs. Daily, 113, Mount Street, Grovesnor Square, London, W.

HANLEY POULTRY SHOW (T. Dean).—Our note about Keighley Poultry Show, at page 352, should have been headed "Hanley Poultry Show," and our observation applies to this. We see no reason to pursue the subject; if you can show any unfair proceedings we will aid in exposing them.

CROSSING TOUTLOUSE AND NORFOLK GEESSE—EGGS UNFERTILE (A. B.).—You may safely allow the Toutlouise Gander to run with the Norfolk Geese. You are altogether mistaken about the eggs; those that remain perfectly clear have never been impregnated—they would have remained clear for six months. There has never been the germ of life in such an egg, and there can consequently be neither development, death, nor decay.

BALDHEAD AND BEARD PIGEONS.—A correspondent says that these are very difficult varieties to breed, and that he, "A Beard," would readily subscribe, as would many others, for prizes to be awarded to them in separate classes.

LARGE HIVES (Inquirer).—If, as we suppose, you intend to deepen your hives permanently by means of ekes, it had better be done in the spring as soon as they become tolerably populous. It may be as well to change their floor boards, but we do not deem it very essential. Waxen sheets should first be slightly warmed, so as not to chip before the knife or scissors, then make incisions from a quarter to three-eighths of an inch deep, and about an inch apart along the upper edge. Next warm the wax a little more, and bend over each portion so divided alternately from right to left until they stand at right angles with the sheet itself, when, if our description has been sufficiently clear to be intelligible, it will be found easy to cement the foundation thus formed to a comb bar, by means of melted wax. We see no reason why your hives should not travel safely if you can get the crate carefully handled and kept in its proper position. Tie the hives up to cloth of open texture (cheese cloth), invert them, and pack them firmly with straw, taking care that ventilation is perfectly unimpeded in every case.

FOOD FOR BEES (E. Hoare).—We always use simple syrup made of lump sugar in the proportion of three parts of sugar to two of water (by weight), and boiled a minute or two. When administered by means of an inverted bottle this really leaves nothing to be desired. Treacle should never be used for feeding bees.

FEEDING BEES IN WINTER.—"G. S. T." asks for the best method of feeding bees in winter, and as we never attempt doing so, we shall be obliged by a reply from any one who has successfully fed bees at that season.

BUTTERFLIES AND MOTHS (A Young Entomologist).—We cannot recommend dealers. There is no serial relative to Lepidoptera publishing in parts. If you need a cheap illustrated book on the British Lepidoptera, purchase Stinton's "Manual of Butterflies and Moths."

GREEK WINES (Rev. W. K. P.).—We have already stated that Kephisia and St. Elie are two of the most refreshing wines that we know. All the Greek wines are pure and unbranded. Why not call at Mr. Denman's, in Piccadilly, and taste the wines? You will find all the information you ask for in a small volume he has published. It is well written, and tells much that you will like to know.

From observations taken near London during the last forty-one years, the average day temperature of the week is 47.8°; and its night temperature 34.1°. The greatest heat was 62°, on the 1st, 1857; and the lowest cold 14°, on the 30th, 1856. The greatest fall of rain was 1.21 inch.

SOME NOTES ON FERNS, HARDY AND EXOTIC.

FERNS are ever worthy of admiration, but if I admire them more at one season than another, now is the time,

"When bleak November's winds are blowing,
Baith snell and keen."

When summer flowers lose their beauty and fade away, Ferns are lovely and graceful as ever; they are plants for everybody, and are to be found in the garden of the cottager, in the small greenhouse of the man of limited means, and in the garden of the nobleman, who can afford to build large conservatories where tree Ferns may luxuriate in abundant space.

First, I will jot down some notes about hardy Ferns, which are very easily managed, and the nurserymen's lists of which are numerous, especially in varieties of the normal forms of British species. These can be purchased at a cheap rate from the dealers in them, but are not so interesting to the enthusiastic cultivator as plants which have been collected during a holiday tour, and which have been obtained at the expense of many a fatiguing journey over hill and dale, and sometimes at much personal risk.

Some of the rarest of our native species are difficult to manage under cultivation, and require peculiar treatment to have them in a flourishing condition. The best place out of doors for them is a position partially shaded, but not too much confined, as they can bear a little exposure.

I will notice a few of the most interesting native sorts which I have successfully cultivated, and there is none more worthy of notice than the true Maiden-hair, *Adiantum capillus-Veneris*. It is one of the rarest of our native Ferns, and is found in tolerable abundance at Tintagel, in Cornwall. It grows best in a moist warm temperature; in fact, it pines away and dies in the open air, and just manages to live in a greenhouse. I grow it in the plant stove in a compost of turfy peat, a small portion of sandy loam, and a few rough pieces of charcoal, placing plenty of drainage at the bottom of the flower pot.

Asplenium marinum requires the same treatment. I had a large plant of it which threw up fronds 18 inches long in the stove; it also succeeds well in a vinery where it is partially shaded by the Vines during the season of its growth; the moist atmosphere which the Vines require during the growing season just suits it. It does not succeed nearly so well in a cool greenhouse. I was planting a specimen of it in a rockwork I formed out of doors in the spring of the present year, when a lady, visiting here, told me it was useless planting it, as she had proved that it would not so live in the neighbourhood of London. My plant looks healthy as yet; it has just been covered with a bell-glass, which will be allowed to remain on all the winter, and I have the hope that under careful management it will succeed. It grows and thrives in an exposed position on the north shore of the Firth of Forth, or did grow eight years ago, but the spot was often visited by collectors, and the plants were fast disappearing.

Ceterach officinarum is another interesting little Fern which I obtained from an old wall, where it grows naturally, in a cottage garden about two miles from Godalming, in Surrey. It succeeds well in a greenhouse temperature, or out of doors. I have raised numbers of plants from spores of this species. To cultivate it I half fill a 6-inch pot with crocks and broken bricks, placing some of the fibrous part of turfy loam over them to prevent the compost from mixing with them. The material in which they are potted consists of good turfy yellow loam one part, mortar rubbish one part, and one part bricks broken into small pieces, with a little silver sand. I raise the compost in the form of a mound in the centre of the pot. A 6-inch pot will hold six plants, one on the top of the mound in the centre, and the others in a circle round it. This Fern must be kept very dry in winter, and only just moist in the growing season.

To raise young plants from spores, fill a pot with the same material which I have recommended for growing the plants in, up to within 1 inch of the rim, then place some small pieces of broken bricks on the surface, and lay over them the fronds with ripe spores, placing a square of glass over all. I prepared a pot in this way, and the young plants came up in dozens all over the surface of the bricks: a green moss-like appearance first showed itself, and from this the fronds ultimately protruded. The plant I have out of doors is healthy, and, under a bell-glass, will, I hope, survive the winter at this place.

Allosorus crispus is another pretty little Fern, which I brought from its native mountain home on the Eldon hills, near Melrose, in Scotland, where it grows abundantly. It here flourishes out of doors, and does not require pot-culture. It has been grown here for five years.

Polypodium dryopteris and *P. phegopteris*, natives of the Scotch mountains, succeed well here. I brought the plants from the highest part of the Cheviot range, where they grow abundantly. *Allosorus crispus* is also found there in dense tufts, 2 feet in diameter, clinging to the face of the rocks, and living on the smallest amount of nutriment.

Polypodium vulgare cambricum, is an easily-cultivated Fern which ought to be in every collection; it retains its very pleasing shade of green throughout the winter; it is well adapted for pot-culture, and it is easily propagated by division.

Of *Scelopendrium vulgare*, the numerous varieties are very interesting, and easily cultivated. The variety *crispum* is very pretty, and does well in the rockwork out of doors; it is also fine for pot-culture, and easily increased by division.

Athyrium Filix-femina, the Lady Fern—there are numerous forms of this graceful Fern now, most of them worthy of cultivation. I have grown the variety *cristatum* for a number of years, and I admire it much. I raised a large number from spores, and the young plants nearly all came the same as the parent. This Fern thrives well in a compost containing a large portion of peat.

Cystopteris fragilis is another easily-cultivated species. The fronds of this Fern do not last long, but are renewed.

throughout the summer, although the best fronds are those produced first. The variety *Dickiana* is a very neat form of it; the fronds are more upright, and very much shorter, it is a very neat little plant for pot-culture, and is also reproduced by spores.

Trichomanes radicans I have never attempted to grow, either out of doors or in the greenhouse. I grew it in a cool stove, and the treatment seemed to suit it; it was kept under a bell-glass, and the pot in which it grew was never watered; it was plunged in another pot, and the intervening space filled with sand, which was always kept moist. The plant was potted in turfy peat, with some rough pieces of charcoal and broken bricks. It will also succeed in the greenhouse, but the plants must always be under a bell-glass, and shaded.

One more hardy Fern I will notice, and that is the *Botrychium lunaria*. I well remember walking eight miles, after a hard day's work, to the haunt of this plant, guided by a friend, who had gathered specimens of it. We searched until dark, and had to retrace our steps without meeting with a single specimen. It grows at "St. Martha's-on-the-Hill," near Guildford. I have dried specimens which my friend found there, but I would have been more pleased to have discovered it myself. The *Botrychium* is not easily cultivated, and requires careful management to grow it well; it ought to be potted and grown in a cold frame.

On Exotic Ferns I will not make any lengthened remarks. It is not necessary to maintain a high temperature during the winter months; in fact, I think it injurious. 55° are a good night temperature, or in very cold weather 50° will be enough, and it will not be injurious to the majority of stove plants. There will only be disappointment in summer if plants are unduly excited during the winter months. I believe manure in any form to be injurious to Ferns, and ammonia from the evaporating troughs does not seem to suit them. Watering is very important; they will never succeed with stagnant water near the roots, therefore see that good drainage is secured, and water sparingly during the winter, but never allow the plants to be dust-dry, and always use rain water. This ought never to be allowed to run to waste; large tanks ought to be provided in all houses, and placed, if possible, where the hot-water pipes will warm the water a little.

There have been some interesting additions to the numbers of Exotic Ferns within the last few years; foremost amongst them is a very pretty *Lomaria*, named *ciliata*, introduced by Messrs. Veitch, of Chelsea, from New Caledonia; it is one of the most distinct and elegant of the species. I have it growing freely in a cool stove. *Adiantum concinnum latum* is another of their more recent introductions; it is very pretty, and is said to be a useful exhibition sort. The true *Adiantum farleyense* is still scarce, and is not yet within the reach of everyone. It is a very fine plant, the beauty of the individual fronds cannot be surpassed; it seems to be of moderately free growth. *Lomaria zamiaefolia* is a free-growing distinct sort, and will succeed in a greenhouse. *Neottoptaris australasica*, another greenhouse species, is a grand Fern, and a full-grown specimen of it is a noble feature in a collection. It is easily managed, and will well repay all attention. It will, like most Ferns, grow best in a moist, rather warm atmosphere.

Dicksonia antarctica I will just mention as a most desirable species to grow; it is a tree Fern, but is very fine in its young state; it succeeds as well in a greenhouse as in a stove temperature. It is one of the sorts which thrips are fond of, and they will spoil the beauty of any Fern. The best cure for this is smoking the house with tobacco until it is cleared of them. J. DOUGLAS.

GROWING FRUIT FOR MARKET AT LITTLE SUTTON, CHISWICK.

MR. FRANCIS DANCER'S.

MR. DANCER is so well known in the horticultural world as an able and experienced cultivator, that further introduction is unnecessary. He is one of the largest and most successful of our great growers of fruit for market. If about Fulham, Deptford, and other places our greatest vegetable gardens are to be seen, assuredly at Chiswick will be found some of the finest, best managed, and most productive fruit gardens, from which Covent Garden receives a goodly portion of its enormous supplies.

The fruit gardens around Chiswick form, indeed, quite a feature of the place, as much so as do the Lettuces and Cab-

bages of Fulham, the Onions and Cucumbers of Sandy, or the blue Lavender of Mitcham. It is curious, and instructive as well, to observe how certain districts become devoted to the cultivation of one particular product. This is especially noticeable in market gardening. It is even so with fruits. Locality and soil are not alike suitable for all classes of plants, or every system of culture, neither will every variety of fruit succeed equally well in the same place. Now, as the object of growing fruit for market is mainly that of profit, it is perfectly natural to suppose, when we see a certain district chiefly devoted to the cultivation of certain things in certain ways, that that system is a profitable and proper one.

The specialities of fruit culture about Chiswick, and those in which Mr. Dancer particularly excels, are:—1st, Plums, which are cultivated on a very large scale, and most successfully. Every season the trees are heavily laden, and literally breaking down with their enormous crops of large and handsome fruit. 2nd, Pears, which are also largely and well cultivated, but not quite so extensively as Plums; 3rd, Apples; 4th, Currants, which last are an extremely pet subject of Mr. Dancer's, and one deserving of especial notice.

Having now had for some years abundant opportunities, through Mr. Dancer's kindness, of observing all the various methods and details of his culture and the results, I have been enabled to form some opinion of their respective value, however slight. Although the few observations I am about to make may refer chiefly to the results of the past season, which was in many respects a very exceptional one, the conclusions I have tried to arrive at, or the lessons learned therefrom, are the impressions of a series of years.

There is, I may premise, a very great difference between growing fruit for market and growing fruit for a gentleman's table. The method of cultivation, and the end desired—good fruit, may be the same, yet the one is generally for quantity, while the other is for quality and variety. The best fruits in quality are seldom the most profitable for general market purposes. Usually the highest-flavoured are the most delicate growers and least productive; and again, a certain variety may have all the good qualities, yet if it is not known in market it will not sell. A fruit to become a profitable market variety must be well known. A particular colour, even, will frequently cause its rejection in Covent Garden. Tastes change, however, and a variety which may at one time be much disliked may afterwards become very popular. The masses of the people, however, the London mechanic and his wife, who are the great consumers of Covent Garden fruit, appreciate and care but very little whether a fruit is fully up to any horticultural standard of perfection or not, provided they have plenty for their money. Quantity is evidently more prized than quality, especially if the latter is attended with scarcity.

Of Plums, one of the principal varieties cultivated by Mr. Dancer is Gisborne's, a rather shabby-looking, medium-sized, oval, yellow Plum, with a rather firm yellow flesh, not very juicy; neither is it of very excellent flavour in general. In the past summer, however, I tasted some fruit which were very fine indeed, and they were of an extraordinary size, although the trees were all very heavily laden with the crop. They were so large and so highly coloured that they could scarcely be distinguished from the fruit of the Jefferson. The flesh parts freely from the stone, whereas the Jefferson is somewhat of a clingstone.

Gisborne's, or Gisborne's Early, is a favourite Plum in Covent Garden. Its excellent qualities are so well known that it commands a very ready sale. As a tart Plum it is much in request, and as a preserving Plum it has no rival. It is first-rate for the latter purpose. This is one of the most profitable Plums to cultivate. The tree is hardy, not a very tall grower, and a most abundant bearer. It is very rarely indeed that Mr. Dancer misses having a crop of Gisborne's; during the past season the trees were not so loaded as usual, still the fruit was finer and larger, and consequently filled the measures quickly. I counted on some twigs, and there were plenty such, about two dozen fruit within the space of 12 inches. I am afraid to say how many trees Mr. Dancer cultivates of this variety, or how many bushels of fruit are gathered annually. I know, however, that one day there were no less than 153 bushels of this sort sent to market. This is Plum culture in earnest. Gisborne's is one of the earliest Plums to ripen, but Mr. Dancer generally gathers all his fruit before they have arrived at that stage. Nearly all the Plums sent to market are gathered from the trees in this half-ripe state. They may not be quite so good for dessert, but as they are principally used for tarts, &c.,

it matters little. It does not pay a Plum cultivator to wait until the fruit are quite ripe; they would not carry to market in good condition, and the losses arising from spoiled fruit, through bad weather and other causes, are sometimes very serious indeed. A day of rain makes sad havoc amongst ripe Plums; I have seen hundreds of bushels destroyed; the skin cracks, and the fruit splits and is totally spoiled. Mr. Dancer runs no risks of this sort, but gathers the fruit as soon as it will sell.

Another variety of Plum, largely cultivated, and held very high in Mr. Dancer's estimation, is the Prince of Wales, which is a medium-sized roundish fruit, with a bright purplish skin. This is also of second-rate quality; the flesh is somewhat coarse and of a yellowish colour. It belongs to what is called the Orleans class, and is a most excellent culinary variety and a most abundant bearer. There is no variety of Plum which can be depended on with so much certainty of a crop as this; there is never a season in which it does not bear one. It might be called frost-proof, its peculiarity, which at the same time is also a great recommendation, being that the flowers and the leaves expand at one time, so that the leaves, which are large, become in a great measure a protection to the flowers. There are seldom frosts severe enough to injure the young fruits which are thus protected. In the case of every other variety that I am acquainted with, the flowers open a good while in advance of the leaves, and so are quite unprotected for a time. The tree grows freely and to a tolerably good size; yet here again it is subject to another peculiarity—freak it might be called. It is this: The trees may have attained a good size and appear as healthy as need be; they blossom well, and there is every appearance of a good crop, when suddenly one or two droop their leaves, shrivel up, and die. No, not quite; for if left alone until next season the main stem or trunk will throw out some young shoots, which, when the entire dead top is taken off, will again grow up into a tree, thus showing that the cause of death—the death of the top at least—did not arise from any defective root action, the roots being quite sound and active. Mr. Dancer has numbers of trees going off in this way every year, yet he is totally unable to account for this result in any way. I myself have examined both the living and dying trees, and can assign no reason for its occurrence. There is no gumming, nor anything of that sort apparent, which would be likely to cause the mischief. *Apròpos* of this, a certain grower of this particular variety of Plum, the Prince of Wales, some two or three years ago sued a certain company for damages for having caused the death of several of his Plum trees, through the establishment of some works immediately adjoining, from which great quantities of smoke and other noxious gases were distributed. I believe the Plum grower gained his point; yet here, in Mr. Dancer's grounds, are the Prince of Wales Plum trees dying off in exactly the same manner, without, as Mr. Dancer says, the slightest suspicion of any such cause. Despite this drawback, it is a Plum which Mr. Dancer highly recommends, and I am able here to state that he has upwards of three hundred trees of it in cultivation.

The next Plum which I shall notice is Mitchelson's. It ought properly to have been mentioned first, as it is one of Mr. Dancer's "bringing out." It is cultivated very extensively at Little Sutton, and greatly valued. It is a rather small, roundish-oval, black Plum, somewhat like a Damson, but larger than that, and not quite so large as the Diamond, which it also sometimes resembles when well grown, as Mr. Dancer has it. Mr. Dancer grows a very great number of trees of this sort. There are lines upon lines of them from 10 to 20 and 30 feet high; and every tree this season, and for that matter every year, is a perfect sheet of black (there are more fruit than leaves), with the thickly clustered fruit. It is, indeed, a most prodigious bearer, and very valuable as a market Plum. A portion of Mr. Dancer's ground having been required by the new railway to Richmond, about two hundred of these Mitchelson's Plums were removed to other quarters two years ago. Almost every tree is growing, and many of them were well loaded with fruit. Plum trees bear removal very easily, and if unfruitful it is an excellent plan of inducing fertility. Mr. Dancer was the first to bring this Plum into such good repute as it now enjoys, and nobly he shows it off. Although a very profitable variety for the market gardener, it is not in my opinion so good in any way as Prince Englebert, which at first sight might pass for Mitchelson's. It is more oval in form, larger, and sweeter. Mitchelson's Plum usually ripens in the end of August; this year it was much earlier. It is often

confused with Ickworth Impératrice, from which it is totally distinct, the Ickworth Impératrice being quite a late Plum.

ROSE LORE.

A WHITE Rose seems to have been unknown to the ancients, and, indeed, until comparatively modern times, consequently from *Rodon*, ruddy, its Greek designation, almost all the nations of Europe have adopted a name of synonymous meaning. *Rosa*, its Latin designation, has the same reference to colour, and it is surprising—because without a parallel—that nearly every European nation has done likewise. In Anglo-Saxon it is *Rose*; in Welsh, *Rhos*; in Dutch, *Roos*; in German, *Rose*; in Danish, *Rose*; in Swedish, *Ros*; in Scotch, *Ros*; in French, *Rose*; in Italian, *Rosa*; in Spanish, *Rosal*; in Portuguese, *Roseira*; and in Russian, *Rosa*.

The unanimity characterising its nomenclature also characterises the high esteem in which it has always been held. It was the flower dedicated to Love and its birthgiver Beauty—to Cupid and Venus. The arrows of Cupid were said to be formed of Rose thorns, and his wings of its petals; he is always fresh, ruddy, and smiling, and his hair as golden as the flower's anthers. The flowers were said to have been created white from nectar spilled by Cupid at a banquet of the gods, but that blood from the foot of Venus as she rushed to the aid of Adonis fell on the petals and stained them permanently.

A deity to whom a flower was dedicated by mortals seems to have exercised the rights of ownership, and to have rededicated that flower to such as he or she deemed meriting the distinction, or even as a bribe. Thus, Cupid, like a dutiful son, dedicated the Rose to Harpocrates, the god of silence, to engage him not to betray the evil acts of his mother Venus. Hence it became the emblem of silence; was held up as a polite check to the loquacious, and was placed upon the guest table to intimate that the conversation around it was confidential. With a similar intent the Greeks also wore Roses at their feasts; *Comus*, deity of the table, and *Hebe* and *Ganymede*, nectar-bearers to the gods, were crowned with Roses.

"None, crown'd with Roses, drink the insipid spring;
No joy to mortals thin potatoes bring.
Bacchus loves flowers; to Bacchus garlands dear;
Witness the starry wreath on Ariadne's hair."—*Ovid*.

When arricular confession prevailed here, the English clergy were commonly a Rose, and it frequently was retained by them until about a century and a half since.

The Rose also was placed in the hand of one of the Graces, and wreathed the heads of two of the Muses, *Erato* and *Thalia*; it was also the emblem of youth, and sculptured on the tombs of the maiden dead. Even the tombs of all ages were decked with its flowers.

"When life's no more their odours shed
A grateful fragrance o'er the dead:
'Tis well, for when their charms decay,
And sinking, fading, die away,
Triumphant o'er the work of time,
They keep the fragrance of their prime."—*Anacreon*.

Even now in some parts of Wales it is customary to plant a white Rose upon a maiden's grave, and a red Rose on the grave of any one of noted excellence.

The Rose has always been preferred as the emblem of Beauty but it is also associated with effeminacy and voluptuousness. Gallienus, the Roman Emperor, justified this association by having in summer time a bed of Rose petals, and he, like *Smyndrides*, complained that a crease in one of them caused pain.

At Athens, early in May, at the festival of *Hymen*, the maidens and lads were crowned with Roses. Similar crowns were awarded to poets, and the Feast of Roses was one of the assemblies of the Troubadours.

Nor has the Rose escaped from association with superstition. In mediæval times the maiden gathered Roses on Midsummer eve,

"And bid it, for her shepherd's sake,
Await the new year's frolic wake—
When, faded, in its altered hue
She read, 'My lover is untrue.'
But if retained the crimson paint,
Her sick'ning hopes then ceas'd to faint."

It has been a custom for the popes annually to bless and perfume a Golden Rose tree, and to send it to some sovereign or other eminent person who has markedly served the cause of Romanism. The French Empress had it presented to her by the present pope. This ceremony of blessing the Golden Rose was instituted by Pope Leo IX., who was elected to the ponti-

estate in 1048. When the monastery of Saint Croix, in Alsace, was founded, he stipulated that the brethren should send to the pope yearly a Golden Rose. The ceremony of its presentation to and benediction by the pope takes place at Rome on the fourth Sunday in Lent. Our Edward I. was not only a Crusader, but so aided the popes in their Sicilian wars, and so sumptuously furnished their table with a golden service, that it is probable "the Golden Rose" was presented to him, and that consequently he adopted it as his badge. At all events, he was the first English monarch who adopted the Rose as a badge, and his was a golden Rose on a green stalk. The red Rose was first assumed by the Duke of Lancaster, John of Ghent (Gaunt as usually erroneously pronounced and spelt), in the reign of Edward III., but Henry IV. was the first of our kings to adopt that badge. Edward IV., among other badges, had the white Rose, and it was a white Rose *in sole!*—that is, surrounded by rays. The succeeding kings had the same badge, but Henry VII. had for his badges the white and red Rose joined. Henry VIII. had both the red Rose alone and the white and red Roses joined and crowned. Queen Anne Boleyn had a white crowned falcon, holding a sceptre in her right claw, perched on a golden trunk, which bore both white and red Roses. Catherine Parr had a maiden's head crowned, issuing out of a bush of white and red roses, very appropriate, considering the narrow escape from the executioner she had as Henry VIII.'s wife. Edward VI.'s badge was of red and white Roses combined. Mary had a red and white Rose and a Pomegranate, in compliment to her Spanish husband, knit together. Elizabeth had not only the red and white Roses, but many other devices. James I. had for his badge a demi Rose crown, impaled with a demi Thistle. Anne had the Rose and Thistle borne by one stem, and so had George I. Queen Victoria's badge is a red and white Rose united.—G.

BEET AS AN EARLY BEDDER.

I HAVE much pleasure in again replying to Mr. Robson's inquiries (see page 356), as to the merits of Beet for decorative purposes, and this time I will be a little more explicit than I was in my former article on the same subject.

The following is the treatment I adopted with it in the past season, and if Mr. Robson should feel disposed to give the same variety a trial under the same or similar treatment, I am sanguine enough to think that he will not be disappointed, and will find it equal to any of its competitors for early decoration.

The seed was sown in a shallow seed-pan in the middle of March and placed in a propagating house, where the pan remained until the plants were showing their second leaf from the seed leaf. They were then taken to a cool greenhouse where they remained in the seed-pan for about a fortnight, when they were pricked out into boxes and shallow pans at about 3 inches apart, and again placed in the greenhouse; there they were kept until finally planted out in the flower garden in the end of May, by which time they were good stiff plants 4 or 5 inches high.

In moving them out of the boxes and pans at planting-out time, care was taken to lift as much of the soil with the roots as possible so as to prevent flagging, and as the sun was rather powerful just at that time, I had them shaded for a few days, in the middle of the day, by placing a flower-pot, inverted, over each plant, so that the plants never received any sudden check to their growth, and I assure Mr. Robson that by the end of June they were in advance of *Perilla* planted out at the same time, and were quite in character with *Pelargoniums*, *Calceolarias*, and the other occupants of the flower garden. As with me early effect is of as great importance as late, I would not give the Beet the character I have done unless I had proved it to be good throughout the season.

Last season being the first I had ever used the Beet for decorative purposes, I had grave doubts about its continuing all the season without running to seed, through being sown so early, and in order to be prepared against anything of the kind occurring, I made a second sowing in May, so as to have a reserve to replace any plant that might "bolt," but I am happy to say that I did not require to fall back on the reserve stock, as not a single plant out of the early sowing went to seed, or showed any symptoms of doing so, and every plant was almost as uniform as if cast in one mould.

The soil of our flower beds is light but good. The only measure I ever apply to our flower beds is leaf mould, which I use rather freely, being no advocate for starving any occu-

plant of the garden if I can help it. I am also strongly in favour of a good depth of soil for the beds, finding that it snits either wet or dry seasons better than beds composed only of a few inches of soil. Most of our beds consist of from 18 inches to 2 feet deep of prepared soil.—JOHN MASON, *Prince's Park*.

SUBTROPICAL GARDENING IN THE NORTH.

NOTICING in your number, dated September 12th, page 357, an article on subtropical gardening, I send these few words to encourage others who may feel interested in this my favourite branch of horticulture. I may say that with care and attention, combined with a little study of the nature and habitat of the plants used, even the inhospitable north is capable of this style of gardening. I live in a bleak, exposed spot on a high table land in Wigtownshire, yet this year my first attempt had considerable success.

To speak briefly, I planted out beds of *Dracæna terminalis*, *Meranta fasciata* and *zehrina*, *Alocasia metallica* and *macro-rhiza variegata*, *Tradescantia discolor*; *Begonia Helène Uhder*, *Keramis*, *Marquis de St. Innocent*, *Adolphe Pollack*; *Caladiums Cannartii*, *Wightii*, and *picturatum*, among the smaller-growing plants. Among the larger there were Bananas (*Musa Cavendishii*), *Ferdinanda eminens*, *Solanums*, *Cordylone indivia*, *Latania borbonica*, *Sesforthis elegans*, *Wigandia caracasana*, *Monstera deliciosa*, Indian-rubber plants, several sorts of Cannas, Castor Oil plants, *Aralia papyrifera*, *Calla æthiopica*, and *Chamerops humilis*. These were all young plants, have done well, increased visibly in size while planted out, and are now taken up quite healthy to store up for next year. The only things to mar the effect were a little scorching on the lower leaves of the *Dracænas*, and some of the Cannas being exposed too much to the high winds prevalent in this part of the country; the foliage, however, was only a little damaged. Next year I hope still more to extend the collection. Should this be considered worth printing, I will give a more detailed account of my method of procedure at a future time.—GEORGE R. HARRIOTT, *Killimore Lodge, Kirkcowan, Wigtownshire*.

THE FLOWER BORDERS DURING LAST SUMMER.

LET me say a few words about our borders now that the summer is ended. I will begin with the Roses. With us they have been all that could be desired during the season. Pillar Roses have been forced upon us, owing to our exposure and suffering from the winds, which compelled us reluctantly to give up the cultivation of standard Roses. When they had attained any size we frequently found them in windy weather, in spite of all our watchfulness, sweeping a certain space, disfiguring all around them with dirt, and spoiling themselves for months, after all the care exercised to preserve them from the insects and diseases they are subject to.

The Crimson China Roses in beds have this season been remarkably fine, and a large bed of that fine old kind, *Géant des Batailles*, makes a display of no mean order; or, if thought desirable, one can have a splendid contrast by planting the centre of a bed with *Mrs. Bosanquet* or others of that class, then a belt of the *Géant*, with a ring of *Bourbon Queen*, or something of that kind, finishing with the *Crimson China Rose*.

For the borders we have adopted the pillar system. Our plan is to put in good strong poles or stakes 6 feet apart, then prepare the place to be planted by mixing the best loam we can obtain with well-rotted manure, charred refuse, and a little coarse sand, filling in the compost some time previous to planting in order to allow for settling. After planting we mulch as may be necessary, and we take up the plants every second or third year and renew the soil if requisite, keeping the plants secured to the stakes. We are well repaid for our labour in pursuing this mode of treatment, by the abundance and continuance of the beautiful flowers which are produced, and the roots are numerous and under control. During the past season the plants have been the admiration of all who have seen them, their rich foliage adding to the charms of their blossoms.

Most of our Roses are on the *Manetti* stock, the remainder on their own roots, which I much prefer. To enumerate anything like the collection would be quite foreign to my present intention, but I will name a few of the varieties which are doing good service as pillar Roses:—*Baronne Prévost*, *Colonel de Rougemont*, *Charles Lawson*, *Paul Perreae*, *Madame Hector*

Jacquin, Senateur Vaisse, Prince Camille de Rohan, Marie Portemer, Madame Vidot, Madame Laffay, Jules Margottin, Madame Bill, Madame Charles Crapetle, Victor Verdier. Monthly China, Madame Furtado, D'Aguesseau, Glory of France, Triomphe de Janssens, Chénédolé, Général Jacqueminot, Fulgens, Coupe d'Illéclé, Paul Ricant, Persian Yellow, Lælia, Comtesse Cécile de Chabrillant, La Reine (opened first-rate with us this season), Madame de Cambacérès, William Jesse, Dr. Ruscpler, Acidalie (a fine white Rose but rather shy-flowering; it requires to be kept stopped to make it branch and bloom), Devoniensis, Madame Willermoz, Niphotos, Isabella Grey, Lamarque, Triomphe de Rennes, Souvenir de Malmaison, Céline Forrester, Gloire de Dijon, Solfaterre, America, Rev. H. Dombrain, John Hopper, William Paul; and of Moss Roses, the Common, Cramoisis, and Laneii. Besides the preceding there are many others too numerous to mention.

Between each two Roses we plant such plants as Japanese and other Honeysuckles, Loasas, Tropæolums, Canary Creeper, Convolvuluses, and other tall-growing plants calculated to make a display in this department. The Hollyhocks with us, considering the season, have been remarkably fine.

Herbaceous plants have made ample compensation for our care. Many of this fine race of plants deserve far more extensive cultivation than they are at present receiving. I trust ere long to see them better cared for. I only intend to mention a few which have done us good service during the present year. There are among them some very interesting plants—for instance, *Morena persica*, *Aconitum versicolor* and autumnale, *Thalictrum aquilegifolium*, *Aster dumosus*, *Campnula Van Houttei*, or, as some call it, *Verschaffeltii*, *Ammobium alatum*, *Chelone barbata*, *Dieltamnus ruber* and *albus*, the Delphiniums (all fine border plants), *Dodecatheons*, *Echinops*, *Epilobiums*, *Eryngiums*, *Lathyrus*, *Linarias*, *Primulas*, *Veratrum*, *Yuccas*, *Antirrhinums*, *Brompton Stocks*, *Gynierium argenteum*, and other ornamental Grasses, *Astelina lanatum*, *Tritomas*, *Alstromerias*, *Gentians*, *Aubrietias*, *Sedums*, and *Saxifrages*.

Among annuals we have many very desirable plants for border decoration. African and French Marigolds have been very fine with us during the past season. China and other Asters have been of first-rate quality, not quite so large as in more favourable seasons, but really good. Stocks of various kinds have flowered well, and at the present time many of them are very fine indeed. *Callirhoe pedata* and others have been very beautiful. Double and single *Zinnias* have flowered well; they deserve more extensive cultivation.

Amaranthuses of various kinds have made a fine display, many of the *Silenes*, as *Silene compacta*, *rubella*, *pendula*, and *Schafti*, have been very fine. *Arctotis breviscapa*, a Gazania-like plant is a very fine flower; to bloom freely it should have poor soil. *Veronica syriaca*, a little gem, is of very dwarf habit, and now, from self-sown seed, is blooming freely. It succeeds well on rockwork, or in the border, and likes a shaded situation. *Viscaria oculata*, *splendens*, and others have flowered well; *Schizanthus pinnatus* and others have likewise been very fine; they require a little care in keeping them tied-up or well stopped, otherwise they suffer from wind. *Whitlavia grandiflora*, a fine, dwarf, border plant, succeeds well in most situations. *Sanvitalia procumbens* and its double variety are very desirable, being of neat dwarf habit; the latter is well adapted for dwarf edgings. *Acreolinum roseum* and others have succeeded well this season. *Salpiglossis atrococcinea*, *nana*, and *nana cærulea* are fine for borders, and have made an excellent display; they grow well in a moderately dry situation. *Phlox Drummondii* in named varieties has been fine with us. *Radewizi*, *Empress Eugénie*, and *Black Warrior* are the best; they make a first-rate bed. *Petunia phœnicea* answers well as an annual, either raised in pots or sown where it is intended to remain. *Pectis angustifolia* is a diminutive little fellow, but very pretty; it succeeds well at the base of the rockery or in a moderately dry border: it is rather subject to damp-off. *Nolana atriplicifolia* and *paradoxa* have been fine with us and flower a long time.

Oenothera Lamarckiana is a noble border plant, often attaining 4 feet in height, with large pale yellow blooms. It flourishes in most places. This plant ought to be more grown. *Oenothera bistorta Veitchii*, a very beautiful little plant, is tolerably well adapted for forming dwarf edgings; it is bright yellow and very showy. *Nigella hispanica*, a singular-looking plant, has been very fine during the summer. It has grown well in all places. *Nemophilas*, of various kinds, have been good with us. *Lavatera trimestris*, with large pink flowers, is a splendid

annual for borders. It is very distinct and beautiful, and grows well in any soil. *Kaulfussia amelloides* is a very dwarf-growing plant, makes a neat edging, but is not of very long duration. *Lupinus nanus* has flowered well this season; *Atrococcineus* is a splendid plant for borders, so is *hybridus Dunnetti*, *birsutus*, *albo-coccineus*, *roseus*, and *mutabilis versicolor*. We have during the past season had plants of the last-named 5 feet in height, and its variously-coloured flowers have been admired by all who have seen them; it is certainly one of the finest *Lupines* I have met with.

Linum grandiflorum stands high in my estimation both for beds and borders. *Loasa aurantiaca* and *Herberti* make fine border plants raised in frames, hardened-off, and planted in the borders. They are very attractive on account of their curious-formed flowers, but are rather unpleasant to handle. *Loasa lateritis* is very pretty, but virulent to handle. *Leptosiphon densiflorus* and *aureus*, are beautiful flowers; they will do for beds or borders. The *Ipomæas* are a splendid race of summer-flowering plants; raise them in pots, plant them where wanted, give them a support, and they require little more care. Their diversity of colour has a charming effect, either when they are mixed or grown separately.

The many varieties of *Helichrysum* are very useful, both for beds and borders; they have been very fine, and many of them are still so. They, as well as other Everlastings, are useful plants to cut for winter decoration. The *Gilias* are useful, and have done well this season. *Godetia bifrons* and *Lindleyana*, are good border flowers. *Gypsophila elegans* is a graceful little plant. *Dianthus Heddewigi*, *D. laciniatus*, and *D. dentatus*, have made a fine display during the summer, continuing a long time in bloom. *Clarkia grandiflora*, *Clarkia pulchella integrifolia*, and *pulchella alba* and *plena*, have been good. *Artemisia annua* is a tall-growing, graceful plant, by some persons considered rather desirable on account of its scent. Though of no great beauty, it is useful for bouquets. *Aster tenellus*, a pretty annual, has been much finer during the autumn than it was in the hot summer. *Athanasia annua* is a useful plant for either beds or borders; it continues in flower a long time, is very showy, and seems to succeed well in all places. *Calandrinia umbellata* is a little gem too little known; it has done well with us this season. *Bartonia aurea*, as a border plant, has been fine with us all the season. *Coreopsis tinctoria*, and other kinds, are a beautiful tribe; their diversity and richness of colour command general admiration. *Calendula Pongei*, and its double variety, are very desirable, and have been very good.

Alonsoa grandiflora, and others, succeed well as annuals. *Linaria bipartita*, and *bipartita splendens*, are very showy, and flourish in most situations. *Sedum cæruleum* has been very fine as a border plant; it likes a rather shady situation. *Salvia horminum purpurea* and *rubra* have done us good service, their red and purple tinges have some attraction at a distance. *Centaurea cyanus* is a very desirable plant as an annual. *Centaurea moschata*, and *moschata alba*, have made a fine show. *Brachycome iberidifolia* has done well in beds and borders; it can either be raised in pots, or sown where it is intended to remain; when well selected it is of a fine blue.

The imported German Larkspurs have been remarkably fine. I have often experienced some difficulty in keeping them after they come up; the slugs are very partial to them. I find it good practice to sow in pots, set these on ashes, and when the plants become strong to plant out. *Adonis æstivalis* is very fine, but of short duration. *Atriplex hortensis rubra*, a tall-growing red-leaved plant, is a conspicuous object at a distance; it has been very fine. Lord Anson's Pea, *Lathyrus magellanicus*, is a beautiful border plant, and deserves far more extensive cultivation. *Corydalis glauca* (sempervivens of some) is very handsome and hardy. I have sometimes seen it stand through the winter, and flower very early in the spring; it is then very fine.

Mesembryanthemum tricolor and *glaucom* have been very fine, the hot summer being all in their favour. *Helenium Douglasii* has been fine; this makes a good display early in spring when sown in autumn and kept through the winter. *Hibiscus africanus* has been good with us this season. *Cacalia coccinea* is a very fine border annual. *Eutoca viscidula* has done better with us this season than I ever remember. I have seen it go off all at once as if struck with some disease. *Centranthus macrostemon* is a good useful annual.

One of the best annuals we have is *Saponaria calabrica*. We have sometimes used it for bedding, and very fine it has been; it has played a very conspicuous part in the border at all times. *Malope grandiflora* is a fine border plant, and continues long in

bloom. *Chrysanthemum segetum*, though a native plant, is well worth a space in the border among other annuals. *Malva zebрина*, a tall-growing plant, is fine as a third or fourth row plant in the border, and is one of the most showy plants we have. *Cistus helianthus*, a splendid little fellow, should be sown in autumn, potted, and plunged in a cold pit; and planted in the spring, it makes a lovely bed for a short time.

Many other annuals might be enumerated, which give our borders a charm during the summer months, that nothing else can, and they are all the better of being transplanted and moved to their blooming positions with balls. They will repay any amount of care bestowed upon them.—M. H., *Acklam Hall, Middlesbrough-on-Tees*.

SUBTROPICAL GARDENING—PLANTS OF EASY CULTURE.

I QUITE agree with Mr. Williams, page 357, that subtropical gardening in its varied forms requires to be more freely discussed, so as to place it in its true light before those who may be anxious to try it. For this purpose it would be quite as useful to have fair statements of the cases of those who have made the attempt and failed, as of those who have done so and under favourable circumstances been successful. Unfortunately few are willing to do this, yet it ought to be done, as nothing is more instructive than failure when the mode of culture adopted is fully known; and as there have been many failures with subtropical gardening, it would be well to consider the whole question in all its bearings, and ascertain whether that branch of gardening is within the reach of many who now attempt it. As there are, doubtless, many persons who are anxious to do so, the plants most generally useful might with advantage be pointed out, and as these are both numerous and interesting, and can be grown by almost all having a hotbed, the observations on each will be plain and brief.

Before, however, entering on this matter, it may be said here, with all respect to those who have of late years done so much to place this description of gardening in the high position accorded to it by those devoted to ornamental plants, that it had its advocates in days long since gone by—certainly not to the extent it is at present practised, but still some of the plants now employed had been tried then, and not altogether without success, for I recollect that upwards of forty years since some little sensation was created by *Melianthus* major being grown and flowered out of doors about four hundred miles north of London. Ten years or so later found *Brugmansia* (then called *Datura*), arborea flowering likewise out of doors, and it is upwards of twenty-five years since I saw the first bed of *Cannas*; and I suppose the *Sedums*, *Saxifrages*, and *Sempervivums* were almost as plentiful thirty years ago as now, as succulent plants were more popular then than they have been since, but they were seldom turned out of doors. However, it must not for a moment be supposed that I wish to detract in the least from the merit due to Mr. Gibson and others who have done so much in bringing subtropical gardening before the public, only in cases where the means are scant annuals ought only to be used, and these give more diversity, and on the whole a more tropical aspect to the eye, than the more costly shrubby class, although the latter may be more robust in habit. Commencing, therefore, with plants of easy culture, we have the large family of *Solanums*, the *Castor Oil* plants, *Wigandia*, *Ferdinanda*, some *Aralias*, &c., as well as some hardy plants, to which sufficient justice has not yet been done.

RICINUS, or CASTOR OIL PLANTS.—These are of easy culture, as some plants here attained a height of upwards of 8 feet, though not sown until the middle of April, when single seeds were put into separate small pots, which were placed in an ordinary hotbed. The young plants were forwarded in heat and planted out by the third week in May, and no further attention was paid them than staking after some high winds about the beginning of September. There are several species and varieties, but those with the red and the green bark respectively are the best two. In the trade they are called *R. sanguineus*, *R. macrocarpus*, and *R. glaucus*; one of them has ripened seeds here this season. They ought to have a sunny but not windy situation. The past summer seems to have suited them exceedingly well, more so than it has done other plants of apparently kindred habit, as will be shown.

WIGANDIA CARACASANA.—Although seedlings of the present season attained the height of 6 or 7 feet, they never presented the large foliage which the plant did in 1865 and the following

two years, the absence of rain doubtless being the cause, and here we had not the means of artificially supplying them with water. It may, therefore, be inferred that this plant requires moisture as well as warmth, and, like the *Castor Oil*, a sunny but not windy situation. It is advisable to sow much earlier in the spring than is necessary for the *Castor Oil* plants, and even plants kept over the winter, by being sown about July in the preceding season, make the largest specimens; but as the plants, unless kept in a warm house, are not ornamental after the dark days commence, it would not be worth while for those whose room is limited to attempt their growth during the winter. This plant seems to like a good rich loam, and its broad ovate leaves, with the upper surface beautifully netted and indented, while the under surface is slightly stinging, especially in the young state, the immense size of its leaves, and its good habit, entitle it to a first place amongst out-door fine-foliaged plants; neither do its flowers, which it often produces, detract from its merits.

FERDINANDA EMINENS.—Although I have had this plant 12 feet high by keeping it through the winter, I am by no means fond of it. Its apparent resemblance in the distance to a patch of Jerusalem Artichokes gives it a common character, and I think it has lost ground elsewhere of late. It is easily raised from seed, but ought to be sown early in heat like the *Wigandia*, and kept growing till the proper planting-out time, which must not be too early, the end of May being quite soon enough.

CANNAS.—The great diversity there is in this family, and their graceful appearance, added to their easy culture, give them a claim possessed by nothing else in their way for a bed or a mass, but they are hardly so well suited for planting singly. They are much harder than is supposed. We have here two large beds that have stood the last two winters with only a slight covering of leaves, and this season I intend to deny them even this advantage, from noticing plants elsewhere that have stood without it. The varieties are endless, but in general a good dark-leaved and dark-stemmed variety, of which the *Canna nigricans* may be regarded as the type, is indispensable as one. Then there is a fine, broad-foliaged, green-leaved variety of dwarf habit that is also good; and I believe the tallest of all is a yellow-flowered species, rather deficient of foliage near the ground, but otherwise of striking habit. Generally *Cannas* do best in a dry soil which is plentifully supplied with moisture, and a circular or oval bed of a large size, with a mass of this plant as a centre, and an edging of other plants, forms an important feature in the dressed grounds.

TOBACCO is certainly more picturesque than *Ferdinanda*, independent of the interest that attaches to it. I believe the *Nicotiana wigandioides* has the most striking appearance, but I have not seen it in perfection. Tobacco ought not to be planted out until the 1st of June, and then let it be done in dry weather, otherwise the slugs will be sure to find the plants out. The middle of April is early enough to sow the seed, and the sowing ought to be made in a pan or box in a hotbed, and the plants pricked out, either into separate pots or into larger frames or boxes, to be forwarded and hardened-off in the usual way.

BRUGMANSIA ARBOREA and other varieties are not so easily obtained in quantity as plants that are reared annually from seeds; but the roots, like those of old *Scarlet Pelargoniums*, will endure being taken up in autumn and kept in a dry cellar during the winter, and can be brought on in spring in the same way. The fine foliage of this plant and its still more remarkable flowers, entitle it to much attention.

ARALIA SIEBOLDI.—Perhaps this plant ought not to be included, as it is an evergreen shrub of doubtful hardiness, but very desirable if it would succeed well out of doors; for its large, glossy green, deeply palmate leaves give it a very handsome appearance. However, it has not as yet been sufficiently tried in all situations to speak with certainty as to its hardiness, but it is a handsome conservatory plant.

As the above plants are principally given as examples of what may be had in most cases where a hotbed is at command, it is not to be inferred that the collector need stop there, for some of the *Solanums* are interesting, and they differ widely from each other; but as a class I have never admired them so much as others have done. *Solanum robustum* and *argenteum* are about the best, while some prefer *S. cabiliense* or *betaceum*. The Japan Maize is also an easily grown plant and looks well, as do some of the ordinary plain-leaved varieties. Then there is a host of hardy plants with foliage more or less remarkable, not the least so being the common *Globe Artichoke*, the *Cardoon*, some varieties of shiny-leaved *Rhubarb*, and other plants,

to which, of course, the term subtropical cannot be applied. But as this article is more to assist those of limited means than to suggest fresh subjects to those already conversant with the matter, plants more difficult of increase need not be mentioned here; neither is it necessary to enter upon the lower-growing class of plants, some of which become green when planted out, and consequently lose all beauty, which, however, is not the case with *Tradescantia zebrina*.

To mention Indianrubber plants, *Dracenas*, *Crotons*, *Marantas*, *Caladiums*, and other stove plants would only be tempting persons possessed of limited means to devote too much attention to a description of gardening which an adverse season would render a pitiable feature; and it is to be feared that the past unusually hot summer, which has favoured the growth of so many tender plants, may tempt some to extend their cultivation in another year, which, perhaps, may be diametrically the opposite of this in respect to the heat and sunshine, and disappointment will be the result.—JOHN ROBSON.

KEEPING APPLES FROM FROST.

Is it correct, that if pans of water are placed in a room where Apples are stored, they are never affected by frost? A dealer who purchases very largely for the markets, states it to be a fact.—L. B.

[There is no doubt that water in a room checks the temperature of that room falling below 32°, the freezing point of water, for the water in cooling, and in freezing, gives out heat. But when the water is frozen, and the temperature of the room is below the freezing point, it would not prevent the Apples being frozen.—EDS.]

THE USES AND MAKING OF CHARCOAL.

So extremely useful to the gardener is charcoal, that he can hardly be said to have all his necessities about him when it is absent. It is, first of all, invaluable as a manurial agent, there being few soils, or rather plants, which are not benefited by its application. Who has not noticed how lovingly the rootlets of a potted Strawberry twine round and hug the little bits of it which have been put within their reach? or how those of pot Vines which have been top-dressed with a rich compost in which some of it has been mixed, will, trout-like, come almost to the surface to grasp the savoury morsels?

As is well known, charcoal is carbon in a more or less impure state, and as carbon forms rather more than half of the constituent parts of woody fibre, it would at first sight appear obvious that plants will find in it abundance of wood-forming material ready for use; but those who peer into these curious subjects, and tell us what they see, say that before it can become vegetable food it must be turned into carbonic acid, and that charcoal under such circumstances as being simply mixed with soil is never so transformed, but remains insoluble though reduced to the finest powder. Its undoubted nutritive qualities are, notwithstanding, accounted for by its very slowly forming carbonic acid when buried in the soil; partly also by its chemical power of absorbing and retaining ammoniacal gas, as well as moisture, in its pores, thus making each piece a little pantry full of all the good things of vegetable life; but in whatever way it acts is not of much consequence so long as we reap the benefits.

Used as a mulching material, either in summer to prevent evaporation, or in autumn to keep in heat, it is most efficient, as it is one of the worst conductors of heat known; it has also the advantage over many other materials so used, of being not unsightly, and if roughly powdered, of being somewhat harrowing to the slimy sensibilities of our enemies, the snails. Strewed over the surface of the soil, and frequently renewed, it protects from damp such crops as Lettuce, Endive, Cauliflower, &c., wintering in frames; and sprinkled over boxes of *Pelargoniums* which have been stumped in, and are hibernating, *à la Fish*, in a dry loft, I have more than once seen it do good service. Being a powerful absorbent it acts as a trap for moisture, of which it is also very retentive, parting with it only at a high temperature, or on exposure to currents of dry air. Hence the ease with which gunpowder gets damp, and the difficulty of again thoroughly drying it.

Charcoal dust, and in an inferior degree both wood and peat ashes also, greatly assist the germination of small seeds, and the subsequent development of the young plants; and this, too, no doubt, results from their power of absorbing moisture. The

ploughing-in of peat ashes along with artificial manures, before sowing Turnips in dry weather, is sometimes practised by farmers in this part of the country, where, unfortunately, an unlimited supply is always to be had for the burning.

In the formation of Vine borders charcoal seems to be less employed now than it was some years ago, owing, perhaps, to the more liberal use of bones; but setting aside the question of expense, where it cannot be made at home, there can be little doubt about its being greatly superior to lime rubbish.

In making charcoal for any of these, or for potting purposes, where there is a choice, the lighter woods should be preferred for the simple reason that they are more porous, those of an opposite character being generally selected when it is to be used for fuel. The professional charcoal burner cuts the wood up into short lengths, and splitting these carefully into pieces of nearly equal thickness, piles them up in a conical form, each piece lying in a nearly horizontal position; but the whole of the work can be done in a rough-and-ready way with half the labour, something in the following manner:—Collect a lot of wood, rejecting nothing thicker than an ordinary arm, or that has not had its fibre destroyed by decay. Cut it into lengths varying from 3 to 7 or 8 feet, and, having fixed upon a suitable spot, proceed to build the kiln. In doing this, place first two or three bundles of dry Spruce branches where the centre of it is to be, over these put a barrowload of coals in such a way that any good hearth stoker will be sure of their igniting; then, beginning with the shortest lengths of wood, set them on their ends around, and leaning against the faggots and coals, and continue thus packing them closely together, and keeping the base within as small a circumference as possible, until the wood is all piled up. Two spaces filled with faggots, opposite each other, and communicating with the centre, must also be left. The next operation is to cover the whole, except the top, with thick turves or sods, and in most cases the procuring of these is the most difficult part of the business. Where there is a farm near the difficulty can be easily surmounted, by making the kiln in the corner of a pasture field, which has either just been, or is about to be ploughed; but if this cannot be done, and if there is no suitable place about the grounds or woods, then the next best place to select is somewhere in the vicinity of the rubbish-heap. Here the whilom glories of the flower garden will likely be rotting in cartloads, and they answer pretty well if put thickly on, although it does entail a little loss in manure.

When the heap has been fired, and after the coals are burnt, and it is found that the flames have entirely pervaded the heap, cover up the holes at both top and bottom, and continue to put on more turves or rubbish wherever the flame attempts to break out, as the less air we admit, the less ashes, and the more charcoal we shall have. When burnt out, cooling may be accelerated by throwing a few pailsful of water over the heap, but so as not to saturate the charcoal, which should be stored in a dry shed, and sifted into various sizes ready for use.—A. W. S. D. IRE GARDENER.

CHRYSANTHEMUMS.

MR. FORSYTH'S, BRUNSWICK NURSERY, STOKE NEWINGTON.—No one, probably, has been more successful than Mr. Forsyth as a cultivator of specimen plants of the *Chrysanthemum*, both large-flowering and Pompon; and the large, admirably grown and flowered specimens which he has exhibited so successfully at the various shows, have won for him a high reputation as well as many prizes. His show-house at present contains a large collection of the best varieties, some trained in the bush form, others as standards, and many more (massed in the centre of the house), in the usual manner for furnishing large blooms for exhibition. Ranged on the side shelves are the specimens trained in the roundish bush-form, and among them a plant of Mrs. George Rundle is especially remarkable for its fine growth and the abundance of its pure white flowers. Dr. Sharpe, crimson, another new variety of 1867, also forms very fine specimens, and among older kinds Christine, Golden Christine, and Annie Salter, all of which are well known, are represented by large plants in beautiful bloom.

Among new varieties of 1868, Bronze Jardin des Plantes and Princess Beatrice, the former bronzed orange, the latter, large, lilac tipped with blush, are especially worthy of note; also Mrs. Sharpe, pink with a silvery tinge, and Le Grand, rosy peach. Of the previous years' flowers the most noticeable besides those already referred to, are Fingal, very large and fine; Dr. Lindley; Lord Stanley, orange amber; Lady Tal-

fourd, rosy lilac with a silvery back; Yolande, and *Purpurea elegans*, purplish crimson, fine in colour though not so large as some.

In the general collection we noticed the following as the most conspicuous for their size, colours, and beauty—viz., Prince of Wales and Virgin Queen, magnificent, the one purplish violet, the other pure white, and nearly 5 inches across; John Salter; Prince Alfred; Queen of Whites, with some splendid blooms; General Bainbridge, Crimson Velvet, Cherub, Beverley, Golden Dr. Brock, Defiance, as a fine specimen; Lord Clyde, crimson; Lord Ranelagh, Rifleman, Sir G. Bowyer, Lady Hardinge, Hereward, Donald Beaton, Pandora, Prince Albert, Anaxo, Rev. J. Dix, Sam Weller, Jardin des Plantes, Antonelli, Countess of Granville, Raymond, St. Columba, golden amber; Yellow Perfection, Julie Lagravère, Oliver Cromwell, Mr. Wyness, and Golden Beverley.

In rear of the specimen plants on the side shelves before alluded to, Mr. Forsyth has a number of fine standard Pompons with stems about 3 feet high from the pot, and fine heads of bloom. The Pompons are well suited for this mode of training, and as grown and flowered by Mr. Forsyth, are very effective in the conservatory. Among the specimens trained in this manner were fine examples of Bob, crimson; White Trevenna, a remarkably free-blooming variety, and excellent for the purpose; Cedo Nulli and Lilac Cedo Nulli, of which the same may be said; Andromeda, Aurora Boréale, General Canrobert, Duruflet, and Lilac Gem. Several Anemone-flowered Pompons, are also grown in the same way. Among the newer Pompons, in addition to Little Gem, the most notable are Madge Wild-fire, red with golden tips; Little Creole, brownish orange; and St. Michael, golden yellow; and of older kinds Salamon, Mustapha, Florence, and Brown Cedo Nulli.

It may be added, that besides the show-house there are several others in which, in addition to the large stock of bedding plants which is annually produced, there are specimen *Chrysanthemums* in various stages of flowering, and in concluding we may mention that we saw in the seed-shop blooms of two seedlings which gained first-class certificates at Stoke Newington Show. These were raised by Mr. Morgan, of Plymouth, and are called Mr. Morgan and Mr. Everany. The former is of a delicate lilac, and the latter in the style of Oliver Cromwell, reddish chestnut, and golden tinged at the tips.

TEMPLE GARDENS.—In the garden of the Inner Temple, Mr. Broome, and in that of the Middle Temple, Mr. Dale, have as usual a good display, Mr. Broome's being by far the more extensive, and including excellent examples of nearly all the leading varieties. These, having been protected by an awning, have not suffered from the frost like the Pompons and others exposed in the beds, and have been inspected by thousands.

THE PERSIMMON TREE WANTS TO BE CIVILISED.

ALL over our vast domain, from Cape Cod to Florida Reefs, there flourishes in a sort of neglectful luxuriance a beautiful little tree, known as the Persimmon, or American Date Plum. The botanists, who are always fond of calling things by hard, outlandish names, name it the *Diospyros virginiana*, and tell us that it belongs to the family of plants known as the dicocious, meaning there by that there are two kinds of trees, one producing female and the other male flowers, both of which must be grown near together, in order to produce fruit.

The Persimmon tree grows from 30 to 60 feet high, is of graceful and symmetrical shape, has long, glossy, shining leaves, and when loaded with fruit, present a very handsome appearance. There seems to be a much larger number of sterile than of fertile trees, as they are found wild in the woods. This tree is not very dainty in respect to the soil on which it feeds. It is found on the moist borders of the Southern swamps, by the running streams of the Middle States, and on the high and rocky hills or a more northern latitude. It seems to love both the deep black soil of the American bottom, and the thin, gravelly earth of our hill sides. No American wild fruit, if we except the Strawberry, can adapt itself to so wide a range of latitude, or can flourish in such a variety of soils.

"Growing in valleys deep and fair,
And on the mountain high,
And in the silent wilderness,
Where no man passeth by."

In size, shape, flavour, and quality, the Persimmon varies as much as the Pear or Apple. On some trees it is scarcely larger than a Cherry, while on others it equals in size the largest

Plum. Scarcely two trees can be found, even in the same neighbourhood, that produce fruit of the same degree of excellence. Sometimes the fruit is so mellow at maturity that it is crushed by its own weight as it falls to the ground; at other times it will bear a large amount of pressure without injury. Its period of ripening, too, is almost as variable as that of any cultivated fruit.

As with the form, size, and period of ripening, so also the flavour of this fruit is wonderfully varied. Sometimes it is hardly fit to be eaten, even after the frost has exerted its influence to soften its astringency. Of such as this old Captain John Smith, of precious memory, must have tasted when he exclaimed, "It turneth the month awry with torment." So, too, it is likely that it was an unfrozen, unripe, and naturally very poor Persimmon that the Poor paddy tasted, and called on the Virgin for help, thinking he was poisoned. That there are varieties of this fruit whose disagreeable astringency not even the frost can remove, and other sorts that are insipid and almost lacking in the peculiar flavour of the Persimmon, is true; but then objections can be raised against every kind of uncultivated, and most kinds of cultivated fruits, taken as a class. It is also true that there are trees of this that produce fruit that is at once sweet, mellow, luscious and delicious.

The Persimmon is one of the most nutritious fruits that can anywhere be found. The fruit contains so much nitrogen, that carnivorous animals will devour it with relish. The opossum feasts on it during the latter part of autumn, as it ripens on the sunny slopes of Kentucky, and then rolls down like a butter ball. During the late war much use was made of Persimmons, as supplies of meat and grain were scanty; and before and since the war, the Persimmon has been highly prized all over the south. Persimmon beer in an old Virginian household, is what home-brewed is in the establishment of an English country gentleman. It is a beverage which unites all the excellencies of old wine, new cider, and fresh-drawn milk. It invigorates, but does not intoxicate.

In former times, in the old dominion, they made brandy of the Persimmon; but it was in the good old days of "pure nature and primeval innocence" when logwood was used to colour cloth, and before country druggists sold prussic acid. But Persimmon beer does not find a substitute; it is a southern institution that no plan of reconstruction will seek to change. The freedman now, as the bondman did of old, gathers the ripe Persimmons, mashes them with bran, dries and bakes the mass, and puts it by to brew beer from for use in the harvest or tobacco field.

A good article of vinegar, too can be made from Persimmons, by simply macerating them in warm water and leaving them to ferment, as you would cider or high wines. Doubtless a superior yeast could be made from Persimmons, judging from the great amount of nitrogen they contain; but we doubt if the experiment has ever been tried. Recently, while travelling among the mountains of Arkansas, we found the Persimmon cured in dry houses the same as Apples or Peaches, ready to be cooked for the table.

Now what we are going to say is, that a tree which is so promising as the Persimmon deserves to become civilised; and that its merits should be taken in charge by some of the enterprising horticulturists who have done so much for the Pear and Apple, which are not half so promising in their wild state.—(*Prairie Farmer*.)

[This fruit tree deserves in England a place under glass. It is no novelty, for Parkinson, in the reign of Queen Elizabeth, described and portrayed it, adding, "it hath not borne flowers or fruit in our country, but the fruit as it came to us was firm as a Date, and almost as sweet." Attention was drawn to it in 1854 by M. Morren, in the "*Belgique Horticole*," where there is a good coloured portrait of the fruit. It requires to be grown under glass, if ripe fruit is desired. This is round, terminated by a small and point, about the size of a small Medlar; skin orange-coloured. Like the Medlar, it requires to be kept until "luscious in decay," and is then quite a sweetmeat. Its flowers are yellow, opening in July, and the fruit is mature when the leaves fall in November.—*Eds.*]

PRIZES FOR BRITISH FERNS.

Few people are aware of the immense size some species will attain under cultivation, and as great interest is now taken in them, can we not, by offering tempting prizes, bring some of the finest-grown specimens before the public?

If a £10 10s. cup, with a second prize added, were offered for each of *Athyrium*, *Polystichum*, and *Lastrea*, I think some of our first amateur Fern growers would be induced to compete for the championship.

The prizes should be awarded to the (say six) largest and best-grown specimens, the varieties at the same time being good and distinct.

Could not such sums be raised by subscription, and the prizes be offered at one of the Royal Horticultural Society's Shows? I should be glad to contribute £1 ls. towards the *Athyrium* cup.—P.T.E.R.I.S.

ROOKS AND CROWS.

INSTEAD of answering "AN ALLOTMENT GARDENER" in our replies to correspondents, we will respond to his query. "Are rooks and crows injurers of growing crops?" by making a quotation from a lecture recently delivered by Mr. Scott Skirving to the members of the Haddingtonshire Farmers' Club.

"That rooks help themselves to the fruits of the earth, no one, least of all the naturalist, can deny. Has he not called him *Corvus frugilegus*, the fruit-gathering crow? So much for the evidence for the prosecution; now for the defence. The whole of these attacks are more easily guarded than those of any other bird. The rook is such a sensible person that he knows a ploughman in his furrow will do him no harm, but he gives an old man with a little gunpowder a very wide berth. Then, though he likes Potatoes and Corn, he is by no means obliged to subsist upon them. On the contrary, his usual, ordinary, daily food consists of worms, slugs, grubs, beetles, and insects of almost every description. I have opened and examined so many rooks that I think I may say that, taking all the year round, nine parts in ten of their food consist of insects. And what insects? The common black beetle, the parent of wireworm, the wireworm itself, the Crane fly, the parent of the grub, and multitudes of the grubs themselves—in fact, almost every one of the larger foes of the farmer. One most unfounded charge has often been brought against the rook, even by practical farmers. He has been charged with plucking up grass and Clover, and with pulling up young Turnips, just as the starling has been charged with plucking out the wool of sheep. In every case that the rook has plucked a blade of grass or pulled a Turnip, it was to destroy the insect that, as soon as it had ruined that plant, would have proceeded to attack and destroy another.

"Yes, I say, the rook does much more good than harm, but you may have too much of a good thing, and, therefore, care ought to be taken that his numbers are not allowed to be excessive in any one locality. It is a mistake to say of him that his natural enemies have been destroyed by man. I should like to hear the names of his natural enemies. He has put himself under the care and control of man in a way that no other wild bird has. He builds on the ancestral trees around his house, without attempt at concealment, and it is for man to say when he becomes too numerous. He is the useful servant of man, but a man may have too many useful servants. I think, considering that almost every rookery is open to juvenile sportsmen, there is not much fear of a too great increase of these birds, the best of all rural police. Talk of rat-catchers, rabbit-catchers, and mole-catchers (the last animal doing more good than harm, by the way): what are these persons compared to the early-rising crow? Perhaps few here ever heard a song dedicated to a crow, for, with all his excellences, I cannot call him musical; yet a true poet has shown himself a true observer of Nature also. Bailey, among the many odd songs he makes his characters sing in his wonderful poem of *Festus*, has one on the crow, of which I shall read a couple of verses:—

'The crow! the crow! the great black crow!
He cares not to meet us wherever we go;
He cares not for man, beast, friend, or foe,
For nothing will eat him, he well doth know—
What a comfort to feel like a great black crow!'

'The crow! the crow! the great black crow!
He loves the fat meadows—his taste is low;
He loves the fat grubs, and he dines in a row
With fifty fair consins all black as a Sloe—
Oh, it's jolly to fare like a great black crow!'

ENTOMOLOGICAL SOCIETY'S MEETING.

THE first meeting of the season was held in the rooms of the Linnean Society in Burlington House, the President, Mr. H. W. Bates, being in the chair. An extensive list of valuable publications added to the Society's library during the autumn recess was read, and thanks ordered to be given to the several donors. The Secretary also announced that two parts of the Society's Transactions had been published since the last meeting in July.

Mr. S. Stevens exhibited a fine specimen of *Sphinx celerio* captured hovering over *Verbenas* at Brighton on the 20th of September, also a remarkable variety of *Sterilia clathrata*, figured by Hübner as a distinct species, *immarata*, from the collection of M. Desvignes. Mr. Edwin Barclay exhibited a number of specimens of *Vanessa Urticeæ* and *Zygana filipendule* from the Isle of Wight, which were uniformly

much smaller in size than ordinary British specimens. The former, also, were more strongly marked with black.

A letter was read from Gunner Wilson, of the Royal Artillery Woolwich, describing a gynandromorphous specimen of *Lasioecampa Quercus*, in which the left half of the insect was masculine, and the right half feminine.

Mr. Davis exhibited a number of beautifully prepared caterpillars of Lepidopterous insects (which he makes for sale at very reasonable prices), and also stated that he had observed that *Sphinx Populi* and *ocellata* had been double-brooded during the past season. A letter requesting information and specimens of gulls and Gull Flies of various kinds was read from Messrs. Muller and Kidd; also on a species of *Oiketicus* and other Lepidoptera observed at Shanghai, in China, by Herr Schrader. Mr. Muller exhibited a box of Lepidoptera from New York, and Mr. Pryor specimens of the rare *Scoparia Zelleri* and *Agropyria picta* recently captured.

Letters were received from A. H. Haliday, Esq., noticing the forthcoming first part of the Transactions of the Entomological Society of Italy; also from Mr. Rowland Trimen, giving an account of a remarkable Cricket, found in gardens at Cape Town, having a gigantic-sized head, and belonging to the genus *Anastotoma*.

Mr. Briggs, of St. John's College, Oxford, exhibited specimens of a new British Moth, which has proved to be *Leucania albimaculata*, taken by himself and his brother at Folkestone on the 15th August and 5th October; and the Secretary exhibited a specimen which he had received from Woolwich as the "Musquitos," and which proved to be a species of *Chrysopa*!

The following memoirs were read:—Comments upon Mr. Baller's recently published Catalogue of *Satyridæ*, so far as relates to the South African species, by Mr. Rowland Trimen; Contributions to the Knowledge of European Trichoptera, by Robert McLachlan, Esq., F.L.S.; Further Descriptions of Exotic Heteromorous Coleoptera, by Mr. F. Bates.

GARDENING IN THE FAR WEST.—No. 1.

THE vast wildernesses of Canada and the States have required whole generations of toil for their subjugation; toil too exacting and constant to admit any of the beauties or enjoyments of decorative gardening, so that gardening as a fine art has there been lost. But a large extent of these regions is now thickly populated with independent cultivators of the soil, who own their lands free of claims or dues, and who emulate each other in improving and embellishing their homes. These forest-bred landowners live in fine houses, eat and drink, and wear of the best, and are in manners and habits genuine country gentlemen; but, bred in the courts of nature, and accustomed to cutting wide swathes, and working in a hasty way, they cannot condescend to take pains with trifling details, and it is a very rare thing to find a native American engaged in careful nursery work or gardening. It is too "pottering." "There is not enough to show for the time you have spent." Yet no people are readier to appreciate or applaud the fine results of the gardener's art and skill that are sometimes seen near the cities, or on exhibition at the fairs, and nowhere certainly is there greater want of his skill.

Green leaves and flowers in winter are wanted to solace the long months during which the whole scene is sheet snow, and when blasts prevail which nip everything above the snow line that is not of the very hardiest, window gardening and winter gardening generally are most desirable there. Fruit is wanted over vast sections, which are parched by wind, drained of moisture by its condensation on frozen mountains and plains; this dried air combining with severe spring frosts and hosts of summer insects to destroy the bud, the blossom, or the fruit itself. Yet when or where fruit escapes, the finest flavours and colours are developed under the clear sky and bright hot sunshine. At thousands of homes there are wanted carpets of thick grass, choice patterns of flowers, curtains of shrubbery, and canopies of shade. There are elegant and handsomely decorated houses, beautifully kept internally, but devoid of all suitable setting externally for want of knowing how to effect it, or because the effect cannot be seen and enjoyed at once.

English gardeners are often met there—some very successful—others, who do not happen to have a theoretical knowledge adequate to enable them to adapt their accustomed practice in the mild humid climate, yet high sunless latitude of the country of their birth, often fail sadly in everything but neatness of work, and being isolated, unless in large cities, they can learn only in the too slow and dear school of individual experience one lesson per annum.

German gardeners are mostly growers of vegetables, and do better; yet are often defeated by the peculiar, half-tropical rain drenches and droughts of the summers. French, mostly florists, few, and confined to the cities by their language and

their tastes, often succeed well. Their native climate is less dissimilar, their culture is more under glass, and they seldom go far from the humid mollifying air of the seaboard or the great lakes.

Notices of a few of the principal points of climate and other differences, and how they are met or evaded, may be useful to some of your readers who may choose to encounter difficulties for the sake of ultimately attaining an independent position for themselves, and a better provision for a family than old and crowded countries afford.—PENNSYLVANIA.

PEACH CULTIVATION.—No. 5.

MODE OF BEARING.—The fruit is borne on the shoots of the previous year. The shoot in the year previous to bearing produces leaves at every joint, singly, or in twos and threes, and in the axils of the leaves wood buds or fruit buds are formed. Fruit is also borne on spurs or short shoots closely studded with blossom buds, and having blossom buds at the extremity of each, and a growing point or wood bud which the blossom buds in a manner enclose.

Fig. 9.

Fig. 9 represents a mature shoot of the current year furnished with wood buds, *a*, and fruit buds, *b*. There are usually at the bases of such shoots two or three wood buds, and invariably a wood bud at the point.

Fig. 10 is a representation of a short shoot or long spur, having a few wood buds at the base, one at the extremity, *a*, and a majority of fruit buds, *b*.

Fig. 10.

Fig. 11.

Fig. 11 is a very short shoot, or spur proper, which is rather uncommon, except where close pinching is practised, this kind of spur being generally destroyed in the process of disbudding. It is seldom present when long pruning is practised. Such spurs rarely have any wood buds except that at the extremity (*a*), which is always one; all others are fruit buds.

Now, to comprehend the process of pruning, it is necessary not only to know the difference between the various fruit-producing shoots, but also the buds upon them; for if in pruning we cut back to a fruit bud no young shoot can proceed from it, and the shoot must die back to the nearest wood bud. The difference in the buds will be seen on reference to the accompanying figures. The wood buds, *a*, have a pointed conical form, and consist of scales enclosing a growing point. They are generally solitary, except in the case of young trees, or situated by the side of a fruit bud, when the buds are called double, as at 1, *fig. 9*, or between two fruit buds, when they are termed triple buds, as at 2, *fig. 9*. The fruit buds are more plump and less pointed than the wood buds, still ovate, but in or after February they become globular, and, as they unfold, hoary. They are sometimes single, occasionally double, when one may be a wood bud, or both fruit buds, and in old trees there are occasionally three blossom buds together, but generally the triple buds have two fruit buds with a wood bud between them.

In young trees, wood buds in general are chiefly produced; in older trees, or those of considerable proportions, the disposition is to produce a majority of fruit buds, and without pruning they become too numerous, hence the necessity for pruning so as to promote the production of young shoots, and maintain the vigour and fertility of the tree.

PRUNING.—The Peach and Nectarine require winter and summer pruning. Winter pruning is best performed as soon as the leaves have fallen; but some advocate its being deferred until the buds have begun to swell, on the ground that they are then distinguished with greater certainty. Winter pruning may, however, be performed at any season, from the fall of the leaf until the rising of the sap, but not in frosty weather, for to cut and handle the shoots when frozen is a false economy of labour, and leads to gumming, and the dying back of the shoots

operated on. I can see no advantage in pruning and nailing trees in periods of severe frost, and doing so is a needless trial of man's power of enduring cold. Summer pruning will commence with the pushing of the shoots, and may be continued as required throughout the summer.

From the principal branches, shoots for bearing must annually be allowed to proceed. The extremities of these shoots in our climate are not generally sufficiently ripened, and that is the principal reason why they should be shortened, it being well in the first instance to proceed by stopping, and then shorten back to a wood bud. *Figs. 1 to 8 inclusive*, show the training of the principal and secondary branches, and the origination of the bearing wood, and the directions for pruning will be understood on reference to *Figs. 9, 10, and 11*, in which the wood and fruit buds are shown. It would be wrong to cut where the bar is on the shoot, *fig. 9*, for beneath that is a fruit bud, which would not produce a shoot, and if the blossom produced a fruit, the latter would fall, and the shoot die back to the nearest wood bud or shoot. The shoot should be shortened to any of the joints where there is a wood bud. If it be required for extension, or be the extension of a branch, it should be cut to a bud on the side next the wall, as in that case it will proceed straight; but if the bud is situated on the front, the shoot from the bud will curve outwards, or if on the side it will curve sideways. The shoot, *fig. 10*, has but three wood buds, two at the base, and one at the apex. In pruning, it must be cut above the wood buds at the base, or left its entire length. If not pruned it would in the following year be naked, but no doubt give fruit, and might then be pruned to the wood buds at the base where the bar is, and shoots would proceed from it in the following year. If cut to the wood buds before it produces fruit, a successional shoot will be gained, it being desirable to keep up the number of such shoots, and if they are not required they may be stopped and treated as spurs.

On reference to *fig. 4* (page 267), it will be seen we have main branches, and secondary branches from them, and that on these the bearing shoots are produced, the tree bearing on the shoots and natural and artificial spurs of the previous year. In *fig. 8* (page 303), the fruit is produced on the shoots of the previous year only, there being no spurs, but shoots only, and on the upper as well as under sides of the branches. *Figs. 1 to 4* are intended to represent the short-pruning system, in which summer pruning and stopping act a most important part, these operations, in my opinion, having a powerful effect in thoroughly ripening the wood, securing an equal distribution of the sap, maintaining an equality of vigour in the several parts of the tree, and completely preventing the sun-burning of the stem and branches. By sun burning the sap is arrested, and the branches become enfeebled and die off; but this evil is prevented by the foliage of the spurs and short stubby shoots affording the necessary shade from the powerful rays of the sun. It is not the short-pruning system advocated by some, which, however well it may answer under glass, and in a warm climate, is not according to my experience adapted for trees against walls in our climate.

We have seen how to train the trees, how to originate the branches producing bearing wood, or from which it is originated, and I will now endeavour to explain its management, taking the tree shown from *figs. 1 to 4* (see pages 266 and 267).

Fig. 12.

Fig. 12 shows part of a branch after the fall of the leaf, *a* being a bearing shoot which in summer had been stopped when it had grown 10 inches, or not more than 1 foot. Laterals will result from the stopping; these are to be stopped when they have made one or two leaves, and as they push again stop them at the first leaf. The laterals chiefly pushing just below where the shoot was stopped lower down, a sufficiency of fruit and wood buds will be formed. This shoot at the winter pruning should be cut back to a wood bud, either by itself or best when it has fruit buds at its side. This shortening will do away with the cluster of laterals at the top, as shown by the

bar across the shoot *a*, it being left about 8 inches in length, more or less as the buds determine; and by the shortening, whilst the shoot produces fruit in the following year, a successional shoot from its base will be originated as shown by the dotted line. That shoot, or another of the same year, of production, is to be stopped as its predecessor *a*, and at the winter pruning shortened or cut back to a wood bud.

The shoot *a*, in addition to the shoot from its base, will push from all the wood buds. These will not all be required; part must be removed, but only those having no fruit at their bases. The terminal young shoot from *a*, which I will for explanation transfer to *c*, should be retained and allowed to grow until the lower leaves are nearly full-sized, then shorten it to 3 inches. The other young shoots with fruit at their bases should be stopped when they have formed three leaves; all others are to be rubbed off in disbudding, always excepting the young shoot from the base of the bearing one, which is to furnish fruit the following year. Upon thinning the fruit it will be found that there will be some of the shoots stopped with no fruit at their base; these may be removed, but leaves must be preserved on the bearing shoot above the fruit. If the shoots on the bearing wood push laterals, take out their point at the first leaf after the first stopping. *c* Shows a shoot which has produced fruit. It will not do so again (except from the short stubs, which is not desirable), as we have a young shoot to replace it, and therefore it must in autumn or winter be cut off close to the successional shoot *b*.

The successional shoot *b* is to be cut back to the bar, or to 8 or 9 inches in length, and from its base a bearing shoot is to be originated and treated as its predecessor, which it will replace in the following year. As a rule, every bearing shoot should have a successional young shoot, and springing from the base of the bearing shoot, and as near thereto as possible. The successional shoots may be encouraged one year from the opposite side of the bearing shoots to that next the branch, and in the following year on the side next the branch. In this way they will be kept nearly in the same position, whilst if encouraged from one side only they become too close or too distant from the branch. Sometimes a bud will push from the stub closer to the branch than the origin of the last successional shoot; this should be encouraged and be made the successional shoot, and in this case the stub above may be cut off in the following autumn. This will keep the bearing wood close to the branch, which is desirable.

The long spur or short shoot *d*, fig. 12, may, if there is a deficiency of fruit buds, be left its entire length—that is, if fruit is to be taken from it, and in autumn it should be cut back to the wood buds at its base if they have not pushed in the summer; but if they push, stop the shoots at the third leaf, and repeatedly afterwards to one leaf, and in autumn shorten them to two or three buds from their base, and they will form spurs. If there is a sufficient number of fruit buds on the bearing wood, then these long spurs should be cut back at the winter pruning to a wood bud at the base, where the bar is on *d*, fig. 12 and in fig. 10, and from it a shoot will push in the following spring; and it may be allowed to grow to replace the bearing wood if desirable and well situated, or it may be stopped at the third joint, and afterwards to one joint, cutting back at the winter pruning to three buds, and it will form spurs in the following year, or shoots, and probably afford fruit.

The spur or short stubby shoot, fig. 11, and *e*, fig. 12, having no wood buds except one at the extremity, must not be shortened at the winter or summer pruning, but must be left its entire length, and suffered to grow annually until its length becomes too great, then cut it back to the branch, within half an inch or so, for it is probable that a shoot may start from its base or from the branch whence the spur in the first instance originated.

We now come to the shoots that are stopped, and they include all shoots except the bearing wood and the short or natural spurs. In fig. 12, *f* is intended to represent one of these shoots stopped as it ought to be when it has made three leaves, and repeatedly pinched back to one leaf after the first stopping. If it should not grow more than an inch do not stop it, but leave it entire; it is a natural spur. It requires some experience to distinguish between a shoot that is a spur and a shoot on its first appearance; but the spurs are in general much weaker-growing than the shoots, and have the leaves very close together, whilst on a shoot the leaves or joints are more than twice the distance from each other that they are on the spurs.

The shoot may not push after stopping; in that case it will form blossom buds in the axils of the leaves, and the object of the stopping is secured for it is a spur. If it push, for which we have already provided the needful stopping, buds, and more or less of them blossom buds, will be formed at the bases of the laterals, and below them blossom buds may have formed. In case of there being blossom buds below the laterals, the shoot should be cut to the next wood bud below the starting of the laterals, where the bar is across *f*, fig. 12; but if there are no blossom buds on the part left, or below the laterals, as will be the case if the shoot be strong, there will, no doubt, be some near the bases of the laterals. Instead, therefore, of shortening at the winter pruning to below the laterals, we must shorten the lateral or laterals to a wood bud having fruit buds by its side or immediately below it. It will be enough if from four to six fruit buds are left on each of the stopped shoots; but if this number cannot be secured without great length of shoot, it is better to rest satisfied with a less number, or with none, rather than have a long stub. In that case the shoot must be cut off below the laterals.

The pruning being upon the laterals, the shoots they produce in the following year must be pinched at the third joint if they grow more than an inch, and a shoot must be encouraged from the base (see dotted line *g*, fig. 12), and it will be stopped at the third leaf, and repeatedly to one afterwards. This will in winter be shortened to the nearest wood bud at its base, and all others shortened to two or three joints. If the spur, however, is long already, and shade the bearing wood and spurs, it will be well to cut the spurs off, leaving none but that which originates from the base, which is to replace them when they become too long and unmanageable. In general these spurs will need to be replaced every third year, so that a successional one must be originated in the following season from near the base, and held in reserve, one or more of these successional being secured according to the duration of the original spur.

The spurs must be kept short, and as near the wall as possible, and for the most part originated on the lower side of the branches, where they will not shade the bearing wood, though where there is room they may be left on the upper side, and they will be a means of replacing any worn-out old bearing shoot, a shoot being encouraged from the base of the spur; and the part above the shoot being cut away, it will grow strongly. The strong foreright shoots should be stopped, and treated for spurs the same as those similarly treated on the under side of the branches, only they must be more closely pinched, and shortened at the winter pruning, and ought not to exceed 1½ inch in length. If the spurs become very twiggy they should be thinned, and when old and long they ought to be replaced by others from the branch or base of the spurs.

It should be borne in mind at all times of pinching, stopping, or pruning, that all wood of the Peach or Nectarine above one year old is of no use, except to support the parts that then or afterwards may bear fruit; care, therefore, should be taken to keep the old useless wood as near to the branches as possible, by encouraging a young shoot from the branches or bases of the bearing shoots or spurs, so that these, when old and long, may be replaced speedily and with certainty.—G. ABBEY.

POMOLOGICAL GLEANINGS.

A JAPANESE APRICOT.—“A few years since,” writes “T. R.,” “I received a variety of Apricot imported from Japan by the late M. Siebold, and named ‘Mumô.’ My attention was soon attracted to it by its early blossoming in the orchard house, once or twice towards the end of January, some five or six weeks before the earliest sorts now cultivated. I quite hoped it would prove a valuable assistant in producing something quite new among Apricots, as the tree could be retarded by placing it out of doors, so as to have flowers ready for crossing when the early varieties put forth their flowers in the house. As far as I recollect, it gave its first fruits in 1866; they ripened comparatively late, and were not at all promising. Thinking it might be the effect of that cool season, I waited, hoping for something better. Last spring my tree put forth an abundant crop of blossoms early in February; they were of a pale pink, and very ornamental. A good crop of fruit followed, which, owing to the hot weather, ripened well. They were yellow, and of the exact form of the fruit of the Common Sweet Almond, with the same pointed shape, but not so large, and they ripened about a fortnight after the Early Moorpark, thus destroying my anticipation of having an early sort to improve

our present race of Apricots. As to the flavour of this curious fruit, it is difficult to describe; it was acrid, acid, and nauseous, with hard tough flesh. As compared with our Apricots, it was something worse than an English Crab to a Ribston Pippin. It is just possible that this tree may be employed by the Japanese merely for ornament, and it is also possible that they may have a peculiar taste in Apricots, and enjoy the flavour of 'Mumé.'

— THE TANGIERINE ORANGE.—“This delicious little fruit is most worthy of culture for this reason: it ripens in October, and thus gives a succession of soft fruits when late Peaches have passed away. It requires constant gentle heat except in the hot weather of summer, and seems to succeed better if the pots are plunged in tan while it is in a state of fermentation, or placed on a heated surface in cocoa nut fibre. The trees bear much more abundantly when planted in a raised border in a house kept warm. In a border that is heated they bear still more freely. I have one little tree only 3 feet high, on which are six dozen of fruit. This is planted in a border 5 feet wide, in the centre of which are two 4-inch hot-water pipes lying on the ground nearly close together, and the border filled with a compost of two-thirds loam and one-third rotten manure from an old hotbed. The gentle warmth given to the border by these two pipes is most favourable to their growth and fertility of the trees, for they seem to grow all the year.

“A house 30 feet long, 14 feet wide, and 6 feet high at its sides, with two borders 5 feet wide, heated as above described, and two additional 4-inch pipes on each side to warm the surface air in autumn, winter, and spring, as in my house, would give bushels of Oranges, not only of Tangerines, but of Maltese Blood, and St. Michael's. My trees of these sorts are loaded with fine fruit, which, owing to the hot summer, are fast ripening. The trees stand on slates over the two 4-inch hot-water pipes, the pots plunged in cocoa-nut fibre. They bear very large fruit even in 8 or 10-inch pots.—T. R.”

— DOYENNÉ DU COMICE PEAR.—Out of twenty-three dishes of Pears exhibited at the meeting of the Fruit Committee on the 17th inst, many of them of great excellence, this new variety carried off the highest honour, the first prize being unanimously awarded to it as the best-flavoured Pear exhibited, beating in that respect all our well-known good Pears which were pitted against it, such as Winter Nelis, Passe Colmar, Glon Morcean, &c. This is the third season in succession that this handsome variety has received the same signal honour. Twice, the present season and the last, it has been exhibited by the same cultivator, Mr. John Garland, gardener to Sir T. D. Acland, Bart., Killerton, near Exeter, and the year previous from the Society's Garden, Chiswick. This is sufficient distinction to stamp Doyenné du Comice as a first-rate late autumnal Pear. It is of large size, one of Mr. Garland's specimens weighing 15½ ozs. The flesh is beautifully white, delicate, and buttery, of a very rich and pleasant flavour. We do not know of any Pear that can be more highly recommended for general cultivation than this. It succeeds admirably as a pyramid on the Quince stock, in the neighbourhood of London, and it appears to do equally well in Devonshire, a county not very celebrated for the production of fine Pears. The fruit which Mr. Garland exhibited were grown on a pyramidal tree on the Quince stock, in a border much exposed to the south-west winds, which are very powerful in that part of the county. The soil, a heavy fresh loam, was specially prepared by Mr. Garland, the ordinary soil of the garden being of a worn-out character; subsoil loam, slightly mixed with gravel. Winter Nelis from the same exhibitor, grown on a south wall, in the same sort of soil, and equally exposed, was likewise of remarkably fine quality, and was awarded a special certificate.

CAMPANULA PYRAMIDALIS.

For a long time this was a fashionable plant, and adorned the halls of the nobility, and was frequently trained (as we have seen it in the north of Scotland) to cover the fire-place in summer. This Campanula is hardy, but its greatest beauty is developed in pot culture under glass; in greenhouse culture the flowers expand in such a marked degree compared with plants grown in the open border, that many assert that what is grown here in pots is a distinct variety from that grown in the open border; yet the plants are taken from the same stools, and the difference of flower is simply brought out by culture under glass. The outside plants have been in full flower for at least three months, and are now (Oct. 13) fairly covered with

fresh flowers from the ground to the height of 7 feet. The plants are sheltered by Rhododendrons, and growing in rich light earth.

The white variety of this Campanula we find rather more tender than the blue, but it is equally ornamental, perhaps more so, in pots. At Rothie, in Aberdeenshire, we remember having seen a border planted with the blue and white Campanula, and the effect was grand. This fine old plant is easily propagated by seed, or by division of the root; for common practice, division of the old stools will be found the most convenient. Stronger-flowering plants will be got from seedlings, but then it takes much longer time to get the plants into flower; it is generally the third year before good flower-stalks appear from seedlings. Suckers taken early in autumn, or good crowns, with ordinary care, will flower the following summer; every inch of the fleshy roots will grow into plants if put into a pot in light sandy soil; but seedlings are to be preferred to dormant eyes for good plants. To raise seedlings of this Campanula the seed should be sown under the same treatment that is given to half-hardy annuals, taking care that the seed is sown on the surface of the soil; the seed will grow in a cold frame, but not so surely. No finer old plant can be found for frame gardening; the young plants always do best in frames, and a frame is the best winter quarters for plants to flower the coming season; it is the previous season's growing that makes the fine pyramid of flowers. For pot culture small shifts are the best in the summer previous to flowering; flowering plants we shift early in spring into the pots in which they will flower, and water freely with liquid manure. A 12-inch pot will be sufficient for the largest-sized plant it can be wished to grow for greenhouse or conservatory. A free light rich soil should always be used in potting; in stiff soil the plants are apt to rot in pot culture.—CHAS. McDONALD (in *The Gardener*.)

THE COMMON BERBERRY.

I AM pleased that Mr. Robson has directed attention to this much-neglected shrub. I find from experience that it merits all he has said in its favour. Besides this there are many other berry-bearing shrubs—such as *Pernettyas*, *Berberis Darwinii*, and other kinds, *Arbutus*, &c., which are far too little planted. Considering the ornamental character of most of them, it is painful to the lover of beautiful shrubs to see the miserable specimens struggling for an existence in the most awkward positions it is possible to assign them, often overgrown by other shrubs and trees, and where there is not the shadow of a chance of their admirers ever seeing them in perfection.

We have the common Berberry largely planted here, and no shrub is better suited for a place in the front of shrubbery beds or borders, the pendent habit it acquires in this position is in pleasant contrast to the long-legged objects sometimes met with. Apart from its ornamental character, it is likewise used for garnishing fish and other viands where Parsley is used, and quantities of its fruit are here annually gathered and preserved for that purpose. I also use it daily for garnishing the dessert, small twigs of foliage and fruit mixed with dark green leaves have a lively appearance on the dinner-table.

Like most other plants the Berberry requires its favourite soil to bring it to perfection, and that soil appears to be a heavy rich loam, but if such does not naturally fall to its lot, it will accommodate itself to circumstances, and do fairly in any soil.

The *Arbutus*, too, is a highly ornamental evergreen shrub at this time of the year; it has fruited so abundantly with me that I could have gathered gallons of its berries this autumn. I sent a bunch of flowers and fruit to the Royal Horticultural Society's meeting on the 17th of this month, but no notice was taken of it, so I presume its fruiting is so general this season as not to be worth mention.—THOMAS RECORD, *Lillesden, Hawkhurst*.

NOTES AND GLEANINGS.

We regret, and all who knew him will regret, to hear of the death of the REV. ROBERT PULLEIN, Rector of Kirby Wisk, near Thirsk. He has for many years acted ably as one of the Judges at the Birmingham Poultry Show.

— HER MAJESTY has presented to the LINDLEY LIBRARY of the Royal Horticultural Society, Dr. Roxburgh's "Plants of the

Coromandel Coast," and Sir W. Hooker's "Filices Exoticae," splendidly bound, and the presentation duly recorded on the binding.

— It is intended to hold an "INTERNATIONAL HORTICULTURAL AND FLORICULTURAL EXHIBITION" AT HAMBURG early in the September of next year. Prizes are to be given for Cultivated Vegetables, Fruits, Flowers, Garden Buildings and Appliances, and for Seeds and other articles. The proposed site for the Exhibition is in a park on a bank of the Elbe. The guarantee fund has been satisfactorily arranged, and a Committee formed, who promise ere long to publish full details. Exhibitors will be invited from all Europe, America, and elsewhere. Dr. C. H. Merck has been appointed Chairman of the Committee; Senator C. De Chapeaurouge its Vice-Chairman, and Mr. E. L. Behrens, Treasurer.

All communications should be addressed to Dr. Donnenberg and Dr. Göze, Advocates, Hohe Bleichen, 16, Hamburg.

WORK FOR THE WEEK.

KITCHEN GARDEN.

Artichokes (Globe), protect the roots for the winter. *Asparagus*, examine that in frames. *Celery*, earth-up when you can, and dig, trench, or ridge all vacant ground. *Cauliflowers*, *Endive*, *Lettuce*, *Radishes*, and small *Salading* will be quite safe where they are in pits or frames, as there is little difficulty in protecting them from such circumstances. Although we do not yet expect much severe weather, no time should be lost in securing plenty of *Endive*, and *Cauliflowers* of the June and July sowings, to be protected with straw or reed covers in turf pits. In making these covers, take three slips of wood, from 2 to 2½ inches broad, and from one-half to three-quarters of an inch thick, according to the intended length and width of the cover; put two pieces for the sides of the cover at the distance of from 3 to 4 feet apart, and the third in the middle, between the two; nail pieces of wood of similar thickness across the two ends, and in the intervening space use lighter wood at the distance of from 1 foot to 1½ foot apart: turn the frame of wood thus formed, and fill it neatly with reeds or straw to the thickness of the three longitudinal pieces, then nail on slips of wood opposite to those on the other side, cut the ends of the straw, and the cover is fit either for turf pits or glass frames. The using lighter wood for the cross pieces in the middle is for the purpose of causing less strain to be placed on the longitudinal pieces when moving the covers, also for rendering these lighter. Wheat straw is preferable to reeds, as being less expensive and not so liable to break when exposed to frost and wet alternately; but the straw ought to be drawn before the crop is threshed, and all the ears cut off, otherwise it will be bruised by the flail or machine, and the ears will not only act like a sponge in retaining moisture, but will offer an inducement to birds to pull the covers to pieces. Such covers are not quite so effectual in excluding rain as painted canvas, glazed calico, &c., but they are a valuable protection from frost, are inexpensive where straw is to be had, and afford employment to labourers in unfavourable weather. *Rhubarb* and *Seakale*, the most economical method of growing the latter is to sow every year and take up and force it when of sufficient size. Those who depend on beds out of doors for the first supply must examine the state of their fermenting material, to see that it is not becoming overheated; nothing is better than tree leaves alone. Those who desire a tolerably early supply with little trouble should cover their beds with any litter they can procure, so as to prevent the escape of the heat now existing in the soil. You must not overlook the *Spring Broccoli*. The plants have been growing luxuriantly all along, and although they seldom suffer from frost until January, they had better now or very soon be inclined with their heads towards the north. Whether it is from the check they thus receive, or from being less exposed, or from both, they are much safer in this way than left upright.

FRUIT GARDEN.

Those who find that the leaves of their Peach trees are still in a green adherent state, had better protect the trees slightly by means of straw-ropes, netting, or sticking fern, &c., among the branches, as a sudden check to growth after such mild weather would be more prejudicial now than after the trees had become accustomed to variations of temperature. In a garden in this neighbourhood I have seen some Currant trees trained with clean stems 4 feet high, and their tops

looked like the heads of standard Roses. When the bushes are pruned about this time short cuttings are made of the middle part of the shoots, with only two eyes at top, and are planted in a rich bed in a shaded place, and watered well in the summer. Some of them will be long enough for standards the first season, and all of them in the following one. The reason for discarding the bottom of the shoots is, that many latent eyes are formed there which cannot be seen and picked out, but which would push afterwards as suckers. Two eyes are to be left in case one should fail, but only the strongest shoot is to be allowed to grow, and the cutting ought to be short, so that the shoot may grow from the surface of the ground, and thus look clean and straight all the way up, which could not be the case if the cutting were far out of the ground, because the young shoot would form a "knee" with the top of the cutting.

FLOWER GARDEN.

As the leaves are now all in a great measure off the trees, the pruning of common shrubs may be proceeded with, and the border put in order for the season. As the ground must be cleared of leaves, it is best, when they are not wanted for other purposes, to draw them into ridges in the back part of the shrubbery, and there to let them rot, to be distributed over the ground about this time twelvemonth. It is not a bad plan to fill holes intended for American and other choice plants with wet leaves, and to place the ball level with the surface of the ground; as the leaves decay, the plant will sink to its proper level and grow admirably.

GREENHOUSE AND CONSERVATORY.

The earliest of the *Chrysanthemums* will now be nearly over, and when they are turned out the best way is not to cut them down, as is generally done, but to store them in light dry soil under a west wall, turned out of the pots; the tops being left on will keep the suckers more backward, and also shelter them in some measure. The less the suckers grow before March the better plants they will make next year. Spring-forced *Camellias* now in bloom should be guarded against currents of cold air and damp. *Cinerarias*, which are great ornaments for the conservatory in winter, are thirsty plants, and good subjects on which to try experiments with some of the new fertilisers, mixed with the water given them; they are also liable to the attacks of insects, which, unless looked after, will soon establish themselves among other plants. The fine large varieties of the Chinese *Primrose*, although they grow well near the glass, do best in shaded places where the sun cannot reach them. Two parts rough leaf mould, and one of very old cow dung, with a little sand, form the best compost for them, and in this they like plenty of moisture. Besides the double white and double pink, which are very showy at this season, there are sorts of all shades from pure white to very dark purple, and some with fringed edges, which look gay. The late mild foggy weather has been a trying time for delicate young plants, and sometimes fires have been in requisition for a few hours in the middle of the day. The double Roman *Narcissus* of the shops is the first of the forced bulbs to be in bloom in the conservatory; those who potted this and the *Hyacinth* early last August will in a few days see them in bloom. Cuttings taken off the tops of *Gesnera zebrina* after the flower buds were formed, are also now coming on to succeed the old plants, and, like cuttings of the *Hydrangea* similarly treated, flower almost as strongly as if left on the parent plant, and, as they stand dry heat, are excellent little ornaments to the sitting-room. Plants of *Euphorbia jacquiniiflora* cut down last January are now coming fairly into flower; they also stand dry heat, and will do in a sitting-room for two months. Moss Roses will soon be in; the mildness of the last two months was in their favour, as they dislike strong fire heat. This is the time to test the best stock to graft Roses on for forcing. Dog Roses make slow stocks compared with the old China or *Boursault*; but, of course, to begin in January or February to force Roses, they will do well enough on any stock and with little forcing.

STOVE.

The *Clerodendron splendens* prefers a cool shady part of the stove, and is better fitted for an intermediate house, but it will grow freely in a good conservatory if not allowed much light, which is disagreeable to it when growing. There is little doubt but that many other stove plants will prove sufficiently hardy to do in the conservatory, and this is the best time to begin the experiment. Look out duplicates, and place them by themselves to be kept drier through the winter than the rest of the

collection; they should also be placed in the coolest part of the house.—W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

LITTLE has been done here beyond securing crops that would be likely to suffer, as Lettuce, Endive, Radishes, and Cauliflowers. Banks of Coleworts, planted even more thickly than we stated, are coming in most useful. Cauliflowers out of doors had a bunch of sweet litter placed over the half-swelled crowns, with a broad leaf interposing between the litter and the head of the Cauliflower, so that the colour should not be injured.

Dwarf Kidney Beans have been sown in a mild heat and in small pots to occupy little room for the present, until they are planted out in masses to take the place of those now bearing profusely. We always think that Beans obtained in November and the first weeks of December are a very cheap and useful crop, as for their first stages they may stand out of doors with only a little protection, and we always think that a Bean that has been grown under glass has a richness and crispness all its own if gathered and cooked whilst it is young and tender, which it seldom is when the pod shows the place where the young seed is swelling. It is best to have every pod crisp, and smooth and regular in outline from end to end. The little Newington Wonder makes a fine dish if its pods, when from 2 to 2½ inches long, are cooked whole, and then the gatherings are very abundant. It should be remembered by all beginners that one pod on a plant swelling its seeds will exhaust the plant more than a dozen where there is no appearance of the seeds swelling.

Seakale and *Rhubarb* are going on well in a very mild heat in the Mushroom house. We have earthed-up a third piece in the Mushroom house, and put in manure for a fourth piece. The first piece is just showing all over, but small at present, and therefore not to hurry it too much we have put more covering on our bed in the open shed, and treated it much as described lately in these notices. We are slightly troubled in the Mushroom house with condensed moisture falling on the bed we wish to bear, and if it continue we will suspend a mat or a cloth over the bed to receive the drip and throw it off the bed. Though the Mushroom rejoices in a moist atmosphere, it does not like this drip, and if the manure is at all fresh the coloured drip will disfigure the appearance of the Mushrooms. We would refer beginners to a short article that lately appeared on growing Mushrooms, with the help chiefly of horse droppings. We have used a great variety of materials down to stubble, as forming the chief portion of our beds, but we must vary the practice a little in proportion to the materials to be obtained. It is of little use saying, at the present day, "It can't be done." Attempts must be made with very unpromising materials, and they often, with a little thought, result extremely well.

Cucumbers.—A few lights of these in a pit are bearing too profusely, though we cut off numbers of the fruit to ease the plants. We expect such bearing will finish them about Christmas, and we have three lightsful of young plants, though strong, put out in large pots, so as to be more under control, and from these as yet we nip off every fruit as it appears, and if we make up our mind to keep them bearing through the winter, we will not allow a fruit to swell for some weeks. We in the country are often circumstanced quite differently from gardeners near town. Cucumbers are often useful for shooting parties, and whilst they would be most valued in spring in London, they are of little value to us. Our own idea is that what appears at table every day in the year, ceases to be valued, and a short cessation often heightens the enjoyment.

Leaf-collecting.—We have collected a good quantity of leaves, but not one-half of what we wish to have, and which we will only obtain if we have a few more calm days, as, if a high wind come, most of ours will be off to the valleys for miles round. A fortnight ago we expected to collect some loads from the pleasure grounds, but the part that was thickest was as thoroughly cleaned one morning, as if it had been carefully swept with a broom. We find fault with no kind of tree leaves—Ash, Elm, Beech, or Oak, all are acceptable; for though the first do not last long, they soon become a valuable vegetable mould, and they yield a good heat for many purposes. Beech and Oak leaves, however, are our favourites, and of the two, for lasting we prefer the Oak leaves. We have known Oak leaves yield a fine genial heat for a twelvemonth, and then all but the

sides, when turned over, continue to yield heat nearly as long again, especially if some fresh leaves be mixed with them. For present use it matters little how they are collected, and they are easiest managed in dull damp days. The damp will cause them to ferment and heat at once. When intended to be kept for some time, they should be collected dry, and be stored under cover; though when built in a round or oblong shape out of doors, and the top tapered like a stack, they will throw off the rains, and thus be dry for the most of their bulk. We have taken leaves from such heaps after eighteen months storage so fresh, crisp, and dry, that we had to sprinkle them with water when we wished them to ferment and yield a sweet heat. One great recommendation of the leaves is that the heat they yield is sweet and mild at once. With abundance of this material we can never be at a loss for a little sweet bottom heat.

Bottom heat used in moderation is one of the best means for insuring good results; for, as a rule, it will ever hold good, that it is well to excite the roots a little so as to have them in action before the buds are greatly excited. From an old rosery we mean to pot a lot of plants to produce early flowers, but we could not expect to succeed if we put the plants in a mild heat at first, as the buds would break before the roots were acting afresh to keep up the growth. If we plunge these pots in a mild heat of leaves out of doors, letting all the tops be exposed, we shall have fresh roots in the pots before the buds swell much, and then we can force them gently in the usual way. Some so treated last winter did better with us than Roses that stood in pots all the summer, and were brought gradually on without this bottom heat. In all such cases, forcing bulbs, exciting Strawberries, &c., it is important that the heat should not be too strong, ranging from 65° to 70° and 75°, and rarely above it. When we go to 80°, or higher, the plants should be well established, and balanced as respects roots and branches, and an equivalent, though a lower temperature, given to the branches. All plants, especially those fresh potted and intended to be brought in early, that is, less or more forced, will be the better of this mild bottom heat in the open air, whilst the tops are kept cool. Even when a frame is used, the coolness at the top should be secured, by air at back and front, except in the coldest weather.

FRUIT GARDEN.

The work has been very much the same as in previous weeks' notices, clearing the orchard houses of decayed foliage, fresh mulching Strawberries out of doors, planting, and commencing pruning; and we noted that the titmouse and the bullfinch have begun their unwelcome visits to Cherries and Gooseberries.

ORNAMENTAL DEPARTMENT.

The frost having left more wrecks of vegetation than were fair to look upon, much time has been taken up in removing the thickets of growth in beds, and heavy work it has been. The lawn, however, looks cheerful where the beds are cleaned, and the grass fresh swept and rolled. Where a weed appeared on the walks, it was pulled up; and hard swept and rolled, they looked clean and cheerful, as no leaves will now encumber them, unless they come from long distances. Most of the scarlet Pelargoniums that were taken up and left in sheds, have been pruned in and faggoted away as closely together as they could be placed in boxes and pots. Of *Calceolarias* we took up a few dozens with balls, potting them where growing, so that the ball should not fall off, as we want these for good-looking, early-flowering plants in spring. Took up lots of double Stocks, double and single Wallflowers, and placed them under glass in the orchard house, as these will force a little if so wanted, and flowers are valuable in spring, however humble they might be considered in summer.

Took up and potted *Lily of the Valley*, and boxed more, merely for the flowers. When a fine pot is wanted, only the large firm buds should be selected, and be closely packed, and if they receive a little bottom heat at first, with a cool atmosphere near the surface of the pot, they will come all the finer, though it will require the best of our home growth, to equal the patches that come over from the Low Countries along with the bulbs, which are such an advantage to us in the winter and spring. We have seen this *Lily of the Valley* become a perfect weed, almost as difficult to destroy as so much Couch Grass; we have also seen unavailing efforts made to grow it in some places, and believe that in many of these cases the failure was owing to mistaken kindness and attention. It seems to delight most in a firm loamy soil, and when it must be grown in a sandy or chalky soil, an additional proportion of sweet rotten manure

should be applied; and after planting, and the leaves begin to appear, the soil between the rows should be trodden or malleted so as to be tolerably firm, and then the mere surface kept scratched or stirred to prevent gapes and cracks. Making the soil firm where naturally loose, we imagine to be of great importance. This was first brought to our notice by a seeming accident, but just one of those little things that often teach us a useful lesson. All efforts to grow the plant in the well-stirred, pulverised border of a kitchen garden seemed next to futile, but some of the roots found their way into a hard old gravel walk, and there they did well, far excelling those with which so much trouble had been taken.

Put Roses established in pots, Deutzias, &c., in a mild heat. We do not notice that anything has gone wrong with us particularly, except a batch of cuttings of the brown Coleus, which we left too long in a cold pit, and which are now likely to die. We are sorry for this, as we shall be forced to give room for some old plants that otherwise we would have thrown away, but we must keep them for cuttings in spring. We have seen several times lately, that this plant may be kept in a temperature of from 40° to 45°, but we fear the times of such low temperatures must be short indeed. It would be safer at from 50° to 60°, as a general rule, with a fall only for short periods in cold weather.

Calceolaria cuttings in the cold pit are looking well, though not yet beginning to root. All the care, after pricking them out, which they have had, was slightly syringing them over about eleven o'clock in a bright sunny day, and shutting down the glasses. During mild nights left a little air on all night, in cold nights shut up closely, and in the very coldest sprinkled a little litter over the glass. In a dull muggy day left a little air at the top of the sashes all day, say a quarter of an inch of an opening. The object is to prevent the little cuttings being extended much upwards before, or even after, they root downwards. In dull, damp weather they have hardly been looked at for a week together, except for giving or taking away the little air afforded. Of course it would be bad policy to give air when the sun shines. The close, damp atmosphere then keeps the tops from flagging, and we prefer that the leaf of a cutting should never droop, instead of having to make it rise again after it has fallen. Unlike some other things, a little damp, and even cold if not at or below freezing point, will do little or no harm to a *Calceolaria*.

Through a little carelessness we have lost an old favourite of ours—*Calceolaria amplexicaulis*, but we must have it again, as its creamy yellow is extremely rich. We mention it for stating that it is the only *Calceolaria* we have tried that will not do with such rough treatment as we give the other kinds in a cold pit. After being struck it is better kept a little drier and warmer, not hot, in a house. To have this fine old sort splendid early in summer as well as late in autumn, the first shoots should not be stopped or shortened in the spring.

Turfing.—On making alterations we have had a considerable amount of this to do, though for certain reasons, as respects time, &c., some of the work was not done in the very best way. When old beds and groups are to be turfed, they must be well beaten, as well as levelled to the requisite sweep; but even then it will often happen that such places will not suit in a year or two with the turf spaces left between them. In many cases it is best in every way, where such beds are tolerably close together, to take off the intermediate spaces of turf, turn up the ground, level, and beat the whole, and then the turf will keep its uniform sweep for a long time.

What we wrote lately about autumn planting applies equally to autumn turfing. What is done now will rarely give any more trouble in watering, filling up cracks, shading, &c.; and there is another great advantage where turf must be carted from a distance, that thin turf, say from half to three-quarters of an inch in thickness, will be as ample now as turf 1 inch or 1½ inch in thickness in March and April. Where much turf is to be laid the men's knees should be kept off the damp ground. No beating or rolling will ever make amends for not properly levelling the ground at first.—R. F.

TRADE CATALOGUES RECEIVED.

W. Rollisson & Sons, Tooting, London, S.W.—*Descriptive Catalogue of Hardy and Orchard House Fruits.*

André Leroy, Angers.—*Descriptive Catalogue of Fruit and Ornamental Trees, Shrubs, &c.*

Louis Van Houtte, Ghent, Belgium.—*General Catalogue.*

COVENT GARDEN MARKET.—NOVEMBER 25.

THERE has been scarcely any alteration worth quoting. Supplies are ample. Great complaints are made of the quality of the bulk of the Potatoes coming in now. There are large arrivals of these both by rail and sea.

TO CORRESPONDENTS.

*. We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely* to *The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

MELADON.—"J. K." wishes to know the botanical name of a plant so-called, having "roots the same as the Ranunculus, and flowers between those of Anemone and Ranunculus, but larger."

PICKERING'S SEEDLING (W. H. C.).—The Apples have not come to our notice.

CHRYSANTHEMUMS (Mrs. Roberts).—You will see the names of the principal growers in our advertisement columns.

SALE OF FRUIT AND FLOWERS (J. B. C.).—Write to Messrs. Webber and Co., Central Avenue, Covent Garden Market.

SORGHUM TATARICUM (*Sorghum*).—It is worthless, and can only ripen here in very hot summers. Mr. Hullett, who persuaded purchasers that it is a novelty, is now awaiting trial on a charge of forgery.

ESPERIONE GRAPE (*One Fond of Vine Culture*).—It is a good Grape for ripening on an open wall. Berries quite round, dark purple, juicy, and sweet, yet briskly flavoured.

WHAT CONSTITUTES MANURES (*Roschud*).—The best answer we can give is the following extract from Johnson's "Science and Practice of Gardening." You can have the volume free by post from our office if you enclose forty postage stamps with your address. "Manures are derived from animals, vegetables, and minerals; they directly assist the growth of plants—firstly, by entering into their composition; secondly, by absorbing and retaining moisture from the atmosphere; thirdly, by absorbing the gases of the atmosphere; and, fourthly, by stimulating the vascular system of the plants. Manures approximately assist vegetation, firstly, by killing predatory vermin and weeds; secondly, by promoting the decomposition of stubborn organic remains in the soil; thirdly, by protecting plants from violent changes of temperature."

PROTECTION FOR FRAME (*Idem*).—The best materials for covering a two-light frame are Archangel mats, employing one thickness for a slight frost. Two thicknesses, and 6 inches in thickness of dry straw, will be required in very severe weather. You cannot have a charcoal fire or lamp in so small a compartment with safety, and you may ward off frost by putting the mats and straw over the lights, the sides of the frame being protected by ashes placed against them all round.

LIST OF ROSES (M. Rose).—William Griffiths and Gloire de Vitry are both show Roses, vigorous, and generally good. William Griffiths is the type of shape and of fair size. It has but one fault, in very hot weather it does not always retain its colour. I always consider this Rose, Madame Vidot, Madame Rivers, Guineoiseau, and Comtesse de Caille de

Chabillant to be the 'elegant extracts' of the rosery. Gloire de Vitry (here on its own roots), is a very fine Rose, and in the fall of the year like Lælia. I have not had any healthier, or that have done better than these plants. It is a very large Rose. Of the three crimson Roses you named, I prefer Lord Clive. Vainqueur is very handsome, but not a very good grower, nor full enough. With regard to white Roses, they are still 'desiderata.' Not one of those mentioned by you is full-sized except Queen Victoria, which is peach-tinted in the centre, and not always a free bloomer. Devonshire and Mrs. Bosanquet are the best of those named. I advise you to buy Souvenir (Fée), Mad. Willermoz (Tea), and, as you do not object to tint, re. Souvenir d'Elise (Tea). They are admirable. The first is as hardy as Hybrid Perpetual. My plants of it are still full of fine fat buds. The finest of the white Roses is Madame Zoultmann, a summer Rose. Mr. W. Paul says as a white Rose, Mlle. Bérthe Levêque is desirable. I strongly recommend you to buy the following crimson Roses, if you do not know or possess them, for they are superior to those you have named—viz., Charles Lefebvre, Semanté Vaisse, Alfred Colomb, Antoine Ducher, Morchal Vaillant, Madame Bonfin, Madame Victor Verdier, and Pierre Notting, the finest of all the globular Roses. These are all excellent in every respect.—W. F. RADCLIFFE.

MULCHING OVER THE ROOTS OF ROSES—ROSE CUTTINGS (W.).—"You need not fear the mulching rotting your Roses, though it touch the shoots. If you see danger lift the mulching with a fork. I have mulched all mine, nearly 190 plants, and put a little earth over the mulchlog, and have tied up lightly with Asparagus haulm and fern all my yellow Roses. The lofty yellow Roses on my south front have sheepshuddles leaning endways against them, in addition to the mulching. I look for sharp weather between this and February 1st. Bottom heat would assist the Rose cuttings to strike. They are deceptive, they will often look as if they had roots, and yet will be found to have none, and die away in March. Put your cuttings in the earth in September and mulch them; many of them will make roots without trouble. Do not move the cuttings, but sink the pots in the earth in the spring. By the autumn they will have good roots. For cuttings, pieces of hard wood with a heel are the best; or wood of the current year with a bit of old wood. It is too late to strike cuttings now without bottom heat.—W. F. RADCLIFFE."

NAMES OF FLOWERS.—1, Love-in-idleness, is the Pansy; 2, Cuckoobuds, uncertain, perhaps the common Buttercup; 3, Dead men's-fingers, is *Orchis mascula*; 4, Crow-flowers, both the Buttercup and Ragged Robin, *Lychnis flos-enculi*; 5, Sweet Moly, *Allium moschatum*; 6, Kiss-me-at-the-garden-gate, another of the many names of the Pansy.

MAKING A VINE BORDER (A. S.).—It is well to cover an outside Vine border with dry litter at least a month before commencing forcing. If the manure heat a little all the better; but if it or litter be laid on from 15 inches thick before the earth becomes cooled, the heating afterwards is of less importance. There are several works on "Taxidermy." Any bookseller could tell the names and prices.

VINE LEAVES FALLING (J. F. C.).—Although the colour of the falling leaves of some young Vines is yellowish brown, and of one clearly red, still we do not think that it is certain that it is a different variety. We so say because the great heat of last summer has caused singular variations in the colour of the falling leaves of Vines. You must wait until they have fruited before you can be certain that your Vines are not all alike.

TRAINING VINES (Boston).—We would prefer single stems of Vines 3 feet 8 inches apart for general purposes, and where subsidiary crops had to be grown. But if the house were to be given up to Vines alone, then you might have two stems in that space, and would obtain rather more fruit in consequence in the same space. We have no doubt that the Royal Champion, Royal Ascot, and Pince's Black Muscat will do in the same house, but we cannot speak practically on the subject.

GLANDS OF PEACH TREES—PEACHES FALLING (C. R.).—Glands are small, generally wart-like swellings, found on the surface of plants and on different parts of leaves, and are mostly visible to the naked eye, though greatly varying in size. Thus, so far as Peaches and Nectarines are concerned, you will find kinds, the leaves of which are serrated; but beyond that, you will find others, perhaps not so deeply serrated, but especially near the base of the leaf and close to these serrations you will find little globe-shaped glands, or little protuberances. In other kinds you will find these little wart-like glands of a reniform or kidney shape. Sometimes they are so small that you can scarcely distinguish at first the shape of the glands, and in that case must examine a number of leaves instead of one. So much for Peaches. The size and form of glands in many other plants are extremely various. For a Peach to come in before the Royal George, have Early Grosse Mignonne. To begin to come in after the Royal George is over, have Walburton Admirable. The Royal George is not peculiarly liable to drop some of its fruit when nearly ripe. All stone fruit is liable to do the same when overcropped, or too little or too much water is given. In fact, a fruit or two will drop at times, and no particular reason can be assigned. We think it very likely you have the right kind. We do not think the Mountain Ash is much used as a stock for Pears now, though we have seen numbers so grafted. Though belonging to the same natural family, it is rather far removed from the Pear.

KEEPING MICE FROM PEAS (A Novice).—We know no better plan for keeping mice from Peas fresh sown than to put the Peas in a basin, make them slightly damp with a few drops of water, and then sprinkle them with a little red lead dust. Very little will do for a quart of Peas if you turn them over well with a stick until all are red-coloured. Barley awns along the rows will help to deter; but the best simple remedy is to cut up small gorse or furze and strew it above the Peas in the rows before covering with soil.

PEAS—SOWING GOLDEN PYRETHRUM (An Amateur).—We can find no list of Peas in the number for October 15th, to which you refer. We would advise you to sow the Golden Pyrethrum in March in a little heat, prick off, grow, and harden off before planting out.

WILL MICE DEVOUR DAHLIA TUBERS? (Quiz).—We have not found mice eat the roots of Dahlias when stored away for the winter.

CHRYSANTHEMUMS MILDEWED (A Novice).—You may safely take cuttings from plants that have been infested with mildew. We think the mildew a result of an insufficient supply of water at the roots during the summer, and had you given liquid manure once or twice a week, and kept the heads thin and the plants not too close together, the mildew would not have

shown itself. Dusting with flowers of sulphur is the best remedy; it will not only check but destroy the parasite.

CHRYSANTHEMUM FLOWERS IMPERFECT (W. H.).—The flowers are imperfect, and yet we think they will improve and expand better than you anticipate. Afford an abundance of air, keeping cool but safe from frost, and apply liquid manure at every alternate watering until the flowers are fully expanded.

VINES INFESTED WITH THRIPS (A Young Beginner).—The thrips will not interfere with next year's crop, providing their attacks this year did not injure the foliage seriously; but if they caused the foliage to become prematurely yellow, and to fall earlier than usual, it is likely the eyes will not be so fully formed as they ought to be, nor the wood so mature as desirable, and that will to some extent prejudicially affect the Vine's next year's produce. You will do well to not only clean and paint the Vines before starting them again, but also wash all the woodwork with soap and hot water, and thoroughly clean the glass with water only, for soap ought not to come near glass, and give the walls a thorough lime washing. The Vines ought to have the loose bark taken off, and may be coated with a solution of Clarke's Compound at the rate of 3 oza. to the gallon—a better dressing than that of soft soap and sulphur, &c., and much less unsightly.

FIG FOR POT CULTURE IN A VINERY (Idem).—The best Fig, where one kind only is required, is the Brown Turkey. If you wish for a white sort, White Marcellus will suit you.

PLANTS FOR BASKETS IN ROOM WINDOWS (W. D.).—A few good plants for suspended basket for windows are *Convolvulus mauritanicus*, *Alyssum variegatum*, Ivy-leaved Pelargoniums with pink, white, and scarlet flowers, and silvery and golden variegation; *Linnæa cymbalaria* and its white variety, *Lobelia speciosa*, *Gordonia*, *Trentham Blue*, and Miss Murphy, *Lithospermum frutescens*, *Tradescantia zebrina argentea*, *Nierembergia gracilis*, *axifraga sarmentosa*, *S. Fortuni* variegata, *Vinca elegantissima*, and the small-leaved green and variegated Vines.

DIVIDING MASSES OF EUPHARIS AND VALLOTA (C. M. Major).—We must have mislaid your letter, but have no recollection of it. The best time to divide these plants is in February or early in March, they being kept cool and dry during the winter, encouraging them with a slight increase of temperature after dividing and potting, so as to promote speedy re-establishment.

PROPAGATING BERBERIS NEPALENSIS (Idem).—Failing seeds, the only plan will be to layer the long straggling shoots. If you do this between now and spring, the bending of the head will probably give you shoots from near the base of each plant, and you may secure a plant from the top and shoots from the bottom. We are not aware that they are propagated by cuttings. The shoots layered should have a cut made in them immediately below a joint, and in an upward direction, on the lower side, and about half way through the shoot. Make the head secure with a stick, and finally peg in the soil. If you cut them down, fresh shoots will come from the base of each.

SCALE ON ARBESIA (J. D.).—You may syringe the plants and the berries with a solution of Clarke's Insect-destroying Compound, which will destroy the scale without injury to the plant or berries; 2 oza. to the gallon of water will be a sufficiently strong solution, but not too strong. The parts where the scale is should be thoroughly wetted with the solution.

PRUNING ORANGE TREES (Idem).—The best time to prune Orange trees is in February, or before they begin to grow, cutting out the old and weak wood.

DISTURBING THE GROUND BETWEEN RASPBERRIES (James Pim).—It is an old but a very bad practice to dig the ground between rows of Raspberries. The canes should have a good manuring now, if not already done, and for neatness it may be lightly pointed in with a fork, but a spade ought not to be used near them. The less a spade is used about fruit trees and bushes the better.

KEEPING APPLES AND PEARS (Idem).—They should be kept from air and light. Shutters should be placed in the windows to exclude the air. The room is too dry, or the fruit has been gathered too soon, or it would not have shrivelled. A few days before use, dessert Apples and Pears should have a rather warmer atmosphere, and have air and light to give flavour.

KEEPING GRAPES (Idem).—The temperature you name, 65°, is much too high. No fire heat should be used at night, except to exclude frost, employing fire heat by day with air to dry up damp. The temperature from fire heat should not exceed 50°. With the temperature you mention we are not surprised that the Grapes are becoming "soft and flabby, with skins tough," for they are being converted into Raisins.

TOP-DRESSING BEDS OF BULBS (F. J.).—The top-dressing of the beds with good rotten manure to the depth of an inch is excellent. It will be a good protection, and the roots will not be too deeply buried, as before winter is over the top-dressing will be considerably reduced. When the foliage appears you may, for neatness, point in the manure with a small fork or trowel. The depth of planting bulbs is calculated from the crown or summit. They are to be covered with soil to the depth named for each sort above the crown.

DIGGING FLOWER BORDERS (Idem).—Now is the best time for digging flower borders and re-arranging the plants. The border should have a good manuring if the ground is poor, and after re-arranging, the surface may have a top-dressing of leaf mould or well-rotted manure. Whilst the plants are up let the ground be well and deeply dug, trenching if necessary.

CYCLAMENS AFTER FLOWERING (Beta).—Your Cyclamens are, from your description, *C. neapolitanum*; the flowering being now just over, a number of leaves are appearing. It is hardy; but as you have hitherto kept it in the greenhouse you may still do so, letting it have the coolest and most airy situation, and one well exposed to light. Water should be supplied copiously, so as to keep the soil moist, and if the plants are in small pots shift them into larger ones, draining the pots well. The plants will continue to grow all the winter, making very ornamental foliage; and you must supply them with water until the leaves begin to turn yellow, then place the plants out of doors in a rather shady situation, plunging the pots to the rim in coal ashes; or you may plant them out in good, rich, rather light, well-drained soil, and so that the crowns will be covered

about 1½ inch with soil. When grown in pots the crowns of the corms should be covered about an inch with soil.

PROPAGATING CHRYSANTHEMUMS (Ignorance).—Having no glass, except a window, we would advise the propagation to be deferred until March, then divide the old plant, choosing the strongest suckers, and not leaving more than one or two shoots to each root. These should be planted 2 feet apart every way in ground deeply dug and well manured. After planting, water if dry weather prevail. When the plants have grown to a height of 9 or 10 inches peg them down. This saves tying up, and causes them to bloom when shorter, and to have better foliage. In hot dry weather they must be well watered three times a-week. A sheltered situation should be selected.

CUCUMBERS AND VEGETABLE MARROWS (Idem).—None of the large Cucumbers would succeed as you propose to grow them, and they would do little good trained to stakes or a trellis in the open ground; but if you have a wooden fence you may train the shoots to that, the situation being open and with a southern exposure. The same remarks apply to Vegetable Marrows; they will do well trained to a wooden fence or trellis, having a sheltered, warm, open situation. Stockwood Ridge Cucumber and Long White Vegetable Marrow will suit you.

DIOSCOREA BATATAS CULTURE (H. H.).—By leaving the rhizomes in the ground you will have them larger at the end of two years than at the end of twelvemonths. Except in very favourable soils and situations, two seasons' growth are required to secure their fine.

THREE CARNATIONS FOR WINTER BLOOMING (W. B. Jun.).—Perfection, white ground, bizarre flakes of purple and crimson; Queen of Whites, white; Jean Bart, salmon scarlet; Virgile, yellow ground, flamed and tipped with cherry; Victor Emmanuel, yellow, rosy crimson flake; Nelson, straw-flaked pink; Beauty, white, rosy pink narrow stripe; Le Géant, blood red; Oriflamme, red, and orange yellow; Magenta, purple lilac; Garibaldi, purple violet; and Victorie, scarlet and crimson flake.

VINES INFESTED WITH MEALY BUG (Try).—The rods should have all the loose bark removed, scraping the angles and probing well the holes; but be careful not to scrape or cut them into the quick or live parts of the stems, rod, or spurs. This done, wash them thoroughly with a solution of Clarke's Insect-destroying Compound, 3 ozs. to the gallon, adding a dozen drops of spirits of turpentine to every gallon of solution, and employing a stiff brush, so as to reach every hole and crevice, taking care not to rub off the eyes. The woodwork should be thoroughly cleaned, and, if possible, painted, and the walls lime-washed, using the solution above named for mixing the lime. The washing of the Vines should be done twice, and it would be well to go over them again when the eyes are beginning to swell, as the insects, from the warmth, are then coming from their hiding places. Wash carefully, so as not to dislocate the eyes, and yet effectually, so as to dislodge the insects.

WIRE FOR PEACH TREES (Idem).—The best wire is galvanised iron, and No. 10 gauge is the most serviceable. The wires are best placed horizontally, about 4 inches apart, and half an inch from the wall, or from that to three quarters of an inch.

CLODBERRY-UMBRELLA PINE (Galloway).—It is difficult to account for the Clodberry not fruiting. Probably the soil is too rich and too moist, or not sufficiently drained. The Japanese Umbrella Pine will thrive almost anywhere, and we think yours do not from there being too much water in the subsoil; in a wet soil and situation it will not grow, though it may linger.

WATERING PELARGONIUMS AND FUCHSIAS (A. G.).—You do not state whether yours are young or old plants. If old, Fuchsias will not require any water from now up to March, if the pots are set on a floor, whence they will derive sufficient moisture to keep the wood from shrivelling. The soil in the pots ought to be dry to prevent growth, and yet the wood must not be allowed to shrivel. Old plants of Pelargoniums require similar treatment; they should be kept dry, and there may be cases where water will be needed, as when the pots are over a flue so that the soil becomes very dry, then a little water should be given to prevent the wood shrivelling. Young growing plants of both Fuchsias and Pelargoniums should be watered occasionally, and when necessary to keep the foliage from flagging, but none is to be given until the soil becomes dry, yet supply it before the leaves flag.

FRUIT TREES FOR WALLS AND GARDEN (E. L.).—The wall facing south will be suitable for Apricots, Peaches, and Nectarines; or, your wall space being limited, you may devote a part of the south wall to Plums and Pears. The north aspect will only suit the Morello Cherry and Currants, whilst on the east you may have Cherries, Plums, and Pears. In the open ground Pears on the Quince, and Apples on the English Paradise stock would succeed as pyramids and bushes, and so would Plums. Your soil being light, you must top-dress heavily with cool manure, such as cow dung, and water liberally during dry hot weather. The subsoil being clay, see that water does not lodge in it; if it do the ground must be properly drained by tile drains 3 or 4 feet deep, having a proper fall and outlet.

VINE FOR COOL HOUSE (Idem).—A suitable companion for the Black Hamburgh is Foster's White Seedling.

CLETHRA ARBOREA (Idem).—It is an evergreen shrub, a native of

Madeira, attaining a height of 8 feet, and requires a light peaty soil. It is rather pretty, having white flowers at the end of summer; but requiring, as it does, the protection of a house with a greenhouse temperature, we should be averse to having it in a limited collection.

OLEANDER INFESTED WITH SCALE (A Subscriber).—The leaves sent us were badly infested with the Oleander scale (*Aspidiotus nerii*). The leaves, if like those sent, will fall. We advise that every leaf, the stem, and shoots should be washed with a sponge in every part, and on the upper and under sides of the leaves, using a solution of Clarke's Insect-destroying Compound at the rate of 3 ozs. to the gallon, and as hot as the hand can bear.

AZALEA CULTURE (Subscriber).—From September to March, and until the flowering is over, Azaleas should be kept in a light and airy place in a house with a temperature of 40° to 45° from fire heat. After flowering an increase of temperature should be given, say 55° at night, and 65° by day, with a rise of 10° or 20° from sun heat. This temperature, with a moist atmosphere, ought to be maintained until the growth is complete and the buds set; then remove the plants to a cool airy house, affording plenty of room and light. They are propagated by cuttings, which should be put in when the young shoots attain their full length and have the base rather firm, or what is known as half ripe. They should be from 3 to 4 inches in length, cut transversely below a leaf, and have the leaves removed half way up the cuttings. Insert them round the sides of a pot placed in one of larger size, and so that the rims of both are on the same level. The cutting pot should be well drained and filled to within half an inch of the rim with sandy peat, and half an inch of silver sand on the surface. The space between the pots is to be filled with crocks to within an inch of the rim, and then finish off with silver sand. Insert the cuttings up to where the leaves are left, give a gentle watering, and when dry cover with a bell-glass, which will rest on the sand between the pots. Plunge the pot in a hotbed of from 70° to 75°, keeping close and shaded. The cuttings will be well rooted in six weeks; then remove the bell-glass, commencing to remove it by degrees about a fortnight previously, by tilting it on one side. When the young plants are well hardened off put them singly in small pots, and keep them in a gentle heat until they are well established; then remove them to a cool house or greenhouse. Peat soil is necessary for the successful cultivation of Azaleas—two-thirds peat, one-third loam, and one-sixth each of old cow dung and silver sand will grow them well. Scale on the plants may be destroyed by placing them out of doors in summer, but that being injurious, unless they are carefully attended to with water, and not practicable now, syringe them with a solution of Clarke's Compound, 2 ozs. to the gallon, which will destroy the scale, the plants being thoroughly wetted in every part. When growing and flowering, Azaleas require to be plentifully supplied with water, and at other times the soil must be kept moist, but only apply water when the soil is becoming dry, and before the foliage flags, then give enough to show itself at the drainage. You may safely fumigate the house with tobacco. It will not injure the plants, but let the foliage be dry.

PLANTING VINES (T. J.).—We would not now plant the Vines, but keep them in the pots as they are until the end of February, and as cool as possible without exposing them to frost. The case or frame over the border outside will answer well for them, and the temperature may be cool, and yet not lower than 32°, nor more than 40° by allowing the pipes to become heated. In planting, the roots should have all the soil shaken away, and they should be disentangled and laid out straight, spreading them well out. Avoid deep planting. Cover the roots with 3 inches of fine loam—best from old turf, and give a gentle watering. By all means plant the Vines inside if you can, and do not on any account turn them out in winter. The Vines will not sustain any injury so long as the temperature from fire heat does not exceed 40°, and it will be all the better for the plants. The frame outside will answer for winter-bedding plants, and you may, whether there are plants in it or not, have a little heat in it in severe weather to keep out frost, but do not raise the temperature to more than 40° from fire heat.

FAILURE OF CHRYSANTHEMUMS (St. Bridget).—There are no Chrysanthemums perfectly hardy. The large-flowering are quite as hardy as the Pompons, but both kinds require to be protected, or under glass, to be safe—the month of November is so uncertain, sometimes mild and at other times frosty. The Chrysanthemum will bear 3° or 4° of frost, but this year we have had 12° and 14°, and that is the reason of your failure.
